BOX 2 Advice for Avoiding the Bites and Attacks of Common Pets

Dogs
- Do not leave a young child alone with a dog.
- Never approach or try to pet an unfamiliar dog, especially if it is tied up or confined.
- Always ask the dog's owners if you can pet the dog.
- Do not lean over a dog or pet it directly on the head.
- Do not kiss a dog.
- Avoid quick or sudden movements that may startle a dog.
- Never pet or step over a sleeping dog.
- Never try to take a bone or toy away from a dog (other than your own dog).
- Know the appearance of an angry dog: barking, growling, snarling with teeth showing, ears laid flat, legs stiff, tail up, and hair on the back standing up.
- Never step between two fighting dogs; if you need to separate them, use a bucket of water or a hose.
- Do not approach a female dog that is nursing her pups.
- Teach injury prevention advice to children from an early age.

Cats
- Be aware that some cats do not like prolonged petting.
- Know warning signs of an impending bite: twitching of the tail, restlessness, and "intention" bites (i.e., the cat moves to bite but does not bite).

Ferrets
- Do not sell or adopt a ferret that is known to bite.
- Do not push your fingers through the wires of a ferret cage.
- Reach for a ferret from the side with the palm upward rather than from above.
- Do not handle food and then handle young ferrets without washing your hands first.
- Do not poke a ferret or pull on its tail or ears.
- Never leave a ferret alone with a child or infant.
- If a ferret bites and locks on very tightly, pour cold and fast-running water over its face.

From Auerbach P: *Wilderness medicine, expert consult,* premium edition—enhanced online features and print, Philadelphia, 2012, Elsevier.

entered, and pathogenicity of inoculated bacteria.
- Punctures that are difficult to irrigate adequately, carnivore bites over vital structures (arteries, nerves, joints), and tissue crushing that cannot be debrided have a worse prognosis.
- In general, human bites have a higher complication and infection rate than do animal bites.
- Nearly 50% of the anaerobic gram-negative bacilli isolated from human bite wounds may be penicillin resistant and beta-lactamase positive.

PREVENTION

Box 2 provides advice for avoiding the bites and attacks of common pets.

REFERRAL

- Hospitalization and IV antibiotic therapy for infected human bites; bites with injury to joints, nerves, or tendons; or any animal bites unresponsive to oral therapy.
- Human bites with tendon involvement should go to operating room for washout.
- In the outpatient setting, bite wounds should be reevaluated within 48 hr to assess for signs of infection.

Animal and Human Bites (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

SUGGESTED READING

Ellis R, Ellis C: Dog and cat bites, *Am Fam Physician* 90(4):239-243, 2014.

BASIC INFORMATION

DEFINITION

There are two major classes of arthropods: insects and Arachnida. This chapter focuses on the class Arachnida. Arachnid bites consist of bites caused by:

- Spiders
- Scorpions
- Ticks

ICD-10CM CODES

T63.301	Toxic effect of unspecified spider venom, accidental (unintentional), initial encounter
T63.2	Toxic effect of venom of scorpion, accidental (unintentional), initial encounter
E906	Bite of nonvenomous arthropod; insect bite, not otherwise specified

EPIDEMIOLOGY & DEMOGRAPHICS

- Spiders—ubiquitous; only three types potentially significantly harmful:
  1. Sydney funnel web spider—Australia
  2. Black widow (Fig. E1)—worldwide (excluding Alaska)
  3. Brown recluse (Fig. E2)—most common (South Central U.S.)
- Scorpions—various warm climates: Africa, Central South America, Middle East, India; Texas, New Mexico, California, and Nevada in the U.S.
- Ticks—woodlands

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Spiders:

- Sydney funnel web—atracotoxin toxin
  1. Piloerection, muscle spasms leading to tachycardia, hypertension, increased intracranial pressure, coma
- Black widow—females toxic
  1. Initial reaction: Local swelling, redness (two fang marks) leading to local piloerection, edema, urticaria, diaphoresis, lymphangitis
  2. Pain in limb leading to rest of body (chest pain, abdominal pain), compartment syndrome
- Brown recluse
  1. Minor sting or burn
  2. Wound may become pruritic and red with a blanched center with vesicle (Fig. E3). Can necrose, especially in fatty areas (Fig. E4). Leaves eschar, which sloughs and leaves ulcer; can take months to heal
  3. Systemic symptoms: Headache, fever, chills, gastrointestinal upset, hemolysis, renal tubular necrosis, disseminated intravascular coagulation possible

Scorpions:

- Sting leading to sympathetic and parasympathetic stimulation: Hypertension, bradycardia, vasoconstriction, pulmonary edema, reduced coronary blood flow, priapism, inhibition of insulin
- Also possible: Tachycardia, arrhythmia, vasodilation, bronchial relaxation, excessive salivation, vomiting, sweating, bronchoconstriction, pancreatitis
- Clinically significant scorpion envenomation by *Centruroides sculpturatus* produces a severe neuromotor syndrome and respiratory insufficiency that often requires ICU admission

Ticks: U.S., Europe, Asia

- Very small (<1 mm). Must be attached >36 hr to transmit disease
- Lyme disease—most common (see "Lyme Disease"). Caused by the bacterium *Borrelia burgdorferi* and is transmitted to humans through the *Ixodes scapularis* tick
  1. Early localized (days): Erythema migrans in 60% to 80% of cases
  2. Early disseminated (weeks): Mild to moderate constitutional symptoms, secondary skin lesions, fever, adenopathy, facial palsy, peripheral neuropathy, lymphocytic meningitis, meningoencephalitis, cardiac manifestations (heart block)
  3. Late (months to yrs): Chronic arthritis, dermatitis, neuropathy, keratitis
- Babesiosis (see "Babesiosis")
- Ehrlichiosis/anaplasmosis (see "Ehrlichiosis and Anaplasmosis")

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Urticaria

Other tick-borne illnesses:

- Babesiosis
- Tick-borne relapsing fever/*Borrelia miyamotoi*
- Tularemia
- Rocky Mountain spotted fever
- Ehrlichiosis/anaplasmosis
- Colorado tick fever
- Tick paralysis, Powassan disease
- Community-acquired cutaneous methicillin-resistant *Staphylococcus aureus*

WORKUP

Physical examination: Thorough skin examination may reveal fang marks, attached ticks, black eschar.

TREATMENT

ACUTE GENERAL Rx

Spiders:

- Sydney funnel web
  1. Pressure, immediate immobilization, supportive care, antivenin
- Black widow
  1. Treatment based on severity of symptoms; bite is rarely fatal
  2. All should receive oxygen, IV, cardiac monitor, tetanus prophylaxis
  3. Symptomatic/supportive therapy
  4. 10% calcium gluconate for muscle cramps (controversial)
  5. Antivenin only for more severe reactions; it carries a risk of anaphylaxis
     a. Dose: One vial in 100 ml 0.9% saline over 20 to 30 min
     b. Skin test before use
     c. Give antihistamines with use
- Brown recluse
  1. Pain management, tetanus, supportive treatment
  2. No consensus regarding best treatment; some evidence for hyperbaric oxygen

Scorpions:

- Fluids, supportive care, species-specific antivenin (equine based, risk of serum sickness) is controversial.
- IV administration of scorpion-specific F(ab')2 antivenin has been reported effective in resolving the clinical syndrome within 4 hours and reducing the need for concomitant sedation with midazolam and reducing the levels of circulating unbound venom.

Ticks:

- Prophylactic: Tick >36 hr: Single dose of doxycycline 200 mg
- Early localized disease
  1. Duration of antibiotics: 10 to 21 days
  2. Doxycycline preferred in patients with possible concurrent ehrlichiosis
  3. Treatment of choice in children: Amoxicillin for 14 days
- Early disseminated: Treatment depends on manifestation
- Late disease: May require longer-term or IV therapy; controversial for neurologic disease (see "Lyme Disease")

DISPOSITION

- For patients with systemic reactions, send home with emergency epinephrine kit.
- If severe or anaphylactic reaction, admit and observe for 48 hr for cardiac, renal, or neurologic problems.

REFERRAL

For patients with systemic reactions, refer to allergist for immunotherapy; 95% to 98% effective in preventing anaphylaxis.

PEARLS & CONSIDERATIONS

Actual spider bites rare; need witnessed bite. Patient should bring spider, if possible, for confirmation. Bites usually occur in settings of unusually close contact with spider. Bedbugs becoming more prevalent; repeated exposure increases severity of reaction.

BASIC INFORMATION

DEFINITION

Most stinging insects belong to the Hymenoptera order and include the winged: honey bees, hornets, bumblebees, sweat bees, wasps (including yellow jackets), and the unwinged: harvester ants, fire ants, and the Africanized honey bee ("killer bee"). Thousands of species can sting or bite. Wasps cause 70% of all reactions to stings. Spiders, which are arachnids, not insects, are another cause of bites (Fig. 1) (see "Bites and Stings, Arachnids"). The venom of the Hymenoptera order (Fig. 2) contains vasoactive and proinflammatory mediators that can cause local reactions. A small number of those stung can develop a systemic hypersensitivity reaction. Bites differ from stings due to the injection of venom. The usual local effect of a sting is intense pain, immediate erythema, edema, and pruritus from the injecting venom. Allergic reactions can be either local or generalized. Generalized reactions can lead to anaphylactic shock. This is a rapid-onset event and can cause death. The majority of reactions occur within the first 6 hr after the sting or bite, but a delayed reaction may occur up to 24 hr after the sting. Delayed reactions are rare and include serum sickness (fever, malaise, urticaria, and arthralgias). A biphasic reaction can occur.

SYNONYM

Venom allergy

ICD-10CM CODES

T63.424	Toxic effect of venom of ants, undetermined, initial encounter
T63.444	Toxic effect of venom of bees, undetermined, initial encounter
T63.464	Toxic effect of venom of wasps, undetermined, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (OF BEE STINGS AND INSECT BITES):

- Unknown prevalence, very underreported; can be cause of outdoor sudden death; 56% to 94% of the population has been stung at least once.
- Account for 2.3% of ED visits; 5% to 7.5% of the population is hypersensitive, with large local or systemic reactions to the venom of one or more stinging insects.
- Insect bites are the most common cause of anaphylaxis reactions and account for 20% of all anaphylaxis-related deaths.
- Most anaphylactic reactions occur during summer months in those most likely to be exposed, including children, males, and outdoor workers. There are no tests to predict reaction accurately; the reaction to a prior sting is still the best predictor. Anaphylaxis can occur after a number of uneventful stings.
- Approximately half of fatal reactions occur without prior allergic response.
- Bites by fire ants are less likely to cause systemic disease.
- Spider bites are rare; only a few of the thousands of spider species cause a reaction in humans. Observation and collection of the spider inflicting the bite is necessary (see Bites and Stings, Arachnids).
- Well syndrome, a rare eosinophilic inflammatory skin disorder, can be triggered by a bite or sting.

INCIDENCE (IN U.S.): 40 to 100 people die each yr from insect sting anaphylaxis; anaphylaxis occurs most often within 10 to 30 min of a sting. Delayed reactions are rare, occurring only in <0.3% of stings.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Stings:
  1. Local reactions:
     a. Cutaneous: The skin is the most common site of a local allergic reaction. Manifestations include flushing, urticaria, pruritus, and angioedema. Local reactions may last several days. Location of sting does not increase risk of a systemic reaction.
  2. Systemic reactions:
     a. Local swelling greater than 10 cm is associated with increased risk of a systemic reaction with repeat exposure.
     b. Respiratory: This is the leading cause of anaphylactic death. Anaphylaxis as defined by consensus of the National Institutes of Health (NIH) 2006 is a severe life-threatening hypersensitivity reaction. Symptoms of upper or lower airway obstruction including hoarseness, choking, throat tightness or tingling that may progress to stridor, laryngeal edema, laryngospasm, and bronchoconstriction.
     c. Cardiovascular: Cardiac manifestations are the second leading cause of death from anaphylaxis; the most common reaction is hypotension that can progress to profound hypovolemic shock. Tachycardia and arrhythmia may occur. Myocardial infarction is rare.
     d. General symptoms: Abdominal pain, nausea, vomiting, lightheadedness, and diarrhea.

Fire ant bites:

- Initial wheal and flare response
- Subsequent development of circularly arrayed blisters within 24 hr (Fig. E3)
- Blisters may develop the appearance of pustules, but they are not infected

Flea bites:

- Classic linear configuration (Fig. E4)
- Multiple excoriated, clustered red papules (Fig. E5)

ETIOLOGY

Stings:

- Most systemic reactions to insect stings are classic immunoglobulin E (IgE)–mediated reactions. Anaphylaxis can be the presenting sign of indolent mastocytosis.
- Reactions occur in previously sensitized patients who have produced high titers of IgE antibody to insect venom antigens.
- Sensitization to wasp venom can occur after a single sting but is more common after a few stings.
- Sensitization to bee venom occurs mainly in people who have been stung frequently by bees.

In Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.)

Bites:
- Fire ant venom contains proteins toxic to the skin.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS
- Stings: Cellulitis, bites, rash
- Bites: Stings, cellulitis

WORKUP
The history is essential for accurate diagnosis including timing of sting or bite and type of insect (bee, wasp, spider, or ant) if known.

LABORATORY TESTS (FOR HYPERSENSITIVITY REACTION)
- Skin test: Either skin prick test or intradermal method with fire ant or hymenoptera venom
- Venom skin tests and occasionally radioallergosorbent tests (RAST) to provide additional information, only for those with history of a systemic reaction
- Venom-specific IgE tests
- Basophil activation tests and mast cell mediator testing are being developed to identify those with allergy and predict those who will have more severe reactions
- Measuring baseline serum tryptase can identify patients as high risk for anaphylaxis and those with mastocytosis

Rx TREATMENT

ACUTE GENERAL Rx
Sting:
- Local Poison Control Center can be contacted.
- Removal of the stinger most easily performed with a flat tool such as a credit card within 30 seconds of the sting, followed by cleansing and application of ice.
- Venom may all be released within 20 seconds of bite or sting.
- Avoid squeezing, which may push venom out of the venom sac and into the tissue.
- Supportive care with oral antihistamines, nonsteroidal antiinflammatory medications/pain medications, topical corticosteroids for 5 to 7 days, and cold compresses for limited reactions.
- Large local reactions (LLR>10 cm) may benefit from oral steroids. 50 mg/day prednisone for 5 to 7 days. Oral second-generation antihistamine can treat and prevent this reaction as well as high potency topical steroids. Unknown if future reactions will be severe.
- Patients with previous reactions or multiple stings to the mouth or neck should be evaluated in an emergency department.
- Unusual reactions to multiple stings include cerebrovascular accident or acute kidney injury due to many causes, including hypotension or direct toxicity from venom.
- Systemic reactions = Anaphylaxis: Treat quickly with intramuscular epinephrine (no contraindication for use). Increased risk of death if epinephrine delayed. The patient should be supine with 0.30 mg IM in anterior/lateral thigh. Patient should be observed for 4 to 8 hr. Adults with preexisting cardiovascular (CV) disease are at greater risk due to challenges handling the stress.
  1. H1- and H2-blockers, oxygen, IV glucocorticoids, beta-agonists, pressors, and IV fluids may also be beneficial for anaphylaxis. No data that glucocorticoids improve clinical outcomes.
  2. Patients should be given 2 units of self-injectable epinephrine pens for home use and referral to allergy indicated after a systemic reaction. Patients should be transported to ED if epinephrine is used, due to 20% risk of recurrence of symptoms.
- Tetanus not needed.

Bite:
- Supportive care—wash with soap and water
- Application of ice or cooling. Calamine lotion may be helpful
- Surveillance for secondary cellulitis—more common with yellow jacket bites

DISPOSITION
Sting:
- Prognosis for a limited reaction is excellent.
- Subsequent anaphylaxis may occur in up to 65% of patients stung again with history of prior systemic reaction. Large local reaction does not predict a systemic reaction.
- There is no evidence that the next sting will necessarily cause a more severe reaction. Variable outcome is due to the patient's age, comorbidities, time elapsed since prior exposure, dose of venom injected, and site of sting.
- Watch for secondary cellulitis.
- Patients who have a history of a severe systemic reaction should:
  1. Be educated to avoid stinging insects.
  2. Carry two syringes preloaded with epinephrine for self-administration.
  3. Undergo testing for serum levels of venom-specific IgE.
  4. Be referred to allergist for venom immunotherapy (VIT), which reduces chance of serious allergic reaction from 60% to <5%. VIT is typically needed for 3 to 5 yr.
  5. Carry medical identification for stinging insect hypersensitivity.
  6. Have a baseline tryptase level checked if an anaphylactic reaction to a sting has been experienced in the past to evaluate the possibility of an underlying mast cell disorder. Patients with levels >20 ng/ml need further evaluation. VIT may benefit those with mastocytosis and wasp venom allergy.
  7. Strategies to avoid bites and stings: No food outside, no garbage or open doors/windows near home, no fragrances or use of public outdoor toilets.

Bite:
- Prognosis for fire ant bite is excellent.
- Large lesions from brown recluse spider bites may take months to heal.
- Watch for secondary cellulitis.

REFERRAL
- Consider referral to an allergist for VIT. All patients with severe systemic reactions should be referred for testing and, if positive, should receive VIT for 5 yr.
- Risk of subsequent anaphylaxis with immunotherapy falls to <5%.
- VIT for 5 yr induces long-term protection in most patients.

! PEARLS & CONSIDERATIONS

Hypersensitivity to stings is common. Reactions range from local nonallergic reaction to venom to life-threatening systemic reaction with anaphylaxis. This could indicate underlying mast cell disorder; tryptase level is indicated. Venom-specific immunotherapy is highly effective in decreasing subsequent anaphylaxis. Venom immunotherapy is currently indicated for systemic reactions, and there is efficacy for prevention of large local reactions, which can result in significant morbidity.

BASIC INFORMATION

DEFINITION

Injury resulting from a snake biting a human.

ICD-10CM CODES

T63.0	Toxic effect of snake venom
T63.001A	Toxic effect of unspecified snake venom, accidental (unintentional), initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

- The CDC reports that, between 1950 and 2010, there were on average 5000 snakebites annually, which correlates to 1.56 bites per 100,000 people. In the U.S. alone, there are five cases of snake bites resulting in death per yr. Data from the National Electronic Injury Surveillance System reveals that the number of snakebites (including from nonvenomous snakes) between 2001 and 2010 was close to 9200 on average per yr, with more than 2800 venomous bites per yr.
- The highest incidence is reported in southern states, especially Texas and Florida.
  1. Snakebites peak during the warmer months of April through November.
  2. Worldwide, farm workers have the highest incidence of snakebites. In the U.S., most snakebites result from intentional provocation of wild snakes or in the setting of handling captive snakes.
  3. In the U.S., 13.9% of bites occurred predominantly in landscapers, snake handlers, and outdoor professionals, with 76% of the envenomations involving the upper extremity.
  4. The sex ratio (male:female) is 2.7.
  5. Incidence peaks in those between 10 and 14 yr of age and then steadily decreases in adults to about 2 bites per 100,000. Alcohol use and drug intoxication are implicated in many snakebites. The risk of death is highest in children, the elderly, and in those with delayed presentation to care.
  6. Exotic, nonnative pets also account for 1% to 2% of snake envenomations.
- In the U.S., at least one species of poisonous snake (Fig. E1) has been identified in every state, with the exception of Alaska, Hawaii, Rhode Island, and Maine. Table E1 summarizes medically important snake families.
- The Viperidae family includes the Crotalinae subfamily which is the only subfamily native to North America. These are commonly referred to as crotalids or pit vipers and include rattlesnakes, copperheads, and cottonmouths (water moccasins).
  1. Crotalids are responsible for 98% of snake envenomations in the U.S.
  2. Crotalids are characterized by a prominent, diamond-shaped head, a heat-sensing pit between the eye and nostril, long retractable fangs, and, in the case of rattlesnakes, the telltale rattler.
  3. Crotalid bites are typically very painful. Their venom contains a hemotoxin, a neurotoxin, a cardiotoxin, and necrotizing factors leading to direct tissue damage and necrosis. Dry bites (when envenomation does not occur) make up approximately 3 to 25% of pit viper bites.
- The Elapidae family includes mambas, cobras, and coral snakes.
  1. Coral snakes are the only member of the Elapidae family found in the U.S.
  2. Coral snakes are much less common than crotalids, are innately less aggressive, and represent only 2% of reported snakebites in the U.S.
  3. Elapids have smaller heads and shorter fangs, and they are identified by vibrant bands of yellow, red, and black. The popular saying "Red on yellow, kill a fellow; red on black, venom lack" is used to distinguish between venomous and nonvenomous snakes in the U.S. Caution should be used when applying this axiom internationally, as some coral snakes within South America display red-on-black coloring and are in fact venomous.
  4. Because of their shorter fangs, elapids rely on a longer bite time to inject their venom. Less than 40% of coral bites result in envenomation.
  5. The elapid venom competitively blocks the acetylcholine receptor leading to a delayed onset of systemic symptoms. The venom lacks proteolytic enzymes so there is minimal soft tissue destruction. In the last 40 yr, there has only been 1 fatality from a coral snake bite, and this was because the patient did not seek treatment.

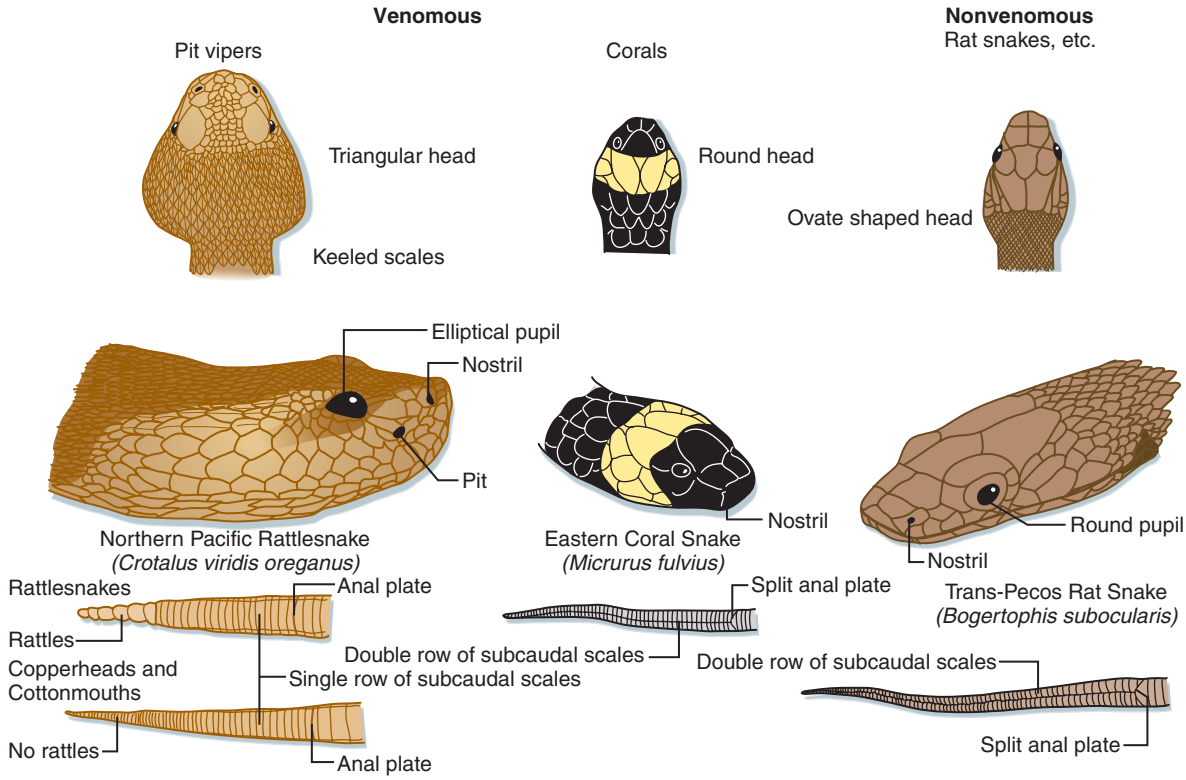

FIG. E1 Anatomic comparison of pit vipers, coral snakes, and nonvenomous snakes of the United States. (Modified from Adams JG et al [eds]: *Emergency medicine,* Philadelphia, 2008, WB Saunders. Drawing by Marlin Sawyer. In Kliegman, RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2019, Elsevier.)

TABLE E1 Medically Important Snake Families

Family	Venomous?	Location	Examples	Toxin Effects/Other Comments
Colubridae	Some species	Most parts of the world	Garter snakes (*Thamnophis* spp.), king snakes, and milk snakes (*Lampropeltis* spp.)	Largest family of snakes; most are considered harmless to humans; a few species are dangerously toxic (e.g., African boomslang [*Dispholidus typus*])
Boidae	None	Most parts of the world	*Boa* sp., *Python* sp.	Constrictors; unsupervised children should not be allowed access to large constrictors
Viperidae				
Subfamily Crotalinae (pit vipers)	All	Americas, Asia	Rattlesnakes (*Crotalus* spp.), cottonmouths, and copperheads (*Agkistrodon* spp.), Lancehead pit vipers (*Bothrops* spp.)	Heat-sensing "pit" between each eye and nostril
Subfamily Viperinae (true vipers)	All	Europe, Africa, Middle East, Asia	Puff adder (*Bitis arietans*), Gaboon viper (*Bitis gabonica*)	No heat-sensing pits
Elapidae	All	Americas, Africa, Middle East, Asia	Cobras (*Naja* spp.), mambas (*Dendroaspis* spp.), kraits (*Bungarus* spp.), coral snakes (*Micrurus* spp.), and the venomous snakes of Australia	Highly variable venom effects—some largely neurotoxic, others causing severe local tissue damage
Hydrophiidae	All	Warm waters of the Pacific Ocean, Indian Ocean, and Oceania (none in the Atlantic Ocean)	Sea snakes including the pelagic sea snake (*Pelamis platurus*)	Neurotoxins and myotoxins; rarely bite humans unless provoked

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

- The degree of envenomation correlates to the size of the snake, with envenomation from larger snakes producing significantly worse local and systemic symptoms than bites from smaller animals.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The effects of envenomation vary by the type of snake but typically includes local tissue injury, coagulopathy, neurotoxicity, and cardiovascular instability, as well as renal failure. Crotalids typically cause more severe local effects as well as hematologic symptoms including primary consumptive coagulopathies and, less commonly, neurologic complications. The exception is the Mohave rattlesnake bite, where local tissue destruction following envenomation is minimal, but severe neurologic symptoms can occur up to 12 hours after the bite. This is similar to elapid bites, which cause less localized tissue damage but have more severe and often delayed neurotoxic manifestations.

CROTALINAE (PIT VIPERS): Local signs and symptoms:

- Intense pain within 5 min.
- Localized edema within 30 min.
- Erythema, ecchymosis, and serous/hemorrhagic bullae can develop over hours (Fig. E2).
- Compartment syndrome is rare but can develop around the site of the bite due to significant amounts of soft tissue swelling and subcutaneous tissue fluid accumulation.
- If edema or erythema does not occur within 8 hours of a confirmed crotalid snakebite, it is assumed envenomation did not occur ("dry bite"). Roughly 25% of crotalid bites are "dry bites."

Systemic manifestations:

- Nonspecific: Nausea, vomiting, diarrhea, lightheadedness, weakness, diaphoresis, chills
- Coagulopathy: Epistaxis, bleeding from gums, internal hemorrhage
- Neurotoxicity: Perioral paresthesias, metallic taste, tingling of fingers or toes (especially with rattlesnake bites), localized/generalized fasciculations, mental status change
- Nephrotoxicity: Secondary to rhabdomyolysis

FIG. E2 Southern Pacific rattlesnake *(Crotalus helleri)* bite wounds. (Courtesy Sean Bush, MD)

- Increased vascular permeability: Severe hypotension, tachycardia, respiratory distress

ELAPIDAE (CORAL SNAKES): Local signs and symptoms:

- Absent or minimal local effects, such as mild pain, swelling, or paresthesias at site of bite

Systemic manifestations:

- May be delayed for up to 12 hours.
- Nonspecific: Nausea, vomiting, abdominal pain, dizziness.
- Neurotoxic: Cranial neuropathies typically appear first, including ptosis, ophthalmoplegia, dysphagia, drooling, and mydriasis with absent or prolonged pupillary light reflex. Descending paralysis and respiratory failure (due to diaphragmatic weakness) can be delayed many hours.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bite: Nonvenomous snakebite, "dry bite," scorpion bite, insect bite, cellulitis, laceration, puncture wound, necrotizing fasciitis
- Descending paralysis: Myasthenia gravis, botulism, shellfish poisoning
- Rhabdomyolysis: Crush injury, prolonged immobilization, marked exercise, hyperthermia, metabolic myopathies, drugs or toxins, infections, electrolyte disorders
- Coagulopathy: Sepsis, multiple trauma, obstetrical complications, malignancy

TABLE E2 Indications for Snake Antivenom Administration

Evidence of Systemic Toxicity:	
Hemodynamic or respiratory instability	Hypotension, respiratory distress
Hemotoxicity	Clinically significant bleeding or abnormal coagulation studies
Neurotoxicity	Any evidence of toxicity: Usually beginning with cranial nerve abnormalities and progressing to descending paralysis including the diaphragm
Evidence of local toxicity	*Progressive* soft tissue swelling

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

WORKUP

- Stabilize and resuscitate unstable patients.
- Initial evaluation of the bite (see details below):
  1. Complete physical and neurologic examination.
  2. Obtain past medical history, including any history of allergic reaction to horse serum, sheep serum, or papaya in those previously treated for snakebite (see antivenom treatment). Patients with allergies to papain, chymopapain, or other papaya extracts may be at risk of an allergic reaction to crotalid antivenom.
- Labs and imaging (see details below).
- Determine need for antivenom (see the following and Table E2).
- Call Poison Control Hotline: 1-800-222-1222.
- Call local zoo when treating patients with envenomations from exotic pets or nonnative snakes.
- Serially reassess, including serial neurologic exams, all cases of suspected envenomation for 8 hours, longer if clinical status deteriorates.

LABORATORY TESTS

- Complete blood count with peripheral smear, electrolytes, blood urea nitrogen, creatinine, prothrombin time, partial prothrombin time, fibrinogen, D-dimer, creatine kinase, liver function tests, sedimentation rate, arterial blood gas, type and crossmatch, urinalysis, and electrocardiogram.
- Repeat labs every 4 to 6 hours to monitor trend.

IMAGING STUDIES

- Consider chest x-ray in cases of severe envenomation or in patients with underlying cardiopulmonary disease to rule out pulmonary edema.
- Plain films of bite site for retained fangs (poor sensitivity). Bedside ultrasound is another option to rule out a retained foreign body in the setting of snakebite (negative predictive value of 96%).
- Computed tomography (CT) of head if concern for intracranial hemorrhage or if any cognitive/neurologic deficit is recognized on exam.
- CT abdomen or focused assessment with sonography in trauma (FAST) if concern for intraabdominal bleeding exists or if patient complains of abdominal pain or distention.

Rx TREATMENT

ACUTE GENERAL Rx

IN THE FIELD:

- There is no field first aid that will significantly treat the envenomation; therefore, the most important intervention is to transport the patient quickly to the nearest medical facility.
- Remove any constricting items including rings, watches, jewelry, or tight clothing.
- The affected part should be kept at the level of the heart and neutral. Keep the joint in a functional position to minimize disability should the limb or joint become severely swollen or immobile.
- Do *not* apply a tourniquet, incise wound, apply mechanical or oral suction, attempt electrotherapy, or apply ice. These interventions have not been shown to provide any benefit and have the potential to cause further harm, including tissue damage, infection, and caregiver envenomation.
- A loose tourniquet, applied to occlude only lymphatic drainage and loosened every 60 to 90 seconds, can be applied for 10 min if the patient was bitten by a coral snake or other species with neurotoxic venom and the patient is exhibiting neurologic symptoms or there is a prolonged transport time. A properly applied pressure bandage should produce a pressure of 40 to 70 mm Hg and 55 to 70 mm Hg in the upper and lower extremity, respectively. Overall, this is not a recommended technique.
- Avoid alcohol, stimulants (caffeine), or agents that can suppress mental status.
- Do *not* pick up a dead snake, as the strike reflexes remain intact and can still envenomate.
- When possible, a picture can be taken from a safe distance for later classification of the snake.

IN THE HOSPITAL:

- Assess airway, breathing, and circulation and intervene as needed. Patients with neurotoxic envenomation from elapids or Mohave rattlesnakes can develop respiratory failure (from diaphragmatic paralysis) and may require intubation. Perform pulmonary function tests (PFTs) and place end tidal CO_2 monitoring. Be cautious and repeat the examination as neurotoxic symptoms may be delayed for many hours.
- Place on monitor, obtain vital signs, place 2 large-bore IVs and give crystalloid.
- Unstable patients should be given antivenom immediately. Administration should not be delayed for wound care of the bite.
- In stable patients, obtain a history, including the time of bite and description of snake.
- Inspect bite site for fang marks and local tissue injury. Clean bite site and remove any retained fangs. Bite may appear like two distinct puncture wounds or small scratches.
- Mark leading edge of erythema and edema, and obtain circumferential measurements every 15 min to assess for progression.
- Obtain initial labs and repeat every 4 to 6 hours.
- Determine need for antivenom and begin preparation. It can take up to 1 hour to reconstitute antivenom, so this process should be started as early as possible.
- Contact Poison Control at 1-800-222-1222, which will connect you to your local poison control center. They will provide guidance for treatment and use of antivenom and also track snakebite incidence.
- Immunize against tetanus if no booster within the past 5 yr. If never immunized, give immunoglobulin as well as toxoid.
- Prophylactic antibiotics are not recommended. Antibiotics should be given only if purulence or other signs of infection are identified, at which time the patient should be given broad-spectrum antibiotics that cover gram-negative bacteria (i.e., ampicillin-sulbactam or quinolone derivatives).
- Aggressive pain control with opioids. Avoid NSAIDs as they increase risk of bleeding, platelet dysfunction, and nephrotoxicity.

ANTIVENOM TREATMENT

CROTALID (RATTLESNAKE, COPPERHEAD, COTTONMOUTH) ENVENOMATIONS:

- CroFab (Crotalinae polyvalent ovine immune Fab), made from sheep serum, is the antivenom commercially available in the U.S. for crotalid envenomations.
- Indications for antivenom administration include swelling, pain, and/or ecchymosis extending beyond area immediately adjacent to bite, any progression of local symptoms (≥2 cm of erythema spread), any systemic symptoms, any development of coagulation lab abnormalities, or abnormal bleeding.
- Patients with crotalid envenomation who have minimal or nonprogressive symptoms should *not* be given CroFab and instead should be monitored for 8 to 12 hours.
- Dosing:
  1. For moderate symptoms, reconstitute 4 to 6 vials of antivenom (CroFab). Each vial should be mixed in 25 ml of normal saline. The 4 to 6 reconstituted vials should then be mixed in 250 ml normal saline and infused over 60 min. Infuse the first 25 ml slowly over the first 10 min to monitor for allergic reaction.
  2. For patients with shock or serious active bleeding, give an initial dose of 8 to 12 vials.

3. If no improvement after first round (defined as progression of local symptoms, persistent systemic symptoms, derangement of laboratory values, or continued bleeding), repeat the initial dose of antivenom after 1 hour.
4. Between 4 and 18 vials of antivenom may be necessary to control initial symptoms.

- After initial control of symptom progression, give maintenance dose of 2 vials every 6 hours for 3 doses to prevent recurrent toxicity. This is because the half-life of CroFab is shorter than the venom's half-life.
- Hematologic labs (fibrinogen, platelet levels, and coagulation studies) should be repeated within an hour of antivenom administration.
- The manufacturer of CroFab maintains a 24/7 hotline: 1-877-377-3784.
- A new Crotalinae antivenom, Anavip, was approved by the FDA in May 2015 and became available in October 2018. It is only approved for rattlesnake envenomation. Anavip is an equine antivenom that has venom specific $F(ab')_2$ fragments of immunoglobulin G (IgG), as opposed to two separate Fab fragments, increasing the half-life in the blood and leading to greater binding and therefore greater elimination of the venom. Because of the longer half-life, dosing with Anavip also eliminates the need for repeat outpatient antivenom dosing, as is required with CroFab. There is a lower risk of adverse coagulopathic reactions and serum sickness because, similar to CroFab, these antivenoms lack the Fc component of the IgG.
- Dosing:
  1. For moderate symptoms, reconstitute 10 vials of antivenom (Anavip). Each vial should be mixed in 10 ml of normal saline. The 10 reconstituted vials should then be mixed in 250 ml normal saline and infused over 60 min. Infuse the first 8 ml slowly over the first 10 min to monitor for allergic reaction.
  2. If no improvement after first round (defined as progression of local symptoms, persistent systemic symptoms, derangement of laboratory values, or continued bleeding), repeat the initial dose of antivenom after 1 hour and repeat every hour as needed.
  3. Re-emerging symptoms should be given an additional 4 vials as needed.
  4. There is no known maximum dose.

ELAPID (CORAL SNAKE) ENVENOMATIONS:

- In the U.S., production of coral snake antivenom by Pfizer/Wyeth was discontinued and only one lot of Antivenin still exists (Lot #L67530). The antivenom's expiration date was extended to January 31, 2020. The use of expired antivenom may be considered in a patient with life-threatening symptoms but should only be administered in conjunction with Poison Control and/or a medical toxicologist. If coral snake antivenom is not available, providers may consider contacting their local zoo to determine whether a provisional antivenom is available. Small-animal studies support the use of black-banded coral snake (Coralmyn), tiger snake, Australia/New Guinea polyvalent antivenom, or anticoral antivenom for neutralization of North American coral snake venom. Many zoos caring for wild snake species stock these specific antivenoms. It is important to note that the effectiveness of these particular antivenoms in human snakebites by the North American coral snake has not been studied. If considering administering alternate antivenom, the provider should contact Poison Control to help orchestrate acquisition.
- In the U.S., only symptomatic patients with confirmed coral snake bites should receive antivenom. The initial dose is 3 to 5 vials given by slow intravenous push, although a higher dose may be necessary in children or in envenomations from large coral snakes.
- There is a high risk of allergic reaction with horse serum-based elapid antivenom so epinephrine, diphenhydramine, IV corticosteroids, and albuterol should be readily available prior to giving antivenom.
- If antivenom administration will be delayed, can consider anticholinesterase therapy (neostigmine) 0.5 to 2 mg by slow IV push with atropine pretreatment.

NONNATIVE OR EXOTIC SNAKE ENVENOMATIONS: Contact the Poison Control Center or your local zoo, as zoos with exotic snakes are required to maintain a supply of snake-specific antivenom on their premises.

DISPOSITION

- All patients who are given antivenom must be admitted and monitored in an ICU for further observation and supportive care. Patients should be observed for a minimum of 18 to 24 hours after initial control of symptom progression, and they are safe for discharge when symptom progression has resolved and laboratory values have normalized.
- Victims of crotalid envenomations with minimal to no toxicity and normal serial lab values should be observed for 8 to 12 hours.
- Suspected Mohave rattlesnake bites, a subset of crotalids, should be observed 12 to 24 hours, as their venom predominantly causes neurotoxicity and symptoms may be delayed (similar to elapids).
- Asymptomatic patients with coral snakebites should be observed for 12 to 24 hours because neurotoxicity may be delayed.
- Children, the elderly, those with significant comorbidities, and patients who sustain bites to the legs, face, or neck may require observation for 24 hours.

FOLLOW-UP:

- All patients who receive antivenom should have repeat labs at 2 to 3 days and 5 to 7 days after the last administered antivenom dose to evaluate for delayed hematologic complications or serum sickness.
- Return for worsening, nondependent swelling, abnormal bleeding, or signs of serum sickness, which include fatigue, rash, or arthralgias. If serum sickness develops, give prednisone 1 mg/kg/day, then once symptoms resolve taper dose over 1 week.
- Patients should adhere to bleeding precautions (no contact sports, dental extractions, elective surgery, etc.) for 2 weeks.

REFERRAL

Refer to a medical facility with an ICU for administration of antivenom. The approach to snakebites should be multidisciplinary and should include medical toxicology or other physician snakebite specialists, as well as hematology or nephrology if needed. All snakebites should be reported to Poison Control and the local health department for surveillance.

PEARLS & CONSIDERATIONS

OTHER CONSIDERATIONS

- Frequent assessment and clinical judgment is essential in the treatment of snakebites, as patients do not have a uniform response to envenomation and treatment.
- Dosage of antivenom is based on typical envenomation rather than age or weight, so the dose is the same for children and adults.
- Antivenom is most effective when given within 4 hours of the bite and least effective if delayed beyond 12 hours. Systemic symptoms (coagulopathy, CNS effects, etc.) respond better to treatment than do local symptoms (erythema/edema, bullae, etc.).
- Antivenom is not contraindicated in pregnancy. There have been no adverse reactions to mother or to fetus reported secondary to antivenom treatment. The potential coagulopathy associated with envenomation may place the fetus at higher risk for placental abruption, so prompt treatment with antivenom is prudent. Pregnant victims of snakebites who are treated with antivenom have a significantly lower rate of miscarriage when compared with those who did not receive antivenom.
- Although local wound effects can be severe, wound management should not take precedence over antivenom administration. Some studies suggest that even in the case of compartment syndrome, antivenom may be more effective than fasciotomy, although both may be necessary.

COMPLICATIONS

- Hypersensitivity reactions and serum sickness can occur following antivenom administration. These reactions are much more common with equine-derived antivenom than with ovine-derived antivenom. CroFab derived from sheep serum should be used preferentially over equine serum if available, given the decreased risk for adverse reaction. Elapid antivenom is derived from horse serum, so the risk for allergic reaction and anaphylaxis remains high.
- Anaphylaxis to antivenom can occur within 30 min and should be treated by immediately stopping the infusion and managing the symptoms. Epinephrine, diphenhydramine, and hydrocortisone should be administered

as needed. If the anaphylaxis is well-controlled and the envenomation is severe, the antivenom infusion can then be resumed.
- In patients with a known hypersensitivity to antivenom, prophylactic epinephrine has been found to reduce the rate of adverse effects.
- Delayed or recurrent hematologic complications are common and can manifest up to 2 weeks post treatment. Most bleeding is self-limited but can rarely be severe, necessitating close follow-up and occasionally repeat doses of antivenom.
- Serum sickness occurs 7 to 14 days after antivenom administration and is characterized by fever, rash, arthralgias, and lymphadenopathy. It can be treated with prednisone 60 mg PO daily, tapered over 7 to 10 days.

Snakebites (Patient Information)

AUTHORS: **Ashley A. Jacobson, MD,** and **Neha P. Raukar, MD, MS**

BASIC INFORMATION

DEFINITION

Bladder cancer is a field change disease in which the entire urothelium from the renal pelvis to the urethra is susceptible to malignant transformation. The disease stages include non–muscle-invasive bladder cancer, muscle-invasive bladder cancer, and metastatic urothelial carcinoma. The three types of bladder cancer are transitional cell carcinoma, squamous cell carcinoma, and adenocarcinoma.

ICD-10CM CODES

C67.9	Malignant neoplasm of bladder, unspecified
C79.11	Secondary malignant neoplasm of bladder
D09.0	Carcinoma in situ of bladder
D30.3	Benign neoplasm of bladder
D41.4	Neoplasm of uncertain behavior of bladder
D49.4	Neoplasm of unspecified behavior of bladder

EPIDEMIOLOGY & DEMOGRAPHICS

In 2019, an estimated 80,470 new cases and 17,670 deaths in the U.S. were attributed to bladder cancer. It is the sixth commonest malignancy in the U.S., with a median age of diagnosis of 73 yr.

PREDOMINANT SEX: It is 3 to 4 times more common in men than in women; lifetime risks are 1 in 26 for men and 1 in 88 for women.

RISK FACTORS:

Smoking:

- More than half of bladder cancers are related to smoking.
- Smoking risk is based on consumption; there is a two- to three-fold increase for subjects smoking >10 cigarettes per day.
- Smokers of low-tar and low-nicotine cigarettes have a lower risk when compared with higher tar and nicotine cigarettes.
- Those who smoke unfiltered cigarettes have a 50% increased risk of bladder cancer compared with those who smoke filtered cigarettes.
- Pipe smokers have a lower risk of bladder cancer compared with cigarette smokers.
- Cigars, snuff, and chewing tobacco, although implicated in nonurologic cancers, are not thought to influence bladder cancer risk.

Diet:

- Diets rich in beef, pork, and animal fat increase risk of bladder cancer.
- Beer consumption has been linked to bladder cancer development as a result of the presence of nitrosamines in the beer. Drinking coffee is not thought to contribute to bladder cancer risk.
- Medications: Long-term (>1 yr) use of pioglitazone and rosiglitazone.

PEAK INCIDENCE: Incidence increases with age: Higher after age 60 yr, uncommon in those younger than 40 yr.

GENETICS: It is thought to be multifactorial in etiology, involving both genetic and environmental interactions. Overall, approximately 20% to 25% of the male population in the U.S. with bladder cancer is estimated to have the disease as a result of occupational exposure.

DISTRIBUTION: In North America, transitional cell carcinomas (TCC) account for 93%, squamous cell carcinomas account for 6%, and adenocarcinomas account for 1% of bladder cancers.

PATHOGENESIS: Two pathways exist for bladder cancer (TCC):

- Papillary superficial disease occasionally leading to invasive cancer (75%)
- Carcinoma in situ (CIS) and solid invasive cancer with high risk of disease progression (25%)

Two distinct forms of "superficial cancer" exist:

- T_a: Papillary low-grade tumor with a high rate of recurrence; disease progression occurs in 5%
- T_1: Higher-grade papillary tumor that infiltrates the lamina propria; often associated with flat CIS that may involve the urothelium diffusely. Disease progression occurs in 30% to 50%. This is subdivided into:
  1. T_{1a}: Penetration up to the muscularis mucosa; disease progression in 5%
  2. T_{1b}: Penetration through the muscularis mucosa; disease progression in 53%

Flat CIS:

- Entirely different and separate pathway of cancer development whose mechanism is manifested by dysplasia, which leads to the occurrence of poorly differentiated malignant cells that replace or undermine the normal urothelium and extend along the plane of the bladder wall. It penetrates the basement membrane and lamina propria in 20% to 30% of cases and is associated with the development of solid tumor growth. A p53 defect occurs in 50% of these cases.

At presentation, 50% to 51%% of cancers are in situ, 34% to 35% are localized to the bladder, 17% are regionally spread to the lymph nodes, and 4% to 5% present with distant metastases. Eighty percent of superficial TCC recur, with up to 30% progressing to a higher stage or grade. Younger patients most commonly develop low-grade papillary noninvasive TCC and are less likely to have recurrences when compared with older patients with similar lesions. Involvement of the upper tracts with tumor occurs in 25% to 50% of cases (see Table 1 and E2).

MOLECULAR EPIDEMIOLOGY: TCC is usually a field change disease with tumors arising at different times and sites in the urothelium, suggesting a polyclonal etiology of bladder cancer. Non–muscle-invasive bladder cancer (NMIBC) and muscle-invasive bladder cancer (MIBC) are genetically different. NMIBC is characterized by a high frequency of mutations in the *FGFR* oncogene, leading to constitutive activation of the RAS/MAPK pathway. In MIBC, mutations in the *TP53* gene prevail. In general, mutations in *FGFR* and *TP53* are mutually exclusive, suggesting that NMIBC and MIBC develop along different oncogenetic pathways. However, these mutations often occur simultaneously in stage pT_1 tumors that invade the connective tissue layer underlying the urothelium. Recently, somatic mutations in the *PIK3CA* oncogene, which encodes the catalytic subunit p110α of class-IA PI3 kinase, were described in 13% to 27% of bladder tumors. These mutations often coincided with *FGFR3* mutations. Mutations in the *RAS* oncogenes (*HRAS*, *KRAS*, and *NRAS*) have also been found in 13% of bladder tumors and in all stages and grades; they are mutually exclusive with *FGFR3* mutations.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Gross, painless hematuria
- Microhematuria
- Frequency, urgency, occasional dysuria
- With locally invasive to distant metastatic disease, the presentation can include:
  1. Abdominal pain
  2. Flank pain
  3. Lymphedema
  4. Renal failure
  5. Anorexia
  6. Bone pain

ETIOLOGY

Bladder cancer is a potentially preventable disease associated with specific etiologic factors:

- Cigarette smoking is associated with 45% to 65% of cases. The risk of developing a TCC is two to four times higher in smokers than in nonsmokers, and that risk persists for many yrs, being equal to nonsmokers only after 12 to 15 yr of smoking abstinence. Smoking is associated with higher histologic grade and stage, increase in the numbers of tumors, and increased size
- Occupational exposures: Dye workers, textile workers, tire and rubber workers, petroleum workers
- Chemical exposure: O-toluidine, 2-naphthylamine, benzidine, 4-amino-biphenyl, and nitrosamines
- Exposure to herpes papilloma virus type 16

Squamous carcinomas are associated with:

- Schistosomiasis
- Urinary calculi
- Indwelling catheters
- Bladder diverticula

Miscellaneous causes:

- Phenacetin abuse
- Cyclophosphamide
- Pelvic irradiation
- Tuberculosis

Adenocarcinomas are associated with:

- Exstrophy
- Endometriosis
- Neurogenic bladder
- Urachal abnormalities
- As a secondary site for distant metastases from other organs (e.g., colon cancer)

DIAGNOSIS

- History and physical examination.
- Urinalysis.

TABLE 1 2018 TNM Bladder Cancer Stage Classification

T stage	Description
T_X	Primary tumor cannot be assessed
T_0	No evidence of primary tumor
T_a	Noninvasive papillary carcinoma
T_{is}	Carcinoma in situ
T_1	Tumor invades lamina propria
T_2	Tumor invades muscularis propria
pT_{2a}	Tumor invades superficial muscularis propria (inner half)
pT_{2b}	Tumor invades deep muscularis propria (outer half)
T_3	Tumor invades perivesical tissue
pT_{3a}	Microscopic invasion
pT_{3b}	Macroscopic invasion (extravesical mass)
T_4	Tumor invades any of the following: Prostatic stroma, seminal vesicles, uterus, vagina, pelvic wall, abdominal wall
T_{4a}	Tumor invades prostatic stroma, uterus, vagina
T_{4b}	Tumor invades pelvic wall, abdominal wall
Regional lymph nodes (N)	
N_0	No lymph node metastasis
N_1	Single lymph node metastasis in true pelvis (perivesical, obturator, internal/external iliac, or sacral lymph node)
N_2	Multiple lymph node metastases in true pelvis (perivesical, obturator, internal/external iliac, or sacral lymph node metastasis)
N_3	metastasis to the common iliac lymph nodes
Distant metastasis (M)	
M_0	No distant metastasis
M_1	Distant metastasis
M_{1a}	Distant metastasis limited to lymph nodes beyond the common iliacs
M_{1b}	Non–lymph-node distant metastases

- Cystoscopy with bladder barbotage and biopsy. Fluorescence cystoscopy offers improvement in the detection of flat neoplastic lesions such as carcinoma in situ.
- Transurethral resection of bladder tumor (TURBT).
- There is insufficient evidence to determine whether a decrease in mortality rate from bladder cancer occurs with hematuria testing, urinary cytology, or a variety of other tests on exfoliated urinary cells or other substances.
- In addition to urinary cytology and bladder barbotage, BTA, NMP22, and fibrin degradation products have been approved by the FDA as bladder cancer tumor markers. No marker has general, widespread acceptance because the results are affected by the presence of stents, recent urologic manipulation, stones, infection, bowel interposition, and prostatitis, creating false-positive results.
- Urinary biomarkers: Six urinary biomarkers have been approved by the FDA for diagnosis on surveillance of bladder cancer.
  1. Quantitative nuclear matrix protein 22 (Alere NMP22)
  2. Qualitative NMP22 (BladderChek)
  3. Qualitative bladder tumor antigen (BTA stat)
  4. Quantitative BTA (BTA TRAK)
  5. Fluorescence in situ hybridization (FISH)
  6. Fluorescent immunohistochemistry (ImmunoCyt)
- Generally, urinary biomarkers miss a substantial proportion of patients with bladder cancer and are subject to false-positive results in others. Accuracy is poor for low-stage and low-grade tumors.[1]

DIFFERENTIAL DIAGNOSIS

- Urinary tract infection
- Frequency-urgency syndrome
- Interstitial cystitis
- Stone disease
- Endometriosis
- Neurogenic bladder

WORKUP

Fig. 1 illustrates a diagnostic and treatment algorithm for bladder cancer.

LABORATORY TESTS

- Urine cytology.
- Urine telomerase: Telomerase activity in voided urine or bladder washings determined by the telomeric repeat amplification protocol (TRAP) assay. This test has been reported to accurately detect the presence of bladder tumors in men. It represents a potentially useful noninvasive diagnostic innovation for bladder cancer detection in high-risk groups such as habitual smokers or in symptomatic patients.

[1] Chou R et al: Urinary biomarkers for diagnosis of bladder cancer: a systematic review and meta-analysis, *Ann Intern Med* 163:922-931, 2015.

RADIOLOGIC TESTS

- Renal ultrasound, retrograde pyelography, CT scan, and MRI.
- One or a combination of studies can be used. In the absence of skeletal symptoms, bone scan is not recommended.

Rx TREATMENT

SURGICAL APPROACHES

- The goal of any resection should be the visual eradication of any tumor burden and the assurance of an adequate depth of resection
- Initially, transurethral resection of bladder tumor (TURBT). Using cutting current, a loop electrode is used to resect the tumor inclusive of muscularis propria (Fig. E2). Histologically, bladder tumors frequently exhibit growth beyond the visible edge, and, as such, resection should include an approximate 2-cm margin of normal-appearing tissue. Wide resection of tumors will ensure completeness, whether the tumor has a broad base or a tentacular growth pattern (Fig. E3)
- Loop biopsy of the prostatic urethra if high-grade TCC is suspected
- If superficial disease, follow-up protocol with repeat TURBT and/or the use of intravesical agents is recommended
- For advanced bladder cancer, radical cystectomy with urethrectomy (unless orthotopic diversion is planned), and either ileal loop conduit or orthotopic diversion

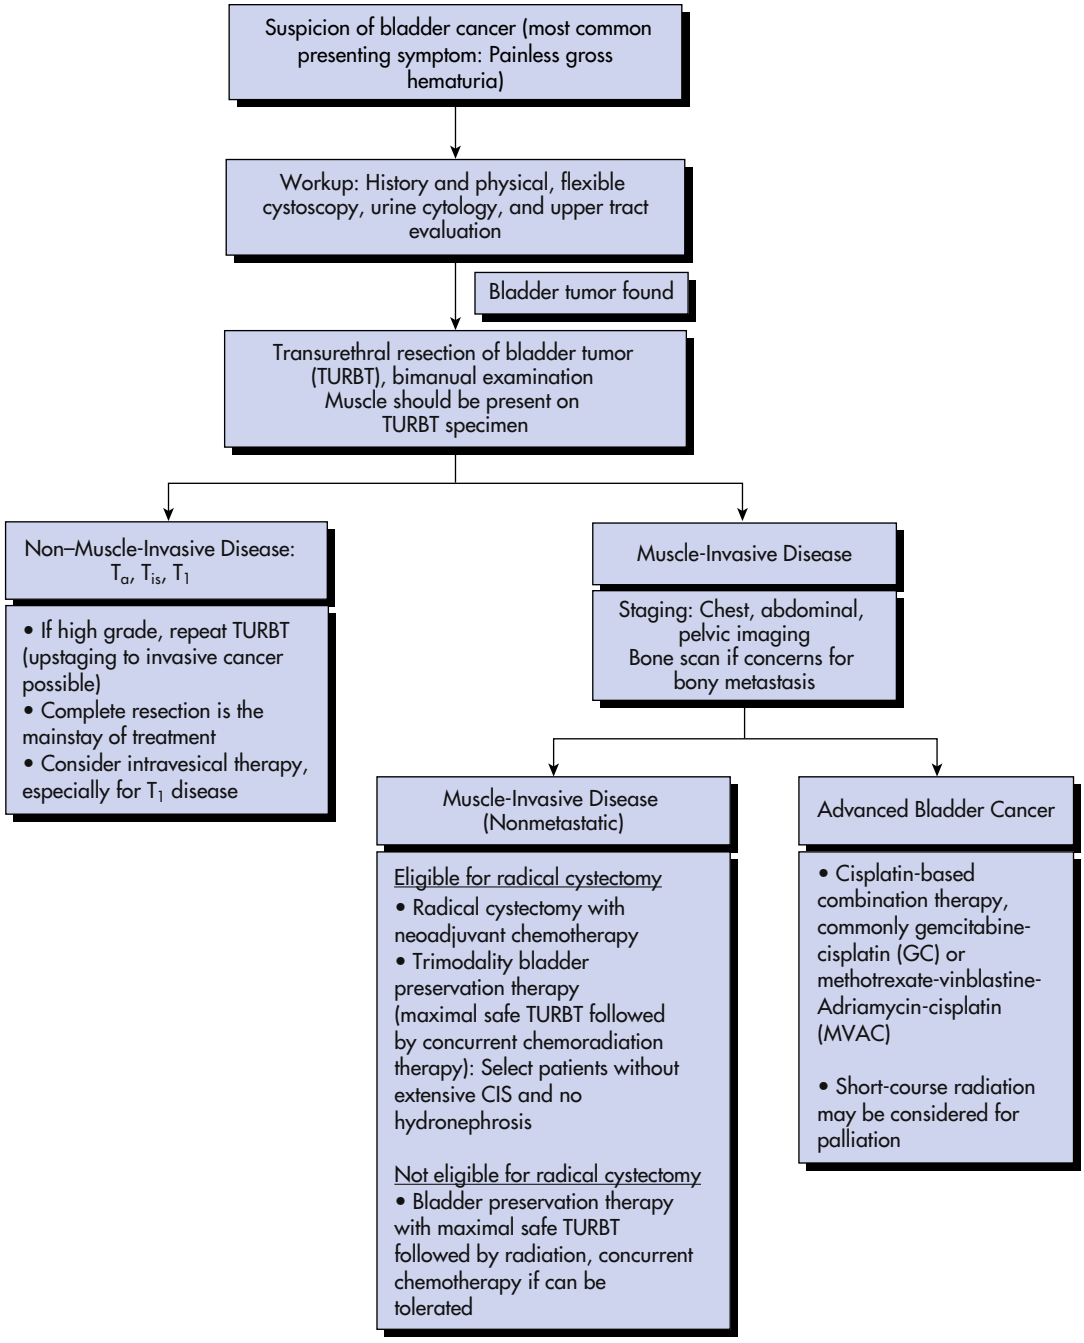

FIG. 1 Diagnostic and treatment algorithm for bladder cancer. *CIS,* Carcinoma in situ. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

BLADDER PRESERVATION APPROACHES: After cystectomy for muscle-invasive disease, 50% or more of the patients will develop metastases. Most patients develop metastases at distant sites; a third relapse locally. Bladder preservation management is offered in individuals who refuse surgery or who might not be suitable radical cystectomy patients. Bladder-sparing protocols include extensive TURBT or partial cystectomy with external-beam or interstitial radiotherapy and systemic chemotherapy. Radiotherapy as a single treatment modality is not effective. The best predictor of successful bladder preservation is a complete response after the combination of initial TURBT and neoadjuvant chemotherapy with stages T_2 to T_{3a}.

INDICATIONS FOR PARTIAL CYSTECTOMY:
- Tumor within a bladder diverticulum
- Solitary, primary, and muscle-invasive or high-grade lesion of a region of the bladder that allows complete excision with adequate surgical margins
- Inability to adequately resect tumor by TURBT alone because of size or location
- Tumor overlying a ureteral orifice requiring ureteral reimplantation
- Biopsy of a radiation-induced ulceration
- Palliation of severe local symptoms
- Patient refusal of urinary diversion
- Poor-risk patient who is not a diversion candidate

CONTRAINDICATIONS:
- Multiple tumors
- CIS
- Cellular atypia on biopsy
- Prostatic invasion
- Invasion of the trigone
- Inability to achieve adequate surgical margins
- Prior radiotherapy
- Inability to maintain adequate bladder volume after resection
- Evidence of extravesical tumor extension
- Poor surgical risk

BOX 1 American Urological Association Guideline Recommendations

For all index patients:
- Standard: Physicians should discuss with the patient the treatment options and the benefits and harms, including side effects, of intravesical treatment.

For a patient who presents with an abnormal growth on the urothelium but who has not yet been diagnosed with bladder cancer:
- Standard: If the patient does not have an established histologic diagnosis, a biopsy should be obtained for pathologic analysis.
- Standard: Under most circumstances, complete eradication of all visible tumors should be performed.
- Standard: If bladder cancer is confirmed, periodic surveillance cystoscopy should be performed.
- Option: An initial single dose of intravesical chemotherapy may be administered immediately postoperatively.

For a patient with small volume, low-grade T_a bladder cancer:
- Recommendation: An initial single dose of intravesical chemotherapy may be administered immediately postoperatively.

For a patient with multifocal and/or large volume, histologically confirmed, low-grade T_a or a patient with recurrent low-grade T_a bladder cancer:
- Recommendation: An induction course of intravesical therapy with bacillus Calmette-Guérin or mitomycin C is recommended for the treatment of these patients with the goal of preventing or delaying recurrence.
- Option: Maintenance bacillus Calmette-Guérin or mitomycin C may be considered.

For a patient with initial histologically confirmed high-grade T_a, T_1, and/or carcinoma in situ bladder cancer:
- Standard: For patients with lamina propria invasion (T_1) but without muscularis propria in the specimen, repeat resection should be performed prior to additional intravesical therapy.
- Recommendation: An induction course of bacillus Calmette-Guérin followed by maintenance therapy is recommended for treatment of these patients.
- Option: Cystectomy should be considered for initial therapy in select patients.

For a patient with high-grade T_a, T_1, and/or carcinoma in situ bladder cancer that has recurred after prior intravesical therapy:
- Standard: For patients with lamina propria invasion (T_1) but without muscularis propria in the specimen, repeat resection should be performed prior to additional intravesical therapy.
- Recommendation: Cystectomy should be considered as a therapeutic alternative for these patients.
- Option: Further intravesical therapy may be considered for these patients.

ACUTE GENERAL Rx

INDICATIONS FOR INTRAVESICAL CHEMOTHERAPY:
- High-grade tumor
- Tumor size <5 cm
- Multiple tumors
- Presence of CIS
- Positive urinary cytologic findings after a resection
- Incomplete tumor resection

Intravesical agents: Thiotepa, doxorubicin, mitomycin C, BCG, interferon, interleukin-2, and keyhole-limpet hemocyanin. Photodynamic therapy with hematoporphyrin derivatives has also been used.

INDICATIONS FOR CYSTECTOMY:
- Large tumors not amenable to complete TURBT
- High-grade tumor
- Multiple tumors with frequent recurrences
- Diffuse CIS not responsive to intravesical chemotherapy
- Prostatic urethra involvement
- Irritative bladder symptoms with upper tract deterioration
- Muscle-invasive disease
- Disease outside the bladder

SYSTEMIC THERAPY:
- Cisplatin-based chemotherapy is used concurrently with radiotherapy in bladder preservation or neoadjuvant therapy approaches for resectable cases.
- Combination chemotherapy regimens are used as perioperative (neoadjuvant and adjuvant) therapy for locally advanced disease in conjunction with bladder resection.
- In fit patients with metastatic cancers, combination cisplatin-based chemotherapy regimens are used as palliative therapy. The most effective combination regimens include MVAC (cisplatin, methotrexate, vinblastine, doxorubicin) and GC (gemcitabine, cisplatin), which provide palliation and modest survival benefit.
- In patients with metastatic cancers who are unfit to receive cisplatin-based chemotherapy regimens, the use of immune checkpoint inhibitors is the preferred therapy option. Available agents include the PD-1 inhibitors (nivolumab, pembrolizumab) and PDL-1 inhibitors (atezolizumab, durvalumab, avelumab). These are also used as salvage therapy in patients who have failed prior chemotherapy approaches.
- Alterations in the gene encoding fibroblast growth factor receptor (FGFR) are detected in 15% to 20% of cases of locally advanced or metastatic urothelial carcinoma. Erdafitinib, a tyrosine kinase inhibitor of FGFR1-4, has shown response rates of 40% in previously treated patients with FGFR alterations, and median survival was reported at approximately 14 mo.

RADIOTHERAPY: Conflicting reports suggest that superficial bladder cancer is more sensitive to radiotherapy. Only 20% to 30% of patients with invasive bladder cancer can be cured by external-beam radiation therapy alone. It is used in combination with surgery or with systemic agents to treat bladder cancer primarily in patients who are not surgical candidates or who refuse surgery. Combination chemotherapy (cisplatin) given concurrently with radiotherapy has shown significant improved locoregional control of bladder cancer in bladder-preservation strategies.

CHRONIC Rx

FOLLOW-UP RECOMMENDATIONS FOR SUPERFICIAL BLADDER CANCER:
- Cystoscopy, bladder barbotage, and bimanual examination every 3 mo for 2 yr, then every 6 mo for 2 yr, and annually thereafter.
- Upper tract studies are based on the risk of upper tract tumor development, generally every 2 to 5 yr.

PEARLS & CONSIDERATIONS

COMMENTS
- Useful prognostic parameters for bladder tumor recurrence and subsequent progression are tumor grade, tumor depth, multifocal tumors, frequency of recurrence, tumor size, CIS, lymphatic invasion, papillary or solid tumor configuration.
- Currently, the incidence of occupational bladder cancer seems to be increasing faster in women than in men. Workers with aromatic amine exposure have the highest incidence, whereas those exposed to polycyclic aromatic hydrocarbons and heavy metals have the greatest mortality.
- The 5-yr survival for bladder cancer is 76%; it ranges from 96% for in situ, 70% for localized, 35% for regional, and 5% for distant cancers.
- Box 1 describes the American Urological Association Guideline Recommendations for bladder cancer.

BASIC INFORMATION

DEFINITION

The International Continence Society defines bladder pain syndrome, otherwise known as interstitial cystitis (IC), as a clinical syndrome consisting of suprapubic pain related to bladder filling and accompanied by other symptoms, such as increased daytime and nighttime frequency in the absence of proven infection or other obvious pathology. The American Urological Association defines interstitial cystitis/bladder pain syndrome (IC/BPS) as an unpleasant sensation perceived to be related to the urinary bladder that is associated with lower urinary tract symptoms >6 wk duration, in the absence of infection or other unidentifiable causes.

SYNONYMS

Interstitial cystitis
Interstitial cystitis/bladder pain syndrome (IC/BPS)
Painful bladder syndrome
Tic douloureux of bladder

ICD-10CM CODES

N30.1	Interstitial cystitis (chronic)
N30.9	Cystitis, unspecified
N30.10	Interstitial cystitis (chronic) without hematuria
N30.11	Interstitial cystitis (chronic) with hematuria

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 21 cases per 100,000 women and four cases per 100,000 men annually

PREVALENCE:

- 197 per 100,000 women and 41 per 100,000 men in the U.S.
- Because the disease is substantially underdiagnosed, it may actually affect one in five women and one in 20 men.
- More than 81% of women diagnosed with chronic pelvic pain and up to 84% of men initially diagnosed with chronic prostatitis actually have IC.
- More than 90% of patients diagnosed with overactive bladder who do not respond to anticholinergics are subsequently diagnosed with IC.

PREDOMINANT SEX AND AGE:

- White women constitute 95% of patients with IC
- Female:male ratio of 5 to 10:1
- Most prevalent in fourth and fifth decades of life

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Urinary urgency, frequency (>8 in daytime), nocturia (>2 at night), and suprapubic pain are the most common symptoms
- Suprapubic pain is worse with bladder filling or urinating and relieved after emptying
- Dyspareunia
- Symptoms lasting longer than 6 mo
- Intensity of symptoms waxes and wanes
- Insidious onset and worsens to the final stage within 5 to 15 yr
- Exercise, stress, sexual activity, ejaculation, certain foods with high potassium and acids (beer, spices, bananas, tomatoes, chocolate, strawberries, artificial sweeteners, oranges, cranberries, caffeine), menstruation, prolonged sitting, and activation of allergies exacerbate the symptoms
- Often associated with irritable bowel syndrome, migraine, endometriosis, skin sensitivities, multiple drug allergies, other allergies, vulvodynia, fibromyalgia, chronic fatigue syndrome, systemic lupus erythematosus, and mood disorders
- Dysphoric mood
- Lower abdominal tenderness
- Tender prostate in digital rectal examination
- Levator ani tenderness in female
- Tenderness of anterior vaginal wall/bladder neck in female

ETIOLOGY

Unknown. Fig. 1 illustrates a hypothesis for etiologic cascade of painful bladder syndrome/interstitial cystitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Chronic pelvic pain
- Overactive bladder
- Recurrent urinary tract infection
- Endometriosis
- Pelvic adhesions
- Vulvar vestibulitis
- Vulvodynia
- Urethral pain syndrome
- Chronic nonbacterial prostatitis
- Frequent vaginitis
- Benign prostatic hyperplasia

WORKUP

- IC can be considered a diagnosis of exclusion when no known cause of painful bladder can be identified.
- There is no definite diagnostic test.

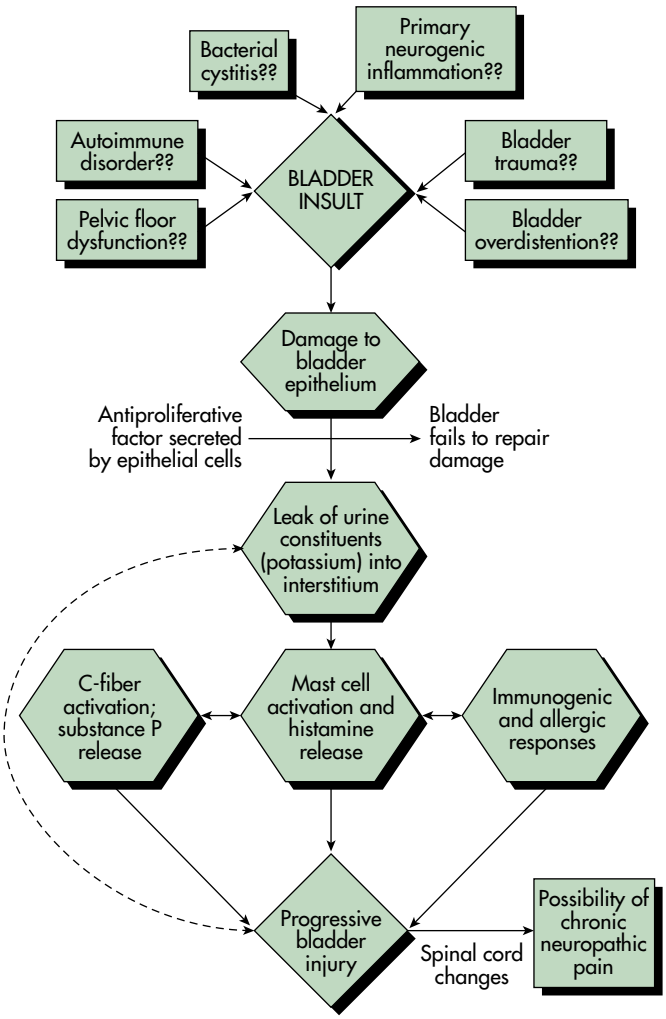

FIG. 1 Hypothesis for etiologic cascade of painful bladder syndrome/interstitial cystitis. (From Wein AJ: Painful bladder syndrome/interstitial cystitis and related disorders. In Wein AJ et al [eds]: *Campbell-Walsh urology*, ed 11, Philadelphia, 2007, Elsevier.)

- Validated questionnaires such as Pelvic Pain and Urgency/Frequency scale (PUF), O'Leary-Sant symptoms and problem index, and Wisconsin IC scale. PUF is the most commonly used.
- Voiding diary shows low-volume (<100 ml) and high-frequency voiding pattern.
- National Institute of Diabetes and Diseases of the Kidney diagnostic criteria misses 60% of IC patients and is not clinically used anymore.
- Anesthetic bladder challenge: With this test the symptoms dissipate on instillation of an anesthetic cocktail into the bladder.
- Cystoscopy and hydrodistention under general anesthesia may show terminal hematuria (Fig. E2), glomerulation, Hunner ulcers (Fig. E3), and small bladder capacity of less than 350 ml. Cystoscopy and/or urodynamic testing should be considered when the diagnosis is in doubt, but the tests are not necessary to confirm an IC/BPS diagnosis in uncomplicated cases.
- Bladder biopsy is not essential for diagnosis of IC.
- Parson potassium sensitivity test (PST).
- Urodynamics are unnecessary in diagnosis of IC.

LABORATORY TESTS

- Urine analysis and culture.
- Urine cytology should be performed if microscopic or gross hematuria is present, or with other risk factors such as smoking, age >40 yr, and other bladder cancer risk factors.
- Culture of sexually transmitted diseases if clinically indicated. Nonbacteriuric patients with pyuria should be screened for *Chlamydia.*
- Urine biomarkers (e.g., antiproliferative factor) are promising but not ready for clinical use.

IMAGING STUDIES

CT or ultrasound of abdomen and pelvis may be considered to rule out other pathology.

Rx TREATMENT

- There is no consensus for optimal management.
- There is no cure for this disease.

NONPHARMACOLOGIC THERAPY

- Avoidance of activities associated with flare-ups
- Avoidance of smoking
- Dietary restriction, avoiding common irritants (e.g., coffee, citrus fruits)
- Physical therapy
- Exercise
- Behavioral therapy
- Bladder retraining
- Biofeedback
- Warm sitz bath, ice, heating pad
- Thiele massage (transrectal and transvaginal manual therapy of pelvic floor muscle) in presence of pelvic floor muscle tenderness and spasm
- Hydrodistention only gives temporary relief, so it is not commonly used anymore

ACUTE AND CHRONIC Rx

- A course of empiric antibiotics if not tried yet. Long-term oral antibiotics are not recommended.
- Oral therapy is tried first.
- Pentosan polysulfate sodium (Elmiron) is the only FDA-approved and most effective oral therapy.
- Most treatment takes 3 to 6 mo before maximum benefit is seen.
- Adjunct oral therapy includes tricyclic antidepressants (amitriptyline), cimetidine, antihistaminics (hydroxyzine, montelukast), neuroleptics (gabapentin, topiramate), analgesics (NSAIDs, opioid analgesics), and occasionally antimuscarinics.
- Oral therapies can be used in combination.
- Antihistaminics are preferred for patients with an allergy history or those who show mast cells in bladder biopsy.
- Oral prednisone is used in presence of Hunner ulcers.
- Other drugs rarely used for IC are cyclosporin A, interleukin-10, imatinib, methotrexate, suplatast, misoprostol, and quercetin.
- Growth factor inhibitors, gene therapy, RDP 58, and vitamin B_3 analogue (BXL 628) may represent future therapies.
- Intravesical treatment is used when oral medications fail, for acute flare-ups, or before the oral medications take full effect.
- Dimethyl sulfoxide (DMSO), heparin, lidocaine, hyaluronic acid, capsaicin, botulinum toxin A, chondroitin sulfate, steroids, and Elmiron are drugs used for intravesical treatment.
- DMSO is the only FDA-approved intravesical treatment.
- DMSO is used less often now because of its side effects, specifically a garlic-like odor or taste on breath or skin that lasts 72 hr after treatment.
- Intravesical therapy typically involves mixture of heparin or Elmiron with lidocaine and sodium bicarbonate.
- Silver nitrate and clorpactin have fallen out of favor.

SURGERY

- Major surgical intervention is not the mainstay of treatment.
- Patients whose condition is extreme and who are miserable may consider surgery if medications fail.
- Sacral neuromodulation (InterStim) is the current preferred surgical intervention.
- Laser ablation, fulguration, or resection is offered when Hunner ulcers are seen in cystoscopy.
- Augmentation cystoplasty is not recommended.
- Cystourethrectomy with urinary diversion is rarely done.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Transcutaneous electric nerve stimulation
- Intravaginal electric nerve stimulation
- Acupuncture
- Urinary chelating agents such as Polycitra-K crystals, Urocit-K
- Prelief, an over-the-counter food additive
- Herbal remedies such as Algonot Plus, CystoProtek, Cysta-Q, aloe vera

DISPOSITION

Voiding diary and symptom questionnaire are helpful to monitor response to treatment.

REFERRAL

- Urologist
- Pain specialist
- Physical therapist

! PEARLS & CONSIDERATIONS

COMMENTS

- On average, these patients see five physicians and endure irritating voiding symptoms for 5 yr before the disease is identified.
- Besides symptom questionnaire and urine analysis, all other diagnostic tests are optional.
- PST is well tolerated.
- Negative cystoscopy does not rule out IC.

PREVENTION

Early identification and timely intervention improve patient outcome.

PATIENT & FAMILY EDUCATION

- IC support groups
- Interstitial Cystitis Association
- Interstitial Cystitis Network

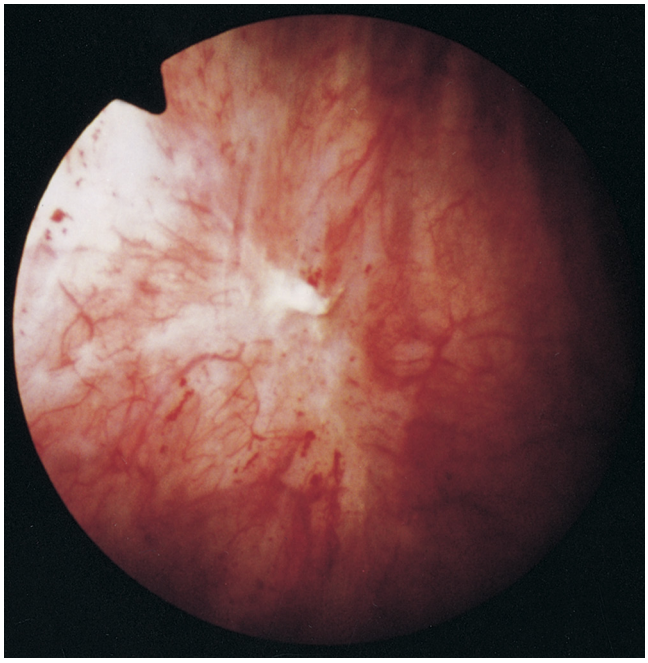

FIG. E3 Typical appearance of Hunner ulcer in a patient with bladder pain syndrome before bladder distention. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

Blastomycosis

BASIC INFORMATION

DEFINITION

Blastomycosis is a systemic pyogranulomatous disease caused by a dimorphic fungus, *Blastomyces dermatitidis.* Since 2013, another variant, *Blastomyces gilchristii*, has been described in the literature.

ICD-10CM CODES

B40.9	Blastomycosis, unspecified
B40.0	Acute pulmonary blastomycosis
B40.1	Chronic pulmonary blastomycosis
B40.2	Pulmonary blastomycosis, unspecified
B40.3	Cutaneous blastomycosis
B40.7	Disseminated blastomycosis
B40.89	Other forms of blastomycosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE & PREVALENCE:

- Most patients reside primarily in North America in the southeastern and south central U.S., especially those bordering the Mississippi and Ohio River valleys, the Midwestern U.S., and Canadian provinces bordering the Great Lakes.
- Point source outbreaks usually occur.
- Rare cases reported outside the U.S.

RISK FACTORS:

- Widely disseminated disease is most common in immunocompromised hosts, especially those with acquired immunodeficiency syndrome (AIDS).
- Initial infections result from inhalation of conidia into the lungs, although primary cutaneous blastomycosis has been reported after dog bites.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute infection: <50% symptomatic, median incubation 30 to 45 days. Symptoms are nonspecific: Mimic influenza or bacterial infection with abrupt onset of myalgias, arthralgias, chills, and fever; transient pleuritic pain, cough that is initially nonproductive. Resolution within 4 wk is usual.
- Chronic or recurrent infection: Indolent, progressive; includes pulmonary or extrapulmonary disease.

PULMONARY MANIFESTATIONS: Symptoms and signs of chronic pneumonia: Productive cough, hemoptysis, pleuritic chest pain, weight loss, low-grade pyrexia

- *B. gilchristii* infection has been linked to fatal acute respiratory distress syndrome in adults.

EXTRAPULMONARY MANIFESTATIONS:

- Cutaneous: Most common; may occur with or without pulmonary disease (Fig. E1). Two different lesions:
  1. *Verrucous:* Beginning as a small papulopustular lesion on exposed body areas that may develop into an eschar with peripheral microabscesses (Fig. E2).
  2. *Ulcerative:* Subcutaneous nodules (cold abscesses) and rarely cutaneous inoculation blastomycosis may occur.
- Bone and joint: 10% to 50% have osteolytic lesions (Fig. E3); affects long bones, vertebrae, and ribs; lesions may present with contiguous soft tissue abscess or draining sinus that spreads to a joint, resulting in pyarthrosis.
- Genitourinary: 10% to 30%; prostatic involvement is most common and may present as obstruction; epididymis and testes may also be affected.
- Central nervous system: 5% normal host; 40% AIDS patients; meningitis and abscess formation.

ETIOLOGY

B. dermatitidis exists in warm, moist soil that is rich in organic material. When these microfoci are disturbed, the aerosolized spores or conidia are inhaled into the lungs. Disease at other sites is a result of dissemination from the initial pulmonary infection; the latter may be acute or chronic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

PULMONARY INFECTION:

- Bacterial pneumonia
- Histoplasmosis
- Coccidioidomycosis
- Tuberculosis
- Bronchogenic carcinoma

CUTANEOUS INFECTION:

- Bromoderma
- Pyoderma gangrenosum
- *Mycobacterium marinum* infection
- Squamous cell carcinoma
- Giant keratoacanthoma

WORKUP

- Physical examination and laboratory data
- Definitive diagnosis established by culture or by visualization of organisms by fungal stains
- Antibody tests lack sensitivity

LABORATORY TESTS

- Presumptive diagnosis can be made by visualizing the distinctive yeast forms in clinical specimens
- Culture: On Sabouraud medium or more enriched media
  1. Aspirated material from abscesses
  2. Skin scrapings
  3. Prostatic secretions (urine culture with prostatic massage)

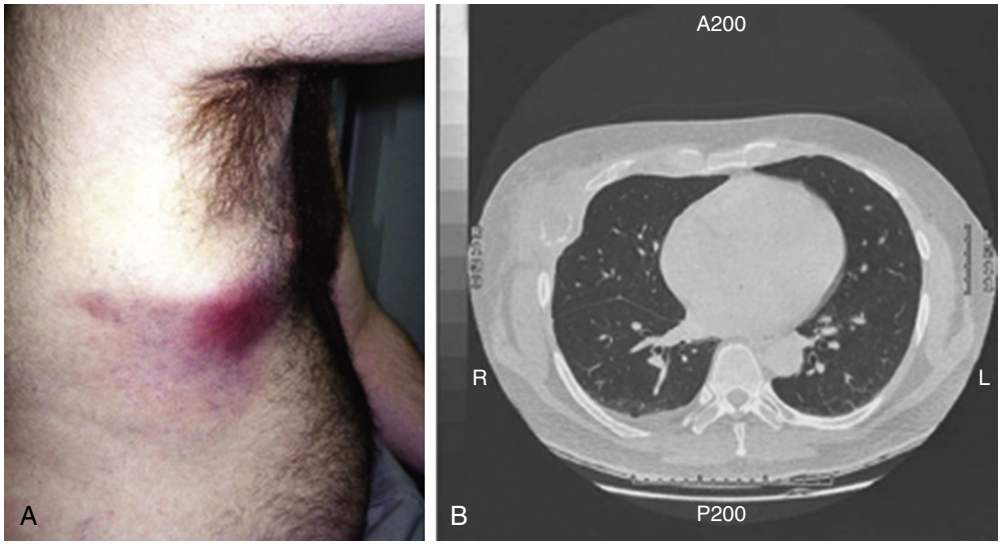

FIG. E1 A, Blastomycosis osteomyelitis of a rib and chest wall. **B,** Computed tomography scan appearance. Primary infection in the blood may spread to the skeleton. (From Firestein GS et al: *Kelley's textbook of rheumatology*, ed 9, Philadelphia, 2013, WB Saunders, Elsevier.)

FIG. E2 The typical verrucous skin lesion of blastomycosis on the cheek. Note the circumscribed edges. (From Mandell GL et al: *Principles and practice of infectious diseases,* ed 6, Philadelphia, 2005, Churchill Livingstone.)

- Direct examination of specimens
  1. Wet preparation with 10% KOH (Fig. E4)
  2. Histopathology: Typically demonstrates pyogranulomas; yeast identification requires special stains
- A commercial test for *Blastomyces* antigen in specimens of urine, blood, and other fluids is available
- Serologic tests: A negative test result cannot exclude blastomycosis, and a positive titer should not be an indication to start treatment; therefore, current serologic assays serve no role

IMAGING STUDIES

In chronic disease, chest radiographic findings are nonspecific, but lobar or segmental alveolar infiltrates, especially of the upper lobes, are most common and may progress to cavitation.

Rx TREATMENT

- Treatment remains controversial for acute pulmonary blastomycosis. Generally, all immunocompromised patients and patients with moderate to severe pneumonia or disseminated infection require therapy.
- Because the acute form may be benign and self-limited, some patients may be closely observed.
- Resolution of chronic blastomycosis without antifungal therapy is uncommon, and untreated blastomycosis has been associated with mortality rates approaching 60%.

NON–CENTRAL NERVOUS SYSTEM BLASTOMYCOSIS

Moderately severe to severe:

- Liposomal amphotericin B (L-AmB) 3 to 5 mg/kg/day or L-AmB 0.7 to 1 mg/kg/day × 1 to 2 wk or until clinical response, then itraconazole oral solution 2.5 mg/kg po tid for 3 days, then once daily or bid for 6 to 12 mo

Mild to moderate:

- Itraconazole 200 mg PO tid for 3 days and then once or bid for 6 to 12 mo

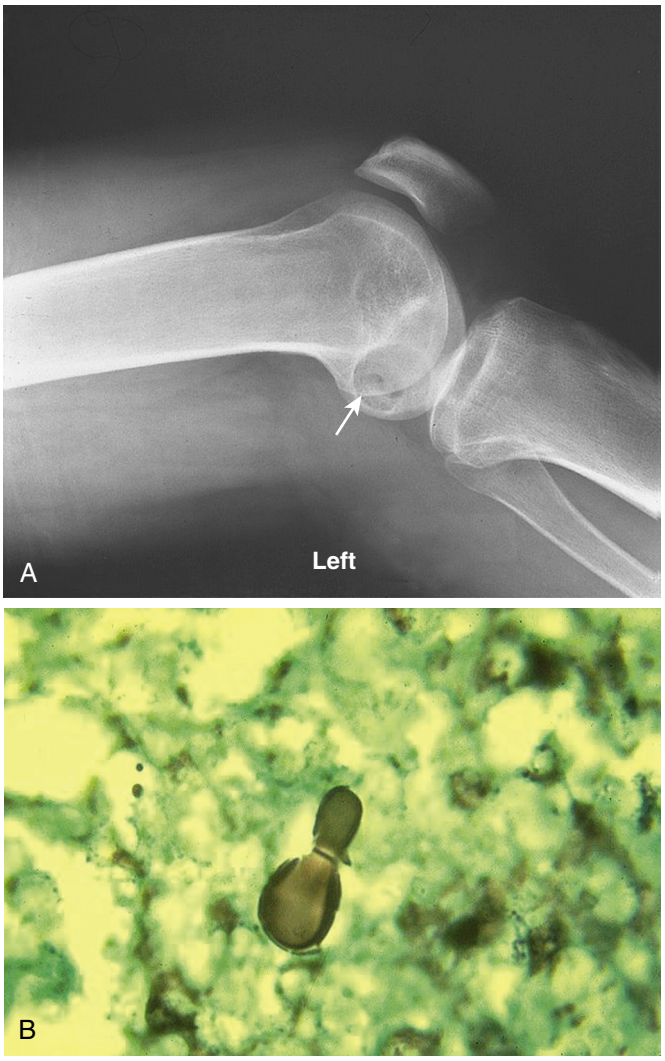

FIG. E3 Blastomycosis joint infection. A, Radiographs commonly show punched-out bone lesions *(arrow)*. **B,** Synovial histology shows epithelioid granulomas with budding yeast forms. (From Firestein GS et al: *Kelley's textbook of rheumatology*, ed 9, Philadelphia, 2013, WB Saunders, Elsevier.)

Alternative regimens:

- Posaconazole delayed-release tabs 300 mg PO bid for 2 doses and then 300 mg PO daily; suspension 200 mg 4x daily and then 400 mg po bid after stabilization of disease or 300 mg IV over 90 min bid for 1 day and then 300 mg IV daily
- Voriconazole 4 mg/kg po bid
- Isavuconazonium sulfate 372 mg po/IV tid for 6 doses then 372 mg po/IV daily
- Fluconazole 400 to 800 mg PO once a day (less effective than Itraconazole)

CENTRAL NERVOUS SYSTEM BLASTOMYCOSIS

Liposomal amphotericin B at a dosage of 5 mg/kg/day over 4 to 6 wk, followed by either fluconazole 800 mg/day or voriconazole 6 mg/kg bid for two doses and then 4 mg/kg bid for at least 12 mo and until resolution of cerebrospinal fluid abnormalities

NOTE:

- Lifelong suppressive therapy with oral itraconazole 200 mg/day may be required, especially in immunocompromised individuals.

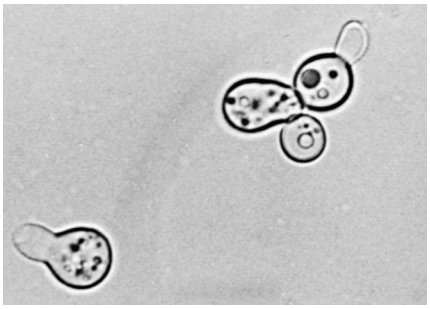

FIG. E4 Yeast cells of *Blastomyces dermatitidis* in wet smear (×1000). (From Mandell GL et al: *Principles and practice of infectious diseases,* ed 6, Philadelphia, 2005, Churchill Livingstone.)

- Serum itraconazole levels should be determined in all patients after they have received treatment with this agent for 2 wk.
- Surgery may be indicated for drainage of large abscesses.

DISPOSITION

- Before antifungal therapy, the disease had a progressive course with eventual extrapulmonary disease and a mortality rate approaching 60%.
- Relapse rate for patients treated with AmB is 5%; relapse is more common in AIDS patients.

PEARLS & CONSIDERATIONS

- *Blastomyces dermatitidis* may mimic other diseases.
- Colonization does not occur as with *Candida* and *Aspergillus* species.

BASIC INFORMATION

DEFINITION

Blepharitis is a chronic inflammation of the eyelid margins that is often refractory to treatment with infectious and noninfectious etiologies.

SYNONYMS

Eyelid infection or inflammation
Eczema of the eyelids
Dermatoblepharitis
Angular blepharitis

ICD-10CM CODES

H01.009	Unspecified blepharitis unspecified eye, unspecified eyelid
H01.019	Ulcerative blepharitis unspecified eye, unspecified eyelid
H01.029	Squamous blepharitis unspecified eye, unspecified eyelid

EPIDEMIOLOGY & DEMOGRAPHICS

- Common in children, particularly those with atopic dermatitis and eczema.
- Adults with seborrhea involving the eyelids.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Common symptoms: Red eyes, burning sensation, excessive tearing, blurred vision, pruritic eyelids.
- Chronically infected lids are usually diffusely erythematous with collarettes (fibrin exudate) at the base of the lashes.
- Lid margins thicken over time, with associated loss of eyelashes (madarosis), misdirected growth of lashes (trichiasis), and overflow or inspissation of the meibomian glands (Fig. E1).
- Associated conjunctivitis with erythema and edema but no discharge.
- Chalazion: Chronic sterile inflammation of an oil gland of the eyelid.
- Superficial punctate erosions of the inferior corneal epithelium are common.
- More severe findings, such as corneal pannus, ulcerative keratitis, or lid ectropion, are less common.

ETIOLOGY

Multiple: Bacterial and nonbacterial causes:

- Staphylococcal infection most common but streptococcal, Moraxella, and other bacterial infections; viral infections (e.g., herpes simplex, herpes zoster, *Molluscum contagiosum*); and a number of ecoparasites (Fig. E2), including pediculosis, may cause blepharitis
- Seborrheic dermatitis
- Rosacea
- Dry eye (keratoconjunctivitis sicca): Decrease in tear volume
- Meibomian gland dysfunction
- Contact lens intolerance
- Two categories of blepharitis (Table E1):
  1. Anterior blepharitis, most often associated with staphylococcal infection
  2. Posterior blepharitis, associated with meibomian gland dysfunction and seborrheic dermatitis or rosacea

NOTE: Blepharitis patients have normal skin microflora in greater amounts (mostly *S. epidermidis* and *Propionibacterium acnes*). (*S. aureus* and *S. epidermidis* can be cultured in 10% to 35% and 90% to 95% of healthy persons, respectively.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Keratoconjunctivitis sicca
- Eyelid malignancies

FIG. E1 Chronic posterior blepharitis. TABLE E1 Summary of Characteristics of Chronic Blepharitis

Feature	Anterior Blepharitis	Staphylococcal	Seborrhoeic	Posterior Blepharitis
Lashes	Deposit	Hard	Soft	
	Loss	++	+	
	Distorted or trichiasis	++	+	
Lid margin	Ulceration	+		
	Notching	+		++
Cyst	Hordeolum	++		
	Meibomian			++
Conjunctiva	Phlyctenule	+		
Tear film	Foaming			++
	Dry eye	+	+	++
Cornea	Punctate erosions	+	+	++
	Vascularization	+	+	++
	Infiltrates	+	+	++
Commonly associated skin disease		Atopic dermatitis	Seborrhoeic dermatitis	Acne rosacea

From Bowling B: *Kanski's clinical ophthalmology, a systemic approach*, ed 8, Philadelphia, 2016, Elsevier.

- Herpes simplex blepharitis
- Molluscum contagiosum
- Phthiriasis palpebrarum
- *Phthirus pubis* (pubic lice)
- *Demodex folliculorum* (transparent mites)
- Allergic blepharitis

WORKUP

Scrapings of the eyelids to show polymorphonuclear leukocytes and gram-positive cocci

LABORATORY TESTS

Eyelid cultures and antibiotic sensitivity testing (usually not done unless patient fails to respond to initial treatment regimen)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Alkaline soaps may be beneficial; alcohol and some detergents remove surface lipids and microflora.
- Hot compresses applied to closed lids for 5 to 10 min: Heat loosens debris from lid margins and increases meibomian gland fluidity.
- Firm massage of the lid margins to enhance the flow of secretions from glands, followed by cleansing of the lids with cotton-tipped applicators dipped in a 50:50 mixture of baby shampoo and water.
- Lashes and lid margins scrubbed vigorously while the eyelids are closed, followed by thorough rinsing.
- Following local massage and cleansing, the mainstay of treatment is application of topical antibiotic ointment to the eyelid margins.
  1. Most effective topical antibiotics include bacitracin, erythromycin or 1% azithromycin solution, aminoglycoside and fluoroquinolone ophthalmic ointments.
  2. Ointment is applied 1 to 4 times daily, depending on the severity, for 1 to 2 wk, followed by once daily, at bedtime, for another 4 to 8 wk until all signs of inflammation have disappeared.
- Oral antibiotics: Long-term use of doxycycline or tetracycline in a tapering dose may be helpful in severe cases for patients older than 12 yr of age.
- Topical glucocorticoids: Short-term use in acute exacerbations of blepharitis.
- For patients with rosacea: Tetracycline 250 mg orally 4 times daily or doxycycline 100 mg orally bid along with local treatment for several months.
- Recalcitrant cases with antibiotic resistance:
  1. Vancomycin eye drops 1%
  2. Ciprofloxacin or ofloxacin eye drops

CHRONIC Rx

- By definition, this is a chronic condition for which there is frequently no cure.
- Some newer agents being evaluated are topical cyclosporine 0.05% eye drops, thermal pulsation systems to break up material in meibomian glands, topical metronidazole and topical tacrolimus, and tear lipid substitutes.

DISPOSITION

This condition may be refractory to treatment.

REFERRAL

To an ophthalmologist if patient fails to respond to local therapy

BASIC INFORMATION

DEFINITION

Blepharospasm (BSP) is a movement disorder characterized by hyperactivity of the orbicularis oculi and other muscles around the eyes.

SYNONYMS

BSP
Orbicularis oculi spasms
Focal dystonia

ICD 10-CM CODE
G24.5 Blepharospasm

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Not applicable.
PEAK INCIDENCE: Not applicable.
PREVALENCE: Prevalence is between 20 and 133 cases per million depending on geographic area.
PREDOMINANT SEX AND AGE: Female preference, peak age at onset between the fifth and seventh decade.
GENETICS: Predominantly a sporadic disorder, however 25% of patients have one or more family members affected by dystonia. No specific genetic association specific to BSP is known.
RISK FACTORS: Risk of primary BSP increases with diseases of the anterior segment of the eye and preceding head trauma. Risk of secondary BSP increases with focal lesions in multiple brain regions, comorbid Parkinson disease, tardive dyskinesia, or conditions associated with eyelid weakness such as facial palsy and myasthenia.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Motor manifestations include orbicularis oculi (OO) spasms (Fig. E1), apraxia of eyelid opening, increased blinking rate, and dystonia at other body sites (most commonly oromandibular and cervical regions).
- OO spasms are stereotyped, bilateral, and synchronous. Spasms may be brief or sustained, and may induce narrowing or closure of the eyelids.
- Apraxia of eyelid opening is transient failure to voluntarily reopen the eyes without an apparent spasm of the OO muscle and despite sustained frontalis muscle contraction.
- Nonmotor manifestations include the presence of a so-called "sensory trick" (certain actions involving gentle stimulation to the face alleviate symptoms and allow patients with BSP to keep eyes open, e.g., light touch to certain areas of the face, wearing tinted lenses, talking, singing, or chewing/eating); other sensory symptoms (burning sensation and grittiness in the eye, dry eye, and photophobia); psychiatric disturbances (depression and obsessive/compulsive symptoms); sleep abnormalities, and cognitive dysfunction.

ETIOLOGY

- Primary BSP is predominantly sporadic, although up to 25% of patients have one or more family members with dystonia. Several genes are associated with adult-onset dystonia, though none have been associated with pure BSP.
- Secondary BSP is associated with several different focal lesions of the brain (thalamus, basal ganglia, lower brain stem, cerebellum, midbrain, and cortex) or may be associated with other movement disorders including PD, TD, facial palsy, or myasthenia.
- A proposed mechanism involves loss of striatal dopamine leading to reduced tonic inhibition of trigeminal reflex circuits combined with weakening of lid closure by the OO muscle. This leads to an adaptive increase in activity of trigeminal sensory-motor blink circuits.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pure apraxia of eyelid opening, a common feature of lesions of the nondominant parietal lobe (among other regions)
- Bell palsy (unilateral facial weakness involving both the upper and lower face due to lower-motor-neuron facial nerve palsy; etiology may be viral, inflammatory, autoimmune, or ischemic)
- Eyelid myokymia (typically unilateral, spontaneous, fine fascicular contractions of the lower orbicularis oculi without atrophy or weakness)
- Hemifacial spasm (brief clonic movements of OO typically spreading to other facial regions, often associated with chronic irritation of the facial nerve or nucleus)
- Dry eye, or conjunctivitis/keratitis with frequent blinking
- Myasthenia gravis with eyelid ptosis

WORKUP

BSP is a clinical diagnosis that relies on thorough neuropsychiatric and ophthalmologic evaluation.

LABORATORY TESTS

No tests are diagnostic. However, certain findings on electromyography (evaluation of blink reflex excitability recovery curve) present in dystonia and BSP, but not in psychogenic BSP, may reinforce clinical suspicion.

IMAGING STUDIES

Standard brain imaging has not consistently demonstrated clinical utility for BSP.

TREATMENT

ACUTE GENERAL Rx

- Botulinum neurotoxin type A is first-line treatment for BSP. Side effects such as transient ptosis, blurred vision, and diplopia are uncommon and tend to improve spontaneously within weeks.
- Modest improvement has come with anticholinergics (e.g., trihexyphenidyl), benzodiazepines, baclofen, and tetrabenazine. However, side effects may be too problematic.

CHRONIC Rx

Long-term efficacy of Botulinum neurotoxin type A treatment in BSP has been documented. However, this has not led to significant improvements upon quality of life, indicating non-motor manifestations of BSP require individual attention. More literature is needed in this regard.

REFERRAL

Movement disorder specialist consultation is common.

Body Dysmorphic Disorder (PTG)

BASIC INFORMATION

DEFINITION

Body dysmorphic disorder (BDD) is classified as an obsessive-compulsive and related disorder. It is characterized by preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear only slight to others, as well as repetitive behaviors (e.g., excessive grooming, mirror checking, skin picking, reassurance seeking) in response to the appearance concerns. The preoccupations cause clinically significant distress or impairment in social, occupational, or other important areas of functioning (usually both). The preoccupations are not better explained by concerns with body fat or weight in a person whose symptoms meet diagnostic criteria for an eating disorder.

SYNONYMS

Dysmorphophobia
BDD

ICD-10CM CODES
F45.22 Body dysmorphic disorder
DSM-5 CODE
300.50

EPIDEMIOLOGY & DEMOGRAPHICS

- Affects 1.7% to 2.9% of the general population (in nationwide epidemiologic studies)
- Prevalence among general cosmetic surgery patients is 13% to 15%
- Weighted prevalence in rhinoplasty surgery settings is 20.1%
- Weighted prevalence among dermatology outpatients is 11.3%
- Slightly higher prevalence among females (but not in cosmetic surgery or dermatology settings)
- Onset most commonly in early adolescence (two thirds have onset before age 18)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Excessive preoccupation (obsession) with one or more perceived defects in appearance that are not observable or appear only slight to others. Patients believe they look abnormal, ugly, unattractive, or deformed, whereas in reality they look normal. Any part of the body may be a focus of concern; skin (e.g., perceived acne or scarring), hair (e.g., perceived thinning or excessive body or facial hair), and nose (e.g., size or shape) concerns are most common. Muscle dysmorphia is a form of BDD that occurs primarily in men and focuses on excessive concern that one's body build is too small or is insufficiently muscular. Most patients are preoccupied with multiple body areas.
- The body areas with which the patient is concerned appear physically normal; if a physical defect is present, it is slight, and the patient's reaction to it is excessive.
- Most patients have poor insight (i.e., are mostly convinced) or absent insight (i.e., delusional beliefs; are completely convinced) regarding the accuracy of their beliefs about the appearance of the perceived defects.
- At some point during the course of the disorder, all patients engage in repetitive behaviors such as frequent mirror checking, excessive grooming, skin picking to try to fix perceived skin flaws, reassurance seeking, and repeatedly measuring or feeling the perceived defect. The intent of these behaviors is to check, try to improve, or gain reassurance about the appearance of the perceived flaws. Nearly all patients attempt to camouflage or hide the perceived defects—e.g., with makeup, a hat, hair, or body position.
- Nearly all experience impairment in psychosocial functioning and quality of life as a result of their appearance concerns; impairment is usually substantial.
- Suicidal ideation, suicide attempts, and completed suicide appear common.
- Commonly co-occurring mental disorders are major depressive disorder, substance use disorders (including abuse of anabolic androgenic steroids in muscle dysmorphia), social anxiety disorder, obsessive-compulsive disorder (OCD), and personality disorder.

ETIOLOGY

Likely multifactorial, with both genetic and environmental risk factors (e.g., teasing). Has shared genetic vulnerability with obsessive-compulsive disorder plus BDD-specific genetic influences. Neuropsychological and fMRI studies indicate abnormalities in visual processing consisting of excessive focus on details rather than on larger global and configural elements of visual stimuli (with some similarities to anorexia nervosa). Information processing deficits and biases also characterize BDD, which may also play a role in the disorder's development and/or maintenance.

DIAGNOSIS

Psychiatric interview: Ask:

- Are you very worried about your appearance in any way? *OR:* Are you unhappy with how you look?
- Does this concern with your appearance preoccupy you? If you add up all the time you spend each day thinking about your appearance, how much time would you estimate it takes (at least an hour a day)?
- How much distress does this concern cause you?
- What effect does this concern have on your life?
- Is there anything you feel an urge to do over and over again in response to your appearance concerns? (Give examples, such as mirror checking, comparing with others, skin picking to remove perceived skin flaws)
- Determine that the perceived appearance defects are actually nonexistent or only slight.

DIFFERENTIAL DIAGNOSIS

- Often undiagnosed because of patient's reluctance to divulge symptoms due to shame and fear of being misunderstood (e.g., considered vain)
- OCD
- Eating disorder
- Social anxiety disorder
- Major depressive disorder

WORKUP

Clinical evaluation focused on BDD symptoms and associated impairment in functioning.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cognitive behavioral therapy (CBT) with a focus on cognitive restructuring, exposure, perceptual retraining, and response (ritual) prevention; CBT must be specifically tailored to BDD's unique symptoms.
- Do not try to talk patients out of their concern; it is ineffective.
- Avoid cosmetic procedures; a majority of patients with BDD receive them, but such treatments do not appear effective for BDD. Dissatisfied patients may sue or even become violent toward the treating clinician.

CHRONIC Rx

- Serotonin reuptake inhibitors (SRIs) are medication of choice both acutely and chronically; high doses (similar to those for OCD) often needed
- Other agents (e.g., neuroleptics, tricyclic antidepressants other than clomipramine) do not appear as beneficial, although limited evidence suggests that atypical neuroleptics and buspirone may be helpful as SRI augmentation agents
- CBT tailored specifically to BDD is recommended, with an SRI if BDD symptoms are moderate to severe, the patient is suicidal because of BDD symptoms, or comorbidity is present that may benefit from an SRI
- Support groups if available
- More intensive BDD-focused treatment (e.g., intensive outpatient, residential treatment) if outpatient care is insufficient

DISPOSITION

- Untreated BDD tends to be chronic and can lead to social isolation; school dropout; loss of employment; major depression; abuse of drugs or alcohol; unnecessary surgery, dermatologic treatment, or other cosmetic treatment; and suicide.
- With correct diagnosis and treatment, a majority improve.

PEARLS & CONSIDERATIONS

- In clinical settings, approximately three quarters have lifetime co-occurring major depressive disorder; suicidal ideation is common.

- Reassurance that the patient looks normal is rarely helpful.
- Patients often have an unrealistic expectation of improvement with plastic surgery, dermatologic treatment, and other cosmetic procedures; these treatments do not appear to be effective.
- All patients should be screened and monitored for suicidality.

PATIENT/FAMILY EDUCATION

- Family support and encouragement of appropriate treatment is important.

Bone Tumor, Primary Malignant (ALG) (PTG)

BASIC INFORMATION

DEFINITION

Primary malignant bone tumors are invasive and anaplastic and have the ability to metastasize. These neoplasms can arise from the marrow (myeloma), but may also develop from bone, cartilage, fat, and fibrous tissues (Fig. E1). Leukemia and lymphoma are excluded from this discussion.

FIBROSARCOMA AND LIPOSARCOMA: They are extremely rare and similar to tumors arising in soft tissue.

OSTEOSARCOMA: A rare primary malignant tumor of bone characterized by malignant tumor cells that produce osteoid or bone. Several variants have been described: Parosteal sarcoma, periosteal sarcoma, multicentric, and telangiectatic forms.

CHONDROSARCOMA: A malignant cartilage tumor that may develop primarily or secondarily from transformation of a benign osteocartilaginous exostosis or enchondroma.

EWING SARCOMA: A malignant tumor of the bone or soft tissues characterized by the presence of small, round, blue cells on immunohistochemical evaluation.

MULTIPLE MYELOMA: A neoplastic proliferation of plasma cells in the bone marrow.

SYNONYMS

Multiple myeloma:
- Plasma cell myeloma
- Plasmacytoma

ICD-10CM CODES

C41.9	Malignant neoplasm of bone and articular cartilage, unspecified
C40.00	Malignant neoplasm of scapula and long bones of unspecified upper limb
C40.01	Malignant neoplasm of scapula and long bones of right upper limb
C40.02	Malignant neoplasm of scapula and long bones of left upper limb
C40.10	Malignant neoplasm of short bones of unspecified upper limb
C40.11	Malignant neoplasm of short bones of right upper limb
C40.12	Malignant neoplasm of short bones of left upper limb
C40.20	Malignant neoplasm of long bones of unspecified lower limb
C40.21	Malignant neoplasm of long bones of right lower limb
C40.22	Malignant neoplasm of long bones of left lower limb
C40.30	Malignant neoplasm of short bones of unspecified lower limb
C40.31	Malignant neoplasm of short bones of right lower limb
C40.32	Malignant neoplasm of short bones of left lower limb
C40.80	Malignant neoplasm of overlapping sites of bone and articular cartilage of unspecified limb
C40.81	Malignant neoplasm of overlapping sites of bone and articular cartilage of right limb
C40.82	Malignant neoplasm of overlapping sites of bone and articular cartilage of left limb
C40.90	Malignant neoplasm of unspecified bones and articular cartilage of unspecified limb
C40.91	Malignant neoplasm of unspecified bones and articular cartilage of right limb
C40.92	Malignant neoplasm of unspecified bones and articular cartilage of left limb
C41.0	Malignant neoplasm of bones of skull and face
C41.4	Malignant neoplasm of pelvic bones, sacrum and coccyx
C41.9	Malignant neoplasm of bone and articular cartilage, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

Table E1 summarizes incidence, in decreasing order, of lesions that may present as a primary bone tumor.

MULTIPLE MYELOMA:
- The most common tumor in bone
- Age at onset: Usually >40 yr
- Male/female ratio of 2:1

OSTEOGENIC SARCOMA:
- Average age at onset: 10 to 20 yr
- Males afflicted more often than females
- Parosteal sarcoma in older patients

CHONDROSARCOMA:
- Age at onset: 40 to 60 yr
- Male/female ratio of 2:1

EWING SARCOMA: Age at onset: 10 to 15 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

MULTIPLE MYELOMA:
- May present as a systemic process or, less commonly, as a "solitary" extramedullary lesion
- Early manifestations: Anorexia, weight loss, and bone pain; majority of cases present initially with back pain that often leads to the detection of a destructive skeletal lesion
- Other organ systems eventually become involved, resulting in more bone pain, anemia, renal insufficiency, and/or bacterial infections, usually as a result of the dysproteinemia typical of this disorder
- Possible secondary amyloidosis, leading to cardiac failure or nephrotic syndrome

OSTEOSARCOMA:
- Most originating in the metaphysis
- 50% to 60% around the knee
- Possible pain and swelling, but otherwise healthy patient
- Osteosarcoma in conjunction with Paget disease, manifested primarily as a sudden increase in bone pain

CHONDROSARCOMA:
- Tumor most commonly involving the pelvis, upper femur, and shoulder girdle
- Painful swelling

EWING SARCOMA:
- Painful soft tissue mass often present
- Possibly increased local heat
- Midshaft of a long bone usually affected (in contrast to other tumors)
- Weight loss, fever, and lethargy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteomyelitis
- Metastatic bone disease

LABORATORY TESTS

- Slightly elevated alkaline phosphatase in osteosarcoma
- In Ewing sarcoma: Reflective of systemic reaction; includes anemia, an increase in white blood cell count, and an elevated sedimentation rate
- In multiple myeloma:
  1. Bence Jones protein in the urine
  2. Anemia and elevated erythrocyte sedimentation rate
  3. Characteristic dysproteinemia on serum protein electrophoresis showing a monoclonal spike
  4. Elevated quantitative immunoglobulins, beta-2 microglobulin, and elevated kappa:lambda ratio upon serum-free light chain assay
  5. Rouleaux formation in the peripheral blood smear

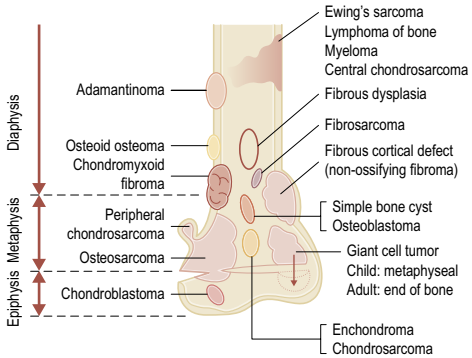

FIG. E1 Site of origin of bone tumors. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

TABLE E1 Incidence, in Decreasing Order, of Lesions That May Present as a Primary Bone Tumor

Lesion	Incidence of All Tumors (%)†,‡
Osteosarcoma	17
Chondrosarcoma	11
Enchondroma*	6
Fibrous dysplasia*	6
Giant cell tumor	6
Nonossifying fibroma/fibrous cortical defect*	5
Ewing sarcoma	5
Malignant fibrous histiocytoma/fibrosarcoma	5
Osteochondroma*	4
Aneurysmal bone cyst	4
Metastasis	4
Osteomyelitis	4
Solitary bone cyst	3
Osteoid osteoma	3
Langerhans cell histiocytosis (eosinophilic granuloma)	3
Chondroblastoma	2
Others	12

*Lesions are often asymptomatic and therefore much more frequent than the table suggests.
†Benign tumors and tumor-like lesions in general are underreported in these frequency distributions.
‡Data are based on 6873 tumors on file in the Netherlands Committee on Bone Tumors.
From Pope TL et al: *Musculoskeletal imaging*, ed 2, Philadelphia, 2015, Elsevier.

TABLE E2 Systemic Approach in Diagnosing Osseous Tumors or Tumor-Like Lesions

1. Categorize the radiograph (normal, variant, tumor-like lesion, tumor).
2. Determine the prevalence of lesions in relation to the age of the patient.
3. Determine the prevalence of lesions in the affected bone.
4. Is the lesion solitary, or are there multiple lesions?
5. Determine the prevalence of osseous lesions in the affected part of the bone.
6. Analyze the radiograph in detail.
7. Analyze additional information (MR, CT, clinical and laboratory data, and so on).
8. Perform a biopsy, if needed, based on the comprehensive imaging findings.

From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.

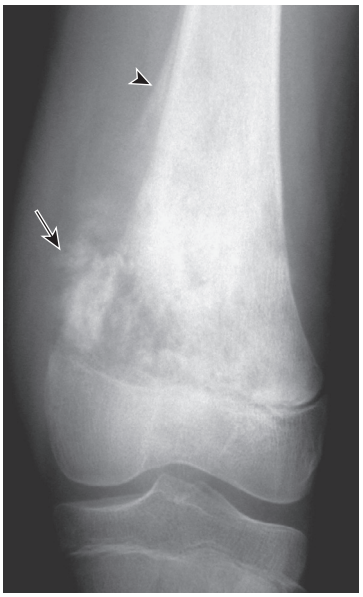

FIG. E2 Conventional central osteosarcoma. AP radiograph of the distal femur showing a classic osteosarcoma with mixed lytic and sclerotic areas, tumor bone formation in the extraosseous mass *(arrow)*, and a proximal Codman's triangle *(arrowhead)*. (From Adam A et al: *Grainger & Allison's diagnostic radiology,* ed 5, Philadelphia, 2008, Churchill Livingstone.)

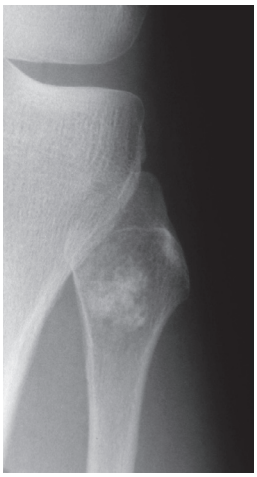

FIG. E3 Chondrosarcoma. AP XR showing a mineralized lesion of the fibula due to low-grade chondrosarcoma. The lesion cannot be radiologically differentiated from a chondroma. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

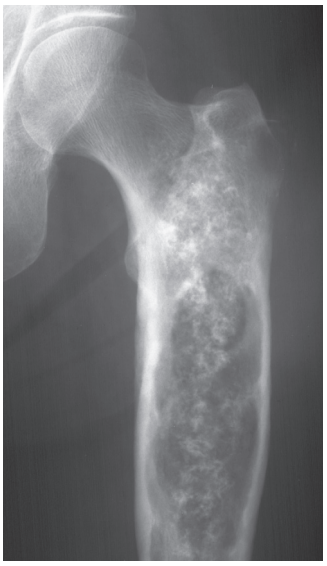

FIG. E4 AP radiograph of the femur showing an extensive central chondrosarcoma with typical chondroid matrix, cortical expansion and thickening with endosteal scalloping. (From Grant, LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

6. Often presence of hypercalcemia
7. Elevated serum lactate dehydrogenase (LDH)

IMAGING STUDIES

- Table E2 summarizes a systemic approach in diagnosing osseous tumors or tumor-like lesions.
- Classic osteogenic sarcoma penetrates the cortex early in many cases.
  1. A blastic (dense), lytic (lucent), or mixed response may be seen in the affected bone (Fig. E2).
  2. An aggressive perpendicular sunburst pattern may be present as a result of periosteal reaction, and peripheral Codman triangles are often noted.
  3. Margins of the tumor are poorly defined.
- Speckled calcifications in a destructive radiolucent lesion are usually suggestive of chondrosarcoma (Figs. E3, E4, and E5).
- Ewing sarcoma is characterized radiographically by mottled, irregular destructive changes with periosteal new bone formation. The latter may be multilayered, producing the typical "onion skin" appearance.
- Typical x-ray finding in multiple myeloma is the "punched out" lesion with sharply demarcated edges.
  1. Multiple lesions are usual.
  2. Diffuse osteoporosis may be the only finding in many cases.
  3. Pathologic fractures are common.
- In multiple myeloma, MRI scans or PET are routinely utilized for the purposes of staging

FIG. E5 Dedifferentiated chondrosarcoma. AP XR showing a proximal femoral chondrosarcoma with an adjacent area of lytic destruction and a pathological fracture. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

extent of disease and also for monitoring for response and/or disease progression.

Rx TREATMENT

The evaluation and treatment of malignant bone tumors are complicated. Diagnostic studies and treatment should be supervised by an orthopedic cancer specialist and oncologist.

DISPOSITION

- In the past 20 yr, dramatic improvements have been made in the treatment protocols for osteosarcoma with the use of adjuvant multidrug regimens and limb-sparing surgery.
- Prognosis of multiple myeloma has markedly improved with introduction of several newer therapies, including proteasome inhibitors, immunomodulatory drugs, histone deacetylase inhibitors, and monoclonal antibodies. Additionally, immunotherapy approaches with checkpoint inhibitors are under investigation with promising initial results.
- Prognosis for Ewing sarcoma has improved with a combination of chemotherapy, local resection, and radiation therapy.
- Chondrosarcomas are not sensitive to chemotherapy or radiation, and prognosis depends on the grade of the tumor and the ability to obtain an adequate resection.

PEARLS & CONSIDERATIONS

Early diagnosis is important because most bone tumors are initially localized and have not metastasized at the time of initial presentation. In multiple myeloma, early utilization of autologous stem cell transplantation confers a survival benefit in eligible patients.

Sarcoma (Related Key Topic)

AUTHOR: **Bharti Rathore, MD**

BASIC INFORMATION

DEFINITION

Borderline personality disorder (BPD) is characterized by a pervasive pattern of instability in interpersonal relationships, self-image, affect regulation, and impulse control that causes significant subjective distress or impairment of functioning. The individual must meet five or more of the following criteria:

1. Frantic efforts to avoid real or imagined abandonment
2. Unstable and intense personal relationships characterized by alternating between extremes of idealization and devaluation
3. Identity disturbance characterized by an unstable self-image
4. Impulsivity in at least two areas that are potentially self-damaging (e.g., overspending, sex, substance abuse, binge eating, reckless driving)
5. Recurrent suicidal behavior, gestures, threats, or self-mutilating behavior
6. Affective instability due to a marked reactivity of mood
7. Chronic feelings of emptiness
8. Inappropriate, intense anger or difficulty controlling anger
9. Transient, stress-related paranoid ideation or severe dissociative symptoms

SYNONYM

BPD

ICD-10CM CODES
F60.3 Emotionally unstable personality disorder
F60.3 Borderline personality disorder
DSM-5 CODE
301.83

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Affects approximately 1% to 3% of the general population and up to 10% of psychiatric outpatients
PREDOMINANT SEX: Female (3:1) historically, although recent studies indicate fewer gender disparities
PREDOMINANT AGE: 20s
GENETICS: BPD is five times as likely if disorder is present in a first-degree relative. Increased prevalence of mood disorders and substance abuse disorders also found in first-degree relatives
RISK FACTORS: Association with childhood physical, sexual, or emotional abuse and/or neglect

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination may reveal scarring from self-injury on arms, legs, or other areas of the body. Mental status examination may reveal affective lability.
- Clinical presentation may reveal the following:
  1. A pervasive sense of loneliness and emptiness
  2. Underlying negative affect with dysphoria
  3. High frequency of comorbid psychiatric disorders, especially posttraumatic stress disorder (PTSD), anxiety disorders generally, mood disorders, attention-deficit/hyperactivity disorder, and substance use disorders
  4. Intense emotions with difficulty returning to emotional baseline
  5. All-or-nothing, either/or cognitive style that is represented by a phenomenon known as "splitting," in which patient sees situations or people as all good or all bad
  6. Difficulty in maintaining commitment to long-term goals; history of numerous stormy relationships and multiple jobs
  7. Reports a high number of sexual partners due to either/both impulsivity and victimization
  8. Reacts with rage, panic, despair to actual or perceived abandonment; may present with suicidality or self-mutilating behavior in response to recent stressor
  9. Attempts to block the experience of pain, which may induce feelings of derealization, depersonalization, changes in consciousness, and/or brief psychotic reactions with delusions and hallucinations
  10. Substance use, gambling, overspending, eating binges, and/or self-injury as a way to escape intensely painful affect

ETIOLOGY

- Interaction of psychosocial adversity plus genetic factors
- Hypotheses:
  1. Genetic: Increased risk if first-degree relative with BPD
  2. Biologic: Abnormalities in limbic system and other areas of the brain cause emotional dysregulation. Serotonergic functioning appears to be disturbed
  3. Environmental: History of childhood abuse (most commonly sexual), invalidation, or neglect

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Histrionic, antisocial, and narcissistic personality disorders share some common features.
- Persistent depressive disorder and other depressive disorders: Requires a stability of affective symptoms not seen in BPD.
- Bipolar disorder: Mood changes in BPD often triggered by stressors and less sustained than in bipolar disorder.
- Substance abuse or dependence: Often induces impulsive, emotionally labile behavior.
- PTSD: Individuals with BPD often have history of trauma but do not avoid the feared stimulus or reexperience the trauma, as with PTSD.
- Mild cases of schizophrenia may superficially resemble BPD.

UNDERDIAGNOSIS AND MISDIAGNOSIS

- BPD may be underdiagnosed, particularly in outpatient settings that do not permit long-term observation.
- Screening for BPD should include assessment of the most common features of affective instability and chronic anger, particularly in young adults.
- Many patients with BPD are incorrectly diagnosed with bipolar disorder. Cyclothymia, which is a subtype of bipolar disorder in DSM-5, is characterized by separation-related affective sensitivity and frequent depressive and hypomanic episodes, may be most difficult to distinguish from BPD.
- Onset usually occurs in adolescence. Features should not be dismissed as normal adolescent behavior.

WORKUP

- History (helpful to gather collateral information from family and friends)
- Physical examination: Neurological soft signs may reflect a vulnerability to impulsivity and affect storms
- Mental status examination

LABORATORY TESTS

- Toxicology screen; substance use is common and can mimic features of personality disorders.
- Screen for HIV and other sexually transmitted illnesses.

IMAGING STUDIES

Structural and functional MRI demonstrate amygdala hyperactivity, reduced hippocampus and amygdala volume, greater activation within the insula and posterior cingulate cortex, and less activation in regions extending from the amygdala to the cingulate and prefrontal cortex. Positron emission tomography (PET) scans reveal reduced metabolism in prefrontal cortex. Recent PET research reveals dysregulation of endogenous opioid function. Lower cortical gray matter density may be noted on MRI. Imaging is not recommended as part of routine evaluation.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Psychotherapy is the recommended primary treatment for BPD.
- Dialectical behavior therapy (DBT), mentalization-based therapy, variations of cognitive behavior therapy (CBT), and psychodynamic therapies (including transference-focused therapy) have the most empirical support from randomized trials and recent meta-analyses. Nonetheless, effects are small and unstable at long-term follow-up.
- The goal of DBT and most CBT variations is to help patients improve mindful awareness of emotions, control impulsive behaviors and angry outbursts, and develop social skills. In mindfulness treatment, the emphasis is on teaching patients to stand outside of their

feelings and observe emotions in themselves and others. The focus of transference-focused psychotherapy is on examining the affect-laden themes that emerge in the relationship between patient and therapist. Preliminary evidence exists for effectiveness of more integrative treatment models, such as the unified protocol and mindfulness-based therapies generally. Positive outcomes are also reported using "good psychiatric management" (GPM), which combines principles from various therapies and emphasizes psychoeducation and goal-setting. Effective therapeutic treatments typically combine weekly group and individual therapy meetings.
- Treatment may also include inpatient and partial hospitalization in more severe cases.

ACUTE GENERAL Rx

Low-dose antipsychotics to control impulsivity, brief psychotic episodes.

CHRONIC Rx

- Medications have low to moderate effectiveness and are most effective in improving symptoms of impulsivity, mood instability, and self-destructive behavior. Effectiveness only studied for the first 3 mo of treatment.
- SSRIs if concurrent mood disorder. Higher doses may be required than for major depression.
- Low-dose antipsychotics.
- Mood stabilizers (lithium, valproate, carbamazepine, topiramate).
- Lamotrigine is not effective in the treatment of BPD in placebo-controlled trials.
- In preliminary studies, omega-3 fatty acids improve irritability.

DISPOSITION

- Course is variable. The most unstable period is typically in early adulthood; the majority achieve greater stability in social/occupational functioning later in life but often continue with difficulty maintaining intimate relationships.
- Clinically salient features such as alcohol/substance use and self-injury may be less common in older adults.
- Often presents in emergency room when in acute distress.
- No evidence of progression to schizophrenia, but there is a high incidence of concurrent major depression and other psychiatric disorders.
- Patients with high pretreatment symptom severity who report and maintain a strong therapeutic alliance with their providers report highest treatment benefits.
- Drop-out rates are variable in research studies and may be high for individual patients.

REFERRAL

- Referral to mental health specialist:
  1. For diagnosis and management
  2. Use of pharmacotherapy
  3. Patient is severely impaired or suicidal

PEARLS & CONSIDERATIONS

COMMENTS

- Negative perceptions of patients with BPD among health care providers have potential to limit accurate diagnosis, access to care, and quality of treatment provided.
- Approach making the diagnosis of BPD in the same clear, straightforward way you would any other psychiatric diagnosis. Patients who are and are not diagnosed with BPD report equal satisfaction with their doctors regardless of diagnosis received.
- Consider frequent, brief, scheduled visits for needy, demanding, or somaticizing patients with BPD.
- Validate the patient's feelings while stating the expectation of behavior control.
- Be matter-of-fact; avoid expressing extreme emotions.
- Be alert to the risk of suicide and assess suicide risk often.
- Be alert to the risk of nonsuicidal self-harm, such as cutting.
- Convey a demeanor of competence but openly acknowledge minor errors.
- Have a low threshold for seeking psychiatric consultation.
- Patients commonly present with high functional impairment across multiple settings. Psychosocial impairment as great as, or even greater than, that of bipolar disorder.
- An alternative model of diagnosing borderline personality disorder exists in the DSM-5 section III, consisting of: (1) impairment in personality functioning (identity, self-direction, empathy, or intimacy) and (2) four or more of seven maladaptive personality traits (emotional lability, anxiousness, separation insecurity, depressivity, impulsivity, risk-taking, and hostility).

PREVENTION

- There are no known ways to prevent BPD (or other personality disorders).
- Suicidality should be actively and consistently monitored.
- Benzodiazepines, narcotic analgesics, and other drugs with potential for dependency should be used rarely and with great caution, due to impaired impulse control and risk of addictive behavior.
- Patients should be asked frequently and in detail about parenting practices. Low frustration tolerance, externalization of blame for psychological distress, and impaired impulse control put children at risk for neglect or abuse.

PATIENT & FAMILY EDUCATION

- National Alliance for the Mentally Ill (NAMI; www.nami.org) provides patient information, online chat groups, and information on support groups throughout the U.S. for people with BPD and their families.
- National Education Alliance for Borderline Personality Disorder (NEA BPD) provides online patient, family, and professional information on BPD.
- Additional, local and/or online support groups for BPD are common and should be investigated.

BASIC INFORMATION

DEFINITION

Botulism is an illness caused by a neurotoxin produced primarily by *Clostridium botulinum.* Five types of disease can occur: Foodborne botulism, wound botulism, infant intestinal botulism, adult enteric botulism (similar to infant botulism), and inhalational botulism. Of note, inhalational botulism is exceedingly rare, but could occur as a result of bioterrorism.

SYNONYMS

Clostridium botulinum food poisoning
Botulinum toxin food poisoning
Wound botulism
Infantile botulism

ICD-10CM CODES	
A05.1	Botulism food poisoning
A48.51	Infant botulism
A48.52	Wound botulism

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): In 2016, 205 cases of botulism were reported in the U.S. Foodborne botulism accounts for 20% of cases; over 70% of cases are infant botulism. Systemic botulism toxicity resulting from cosmetic use of botulinum toxin is exceedingly rare and has only been reported with unlicensed use.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms usually begin 12 to 36 hr following ingestion of the toxin
- Severity of illness is related to the quantity of toxin ingested
- Significant findings:
  1. Acute, bilateral cranial nerve palsies, with ocular and bulbar manifestations being most frequent (diplopia, ophthalmoplegia, ptosis, dysphagia, dysarthria, fixed and dilated pupils, and dry mouth)
  2. Bilateral motor nerve involvement that may progress to a descending flaccid paralysis
  3. No sensory deficits aside from possible blurred vision
  4. GI symptoms (dry mouth, nausea, vomiting, diarrhea, or cramps)
  5. Normal heart rate, blood pressure, and temperature
  6. Normal mental status
- Wound botulism:
  1. Occurs primarily in injection drug users (subcutaneous "black tar" heroin injection—"skin popping") or with traumatic injury
  2. Presentation is similar to that of foodborne disease, except for a longer incubation period (4 to 14 days) and absence of GI symptoms
  3. Fever is uncommon and if present may be due to wound infection, which is not always apparent

ETIOLOGY

- Botulism is caused by one of several neurotoxins (usually A, B, E, or F) produced by *C. botulinum,* an anaerobic, gram-positive bacillus. Spore production guarantees survival of the organism in extreme conditions; it is found worldwide. Botulinum toxin blocks acetylcholine-mediated neurotransmission and is the most powerful neurotoxin known.
- Disease results from absorption of toxin into the circulation from a mucosal surface or wound. Botulinum toxin does not penetrate intact skin.
- In foodborne botulism, disease is caused by ingestion of preformed toxin. Although rapidly inactivated by heat, the toxin can survive the proteolytic environment of the stomach.
- In wound botulism, toxin is elaborated by organisms that contaminate a wound.
- In infant botulism (and probably adult botulism of unknown etiology), toxin is produced by organisms in the GI tract. Antibiotic use and achlorhydria can predispose to colonization by *C. botulinum* and elaboration of toxin.
- Inhalational botulism has been demonstrated experimentally in primates. Rare case reports of inhalational botulism from snorting contaminated cocaine have been reported, and there is concern for the potential use of manufactured aerosolized toxin as a bioterrorism agent.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Myasthenia gravis, Lambert-Eaton myasthenic syndrome
- Guillain-Barré syndrome or other acute inflammatory demyelinating polyneuropathy
- Tick paralysis
- Stroke
- Polio
- Acute flaccid myelitis
- Heavy metal intoxication
- Shellfish poisoning

LABORATORY TESTS

- Treatment should start *before* laboratory confirmation in suspected cases, as laboratory testing may take several days.
- Serum, food, and/or stool should be sent for anaerobic cultures and toxin assay.
- Public health laboratories may perform mouse bioassay testing, which confirms toxin type in 75% of cases. Immunoassays and PCRs are under investigation for rapid source tracking.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive care with intubation if respiratory failure occurs; ventilation may need to continue for some time, as pharmacologic therapy halts only short-term disease progression.
- Debridement of the wound in wound botulism.

ACUTE GENERAL Rx

- **For non-infants:** Give equine heptavalent botulinum antitoxin (HBAT), which contains antibodies for seven known botulism types (A through G), as early as possible. Antitoxin should be administered before laboratory confirmation if botulism is suspected.
  1. The antitoxin (BAT, Cangene Corporation) is available from the Centers for Disease Control and Prevention (1-404-639-2206 Monday through Friday or 1-404-639-2888 evenings/weekends); it is derived from horse serum, so there is a significant incidence of serum sickness.
  2. Skin testing (conjunctival instillation and observation for 15 min), and possible desensitization, is recommended before treatment. Reported hypersensitivity rates range from 9% to 20%.
- Give wound botulism patients penicillin 3 million U IV q4h after antitoxin has been administered. Use metronidazole 500 mg IV q8h as an alternative for penicillin-allergic patients. Avoid aminoglycosides and tetracyclines, as they are ineffective and can worsen neuromuscular blockade.
- **For infants:** Give human botulinum immunoglobulin (BabyBIG) IV as a single dose as early as possible. Immune globulin should be administered before laboratory confirmation if botulism is suspected. Call 1-510-231-7600 to begin the process of drug acquisition and for administration instructions. Do not use equine antitoxin. Babies with infantile intestinal botulism may benefit from a cathartic to mechanically clear the number of *C. botulinum* vegetative forms and spores residing in the gastrointestinal tract. Avoid antibiotics in infant botulism because antimicrobials may lyse *C. botulinum* in the gut and increase toxin load.

DISPOSITION

- Highest mortality in the first cases in an outbreak, with subsequent cases receiving rapid treatment.
- Complete recovery for most individuals (may take up to 1 yr).

PEARLS & CONSIDERATIONS

COMMENTS

- Routine cooking inactivates the toxin, but spores are resistant to environmental factors. At room temperature, spores can germinate and produce toxin. Pressure cooking can kill spores.
- Most outbreaks are associated with home-canned foods, including fruits, vegetables, and fish. Botulinum spores can be found in honey and corn syrup, and thus children under 12 months of age should not eat honey or foods with honey in them.
- Patients must be closely monitored for progression to respiratory failure.

- Notify public health authorities immediately to alert other health care services of possible additional cases and to initiate investigation into cause and scope of outbreak.
- Immunity to botulism does not occur after toxin exposure/infection, and repeated botulism can occur.

RELATED CONTENT

Botulism (Patient Information)

AUTHORS: **Stephen Dolter, MD,** and **Russell J. McCulloh, MD**

BASIC INFORMATION

DEFINITION

A brain abscess is a focal intracerebral infection that can arise as a complication of a bacterial, mycobacterial, fungal, or parasitic infection, or as a sequelae after surgery or trauma.

ICD-10CM CODE
G06.0 Intracranial abscess and granuloma

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Uncommon (reported incidence 0.4 to 0.9 cases per 100,000 population; occurs about 2% as commonly as brain tumors)
PEAK INCIDENCE: Preadolescence and middle age (and depends on predisposing condition); increased rates in the immunocompromised host
PREDOMINANT AGE: Occurs at any age
PREDOMINANT SEX: Men affected more than women (ratio 2:1 to 3:1)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic triad: Fever, headache, and focal neurologic deficit (present in approximately 20% of cases).
- Clinical presentation is often due to the manifestations of the space-occupying lesion rather than to signs of systemic infection.
- Fever is present in only 32% to 79% of patients.
- Headache is usually localized to the side of the abscess; onset can be gradual or severe; present in an average of 70% to 75% of cases.
- Focal neurologic findings (e.g., seizures, hemiparesis, aphasia, ataxia) depend on the location of the abscess and are seen in 23% to 66% of cases.
- Papilledema is present in 9% to 51% of cases.
- Presence of adjacent infections (dental abscess, otitis media, sinusitis, or postneurosurgical infection) may be a clue to the underlying diagnosis and should be sought in any suspected case.
- Time course from symptom onset to presentation ranges from hours in fulminant cases to more than 1 month; 75% present in the first 2 weeks.
- The nonspecific presentation of a brain abscess warrants that clinicians maintain a high index of suspicion. Table 1 describes common initial features of brain abscess.

ETIOLOGY

- Brain abscesses are classified based on the likely portal of entry and can arise from:
  1. Contiguous infection (e.g., dental abscess, otitis media, sinusitis, or post neurosurgical infection)
  2. Hematogenous spread from a remote site (e.g., endocarditis, bacteremia), which typically causes multiple lesions

TABLE 1 Brain Abscess: Initial Features in 123 Cases

Headache	55%
Disturbed consciousness	48%
Fever	58%
Nuchal rigidity	29%
Nausea, vomiting	32%
Seizures	19%
Visual disturbance	15%
Dysarthria	20%
Hemiparesis	48%
Sepsis	17%

From Goldman L, Schafer AI: *Goldman's Cecil medicine*, ed 24, Philadelphia, 2012, Saunders.

- Likely source of abscess and common organisms involved:
  1. Contiguous focus or primary infection (55% of all brain abscesses):
     a. Paranasal sinus: Occur in frontal lobe; streptococci (especially microaerophilic and anaerobic streptococci), *Bacteroides*, *Haemophilus*, and *Fusobacterium* spp.
     b. Otitis media/mastoiditis: Occur in temporal lobe and cerebellum; aerobic and anaerobic streptococci, *Enterobacteriaceae*, *Bacteroides*, and *Pseudomonas* spp.
     c. Dental infection: Occur in frontal lobe; mixed *Fusobacterium*, *Bacteroides*, and *Streptococcus* spp. (especially *S. viridans* and anaerobic streptococci)
     d. Penetrating head injury: Site of abscess depends on site of wound; *Staphylococcus aureus*, aerobic streptococci, *Clostridium* spp., *Enterobacteriaceae*
     e. Postoperative: *Staphylococcus epidermidis* and *S. aureus, Enterobacteriaceae,* and *Pseudomonas aeruginosa*
  2. Hematogenous spread from a distant site of infection (25% of all brain abscesses): Abscesses most commonly multiple, especially in middle cerebral artery distribution; infecting organism(s) depend on source
     a. Congenital heart disease: Streptococci, *Haemophilus* spp.
     b. Endocarditis: *S. aureus*, viridans streptococci
     c. Urinary tract: Enterobacteriaceae, Pseudomonadaceae
     d. Intraabdominal: Streptococci, *Enterobacteriaceae*, anaerobes
     e. Lung: streptococci, *Actinomyces* spp., *Fusobacterium* spp.
     f. Immunocompromised host: *Toxoplasma* spp., *Enterobacteriaceae*, *Nocardia* spp., listeriosisi, other fungi, tuberculosis
        (1) Fungi are responsible for up to 90% of cerebral abscesses in solid organ transplant recipients
  3. Cryptogenic (unknown source): 20% of all brain abscesses

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other parameningeal infections: Subdural empyema, epidural abscess, thrombophlebitis of the major dural venous sinuses and cortical veins
- Embolic strokes in patients with bacterial endocarditis
- Mycotic aneurysms with leakage
- Acute hemorrhagic leukoencephalitis
- Parasitic infections: Toxoplasmosis, echinococcosis, cysticercosis
- Metastatic or primary brain tumors
- Cerebral infarction
- CNS vasculitis
- Chronic subdural hematoma

WORKUP

Physical examination, laboratory tests, and imaging studies

LABORATORY TESTS

- White blood cell counts are elevated in 60% of patients.
- Erythrocyte sedimentation rate is usually elevated but may be normal.
- Lumbar puncture is contraindicated because of the potential for increased intracranial pressure and the risk for herniation due to the space-occupying abscess. Lumbar puncture may be helpful only in those with suspicion for meningitis or abscess rupture into the ventricular system; however, the risk of herniation must be considered.
- The yield of gram stain and culture of material aspirated at time of surgical drainage is very high.
- Cultures of contiguous sites of infection should be considered (e.g., paranasal sinus, otitis, skin site abscess from a neurosurgical procedure). These sites of infection may need surgical drainage in order to control the infection.
- Blood cultures and cerebrospinal fluid cultures may identify the causative organism in up to 25% of patients.
- Based on the appearance of lesions on imaging, then antitoxoplasma IgG antibodies from the blood and anticysticercal antibodies in the CSF can aid in the diagnosis of CNS toxoplasma and neurocysticercosis infections, respectively.

IMAGING STUDIES

- CT scan with contrast enhancement or MRI with gadolinium can be used to detect brain abscess. CT is rapid and available in most medical settings. An MRI with gadolinium (Fig. E1) is able to provide more detailed images in order to differentiate between abscess and tumor or other mass.
- CT scan (Fig. 2) with intravenous contrast enhancement is still an excellent test (sensitivity 95% to 99%).
- Serial CT or MRI scanning is recommended to follow the response to therapy.

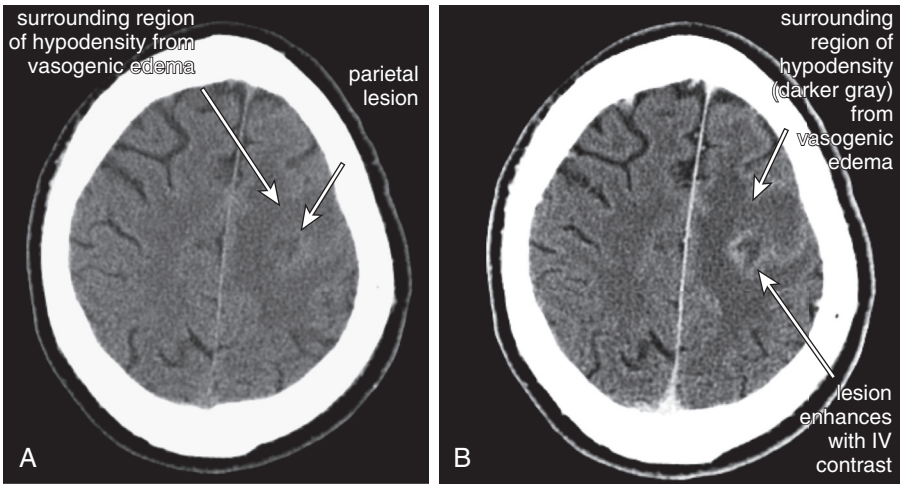

FIG. 2 Brain abscess. This 48-yr-old male presented with status epilepticus. Computed tomography (CT) of the brain showed a parietal mass, which at brain biopsy was found to be an abscess. Cultures grew mixed gram-positive and gram-negative organisms and anaerobes. The patient was subsequently found to be human immunodeficiency virus positive. **A,** Noncontrast head CT, brain windows. **B,** CT with intravenous (IV) contrast moments later, brain windows. Abscesses and other infectious, inflammatory, or neoplastic lesions typically have surrounding hypodense regions representing vasogenic edema. When IV contrast is administered **(B),** the lesion may enhance peripherally, often referred to as ring enhancement. (From Broder JS: *Diagnostic imaging for the emergency physician*, Philadelphia, 2011, Saunders.)

Rx TREATMENT

ACUTE GENERAL Rx

- Effective treatment involves a combination of empiric antibiotic therapy and timely excision or aspiration of the abscess.
- If evidence of edema or mass effect, treatment of elevated intracranial pressure is paramount.
  1. Hyperventilation of mechanically ventilated patient.
  2. Dexamethasone initially in a dosage of 10 mg IV followed by 4 mg IV q6h until symptoms of cerebral edema subside. Steroids should be discontinued as soon as possible.
  3. Mannitol 0.25 to 1 g/kg IV over 20 to 30 min q6 to 8h; maximum of 6 g/kg in 24 hr.
- Medical therapy is never a substitute for surgical intervention to relieve increased intracranial pressure. Neurologic deterioration usually mandates surgical intervention.
- Steroids should be limited to patients with severe cerebral edema or midline shift.

MEDICAL Rx

If abscess <2.5 cm and patient is neurologically stable and conscious, may start antibiotics and observe. Empiric antibiotic therapy guided by:

- Abscess location
- Suspicion of primary source
- Presence of single or multiple abscesses
- Patient's underlying medical conditions (e.g., HIV, immunocompromised)

Selection of empiric antibiotic therapy:

- Primary infection or contiguous source:
  1. Otitis media/mastoiditis, sinusitis: Third-generation cephalosporin (cefotaxime 2 g q4h IV or ceftriaxone 2 g q12h IV) plus metronidazole 15 mg/kg IV as a loading dose, then 7.5 mg/kg q8h IV, not to exceed 4 g per day
  2. Dental infection: Penicillin G (20 million to 24 million units per day IV in six divided doses) plus metronidazole (dose as above)
  3. Head trauma: Third- or fourth-generation cephalosporin (cefotaxime 2 g IV q4h or ceftriaxone 2 g IV q12h or cefepime 2 g IV q8h) plus vancomycin (30 mg/kg IV in two divided doses adjusted for renal function)
  4. Postoperative neurosurgery: Vancomycin (dose as above) plus ceftazidime (2 g IV q8h) or cefepime (2 g IV q8h), or meropenem (1 g IV q8h). Replace vancomycin with nafcillin (2g IV q4h) if susceptibility testing reveals methicillin-sensitive *S. aureus*
- Hematogenous spread (congenital heart disease, endocarditis, urinary tract, lung, intraabdominal): Vancomycin (empiric therapy, dose as above) or nafcillin (if susceptibility testing reveals methicillin-sensitive *S. aureus*, dose as above) plus metronidazole plus third-generation cephalosporin (cefotaxime 2 g IV q4h or ceftriaxone 2 g IV q12h). Antibiotic therapy can be adjusted based on the etiology of the underlying infection, if known. Depending on the source, many experts advocate for anaerobic coverage, even with no documentation given suboptimal sensitivity of current techniques
- HIV-infected or immunocompromised patient: Metronidazole plus a third-generation cephalosporin, antifungal, or antiparasitic agent. Duration of antibiotic therapy is guided by the clinical course and by whether the abscess was surgically aspirated or excised; it is usually prolonged. Most recommend parenteral treatment for at least 4 to 8 weeks, with serial neuroimaging to ensure adequate resolution. (Imaging weekly could be considered for first 2 weeks of therapy, then every 2 weeks until resolution.) Surgical therapy may be required for clinical failure (i.e., increasing size of abscess on imaging despite antibiotic therapy).

SURGICAL Rx

- Three indications for surgical intervention:
  1. Collect specimens for culture and sensitivity
  2. Reduce mass effect
  3. Clinical failure with antibiotic therapy alone
- Stereotactic biopsy or aspirate of the abscess if surgically feasible
- Essential to selection of targeted antimicrobial coverage
- Timing and choice of surgery depend on:
  1. Primary infection source
  2. Number and location of the abscesses
  3. Whether the procedure is diagnostic or therapeutic
  4. Neurologic status of the patient

DISPOSITION

- Prompt diagnostic consideration, early institution of appropriate antimicrobial therapy, and advanced neuroradiologic imaging have reduced the mortality rate from brain abscesses from 40% to 80% in the preantibiotic era to 10% to 20% at present.
- Morbidity is usually manifest as persistent neurologic sequelae (seizures, intellectual or behavioral impairment, motor deficits).

REFERRAL

Consultation with infectious disease and neurosurgery

PEARLS & CONSIDERATIONS

COMMENTS

- It is important to maintain a high index of suspicion because a brain abscess often presents with nonspecific symptoms.
- Rapid imaging and early institution of appropriate antimicrobial therapy improve patient morbidity and mortality.
- Neurosurgical consultation is mandatory.

PREVENTION

Because brain abscesses arise from either contiguous infections or hematogenously from a remote site, early and appropriate treatment of predisposing infections is paramount to prevent brain abscess.

BASIC INFORMATION

DEFINITION

Brain metastases result from a spread of cancers originating in other organs to the brain and are devastating complications of cancer. Brain metastases are the most common intracranial tumors in adults and account for more than one half of brain tumors.

ICD-10CM CODES

C79.89	Secondary malignant neoplasm of other specified sites
C80.0	Disseminated malignant neoplasm, unspecified
C80.9	Malignant neoplasm, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Accurate data on the incidence of metastatic brain disease are not available. Population studies based on review of epidemiological data show an overall incidence of 8.3 to 14.3 per 100,000 population per yr. However, these studies underestimate the true incidence of brain metastases because they rely on historical data from times when diagnostic imaging was poor. Autopsy-based studies are thought to show higher incidence of brain metastases because they identify asymptomatic brain metastases. However, autopsy-based data are now more than 20 yr old. Ultimately, the incidence of metastatic brain malignancy is rising, likely due to improved detection and better control of extracerebral disease.
- In the U.S., an estimated 98,000 to 170,000 new cases occur each yr, representing 24% to 45% of all cancer patients. The incidence is higher in autopsy series, where 20% of patients with systemic disease have brain metastases.

PREDOMINANT SEX AND AGE:

- In patients with systemic malignancies, brain metastases occur in 10% to 30% of adults and 6% to 10% of children. Of these, about 60% of patients are between the ages of 50 and 70 yr.
- There is no definite gender predilection. Some data indicate that metastatic brain malignancy has a higher incidence in men because men have a higher incidence of primary lung cancer.

RISK FACTORS

- In adults, the cumulative incidence (CI) of metastases to the brain depends on the type of primary cancer as follows: Lung cancer (16% to 20% CI), renal cell carcinoma (7% to 10% CI), melanoma (7% CI), breast cancer (5% CI), and colorectal cancers (1% to 2% CI). Lymphoma is also known to metastasize to the brain. These metastatic lesions may or may not be present at the patient's initial presentation. The majority of patients with metastases to the brain have greater than one metastasis. The cancers with the highest association of intracranial hemorrhage include renal cell carcinoma, melanoma, and the less common malignancies of thyroid carcinoma and choriocarcinoma.
- The most common primary pediatric solid tumors associated with metastatic spread include sarcomas, neuroblastoma, and germ cell tumors. Leukemias are well known to seed the CNS. Metastatic disease is usually never seen when a child first presents with malignancy, with the occasional exception of leukemia. For solid tumors, metastatic disease is seen at the time of disease recurrence. Neuroblastoma CNS lesions have a high propensity to hemorrhage.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentations vary depending on where the lesion is located. Brain metastases should be suspected in any cancer patient developing acute neurologic signs or symptoms. Neurologic symptoms, however, are common in patients with systemic cancer. In an analysis of more than 800 patients with neurologic symptoms, brain metastases were found in only 16%.
- Symptoms:
  1. Headache occurs in 40% to 50% of patients with brain metastases. Frequency is higher with metastases located in the posterior fossa, which may result in obstructive hydrocephalus. The headache can be accompanied by nausea, vomiting, focal neurologic signs, and postural variation.
  2. Focal neurologic signs/symptoms are the presenting symptom in 20% to 40% of patients. Hemiparesis is the most frequent complaint. However, the specific neurologic dysfunction depends on the location of the brain metastasis.
  3. Cognitive dysfunction, including memory problems or mood or personality changes, is the presenting problem in 30% to 45% of patients.
  4. Seizures are the presenting symptom for 10% to 20% of patients with metastatic brain tumors and indicate supratentorial metastases.
  5. Acute stroke secondary to hemorrhage into a metastasis, hypercoagulability, or local vascular invasion occurs in 5% to 10% of patients.

ETIOLOGY

The most common mechanism of metastasis to the brain is by hematogenous spread. The most common location is at the junction of the gray matter and white matter of the cerebral hemispheres (almost 80%). The blood vessels decrease in diameter in these regions, which is thought to act like a trap for clumps of tumor cells. Different tumor types have a tendency to metastasize to different regions of the brain. For example, metastases of small cell lung carcinoma are equally distributed in all regions, whereas pelvic (prostate and uterine) and gastrointestinal tumors more commonly metastasize to the posterior fossa.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary brain tumor
- Infection: Bacterial abscess or fungal disease
- Progressive multifocal leukoencephalopathy
- Demyelinating disease: Multiple sclerosis, post-infectious encephalomyelitis
- Cerebral infarction or bleeding
- Effects of treatment, such as radiation necrosis

LABORATORY TESTS

- Routine laboratory studies are not typically helpful.
- Lumbar puncture is generally contraindicated due to increased intracranial pressure and risk of herniation.
- Brain biopsy is necessary in some cases for a definitive diagnosis, particularly in the case of unknown primary tumor. Illustrating this situation is a study of cancer patients with solitary brain lesions that were presumed to be metastatic disease; in about 10% of study participants, the lesions were proved to be a different pathology.

IMAGING STUDIES

- MRI (Fig. 1) with and without contrast is the imaging study of choice. Important features on MRI suggesting brain metastases include: Presence of multiple lesions, localization at the junction of the gray and white matter, circumscribed margins, or large amounts of vasogenic edema. CT of the head with contrast (Fig. 2) can be used when MRI is contraindicated.

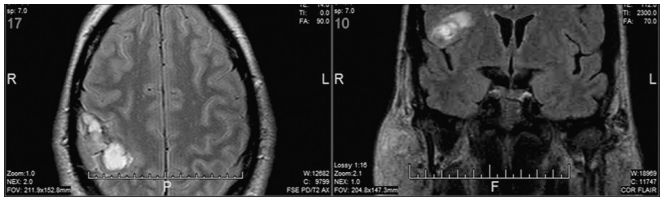

FIG. 1 Brain magnetic resonance imaging (axial and coronal fluid-attenuated inversion recovery sequences) showing hemorrhagic metastatic deposition in the inferior right frontoparietal lobe (lobulated high signal focus) in a 40-yr-old woman with metastatic choriocarcinoma to the brain. (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, WB Saunders.)

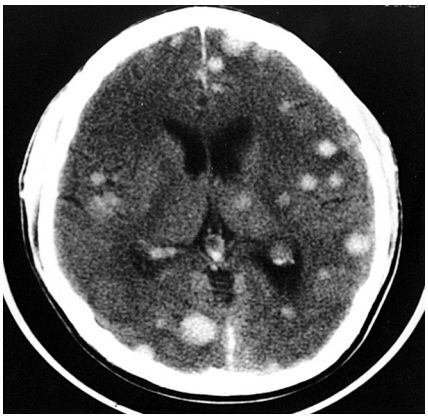

FIG. 2 Intracranial metastatic disease. Axial contrast-enhanced CT scan of head reveals multiple enhancing nodules throughout gray and white matter structures consistent with metastatic disease. (From Vincent JL et al [eds]: *Textbook of critical care*, ed 6, Philadelphia, 2011, WB Saunders.)

- MR spectroscopy and PET are useful to differentiate tumor from either other space-occupying lesions or radiation necrosis.
- Newer experimental imaging studies, such as receptor-targeted and ligand-based molecular imaging, are on the horizon.
- In about 80% of patients, brain metastases develop after the diagnosis of systemic cancer. In the remaining patients, brain metastases are diagnosed either simultaneously or before the primary tumor is found. In patients without a known primary tumor, the lung should be the primary focus of evaluation. Other frequent primary cancer types include melanoma, colon cancer, and breast cancer. PET scan may be useful in these patients to help identify either the primary tumor or other sites of metastatic disease, which may be more amenable to biopsy.

Rx TREATMENT

- Management of patients with brain metastases is influenced by the overall prognosis and may include treatments targeted at the metastases, management and prevention of complications (seizures, edema), and treatment of systemic malignancy.
- In patients considered to have a favorable prognosis (i.e., one to three metastases, good Karnofsky performance score, and controlled or absent systemic disease), treatment focuses on surgical resection and stereotactic radiation either to eradicate or control the brain metastases. Whole-brain radiation (WBRT) is widely used but has significant side effects. A study through the European Organisation for Research and Treatment of Cancer (EORTC), along with prior randomized studies, has shown the addition of WBRT did not improve overall survival but seemed to reduce the rates of disease relapse. A meta-analysis of five randomized controlled trials found that WBRT decreased the relative risk of intracranial disease progression at 1 yr by 53% but did not improve survival. Additionally, the individuals who did not receive WBRT after stereotactic radiosurgery or surgery had better quality-of-life scores. Unfortunately, few patients with metastatic disease are able to meet inclusion criteria for such studies.
- In patients with poor prognosis, treatment focuses on symptom control and WBRT.

ACUTE GENERAL Rx

- Steroids are used to reduce peritumoral edema and intracranial pressure.
- Antiepileptics are started for patients who present with seizures. Prophylactic treatment for seizures is not indicated in patients without a prior history of seizure.
- Anticoagulants are sometimes used to prevent venous thromboembolic disease but should be used with caution in patients with brain metastases that are at increased risk of hemorrhage.

CHRONIC Rx

- Radiation therapy has become the mainstay of treatment for brain metastases, including whole brain radiation therapy and stereotactic radiosurgery (SRS).
- For highly chemosensitive tumors, chemotherapy has been integrated into the primary management of patients with disseminated disease.
- For other tumors (e.g., small cell and non–small cell lung cancers, breast cancer, melanoma) systemic chemotherapy or molecularly targeted agents may be of palliative value when surgery, whole brain radiation therapy, and SRS have failed or are inappropriate. In most cases, two to three agents in combination are used in conjunction with whole brain radiation therapy. A phase II trial has shown combination treatment of lapatinib, an epidermal growth factor receptor inhibitor (EGFR-inhibitor), and capecitabine, an antimetabolite prodrug that is converted to 5-fluorouracil, as active for first-line treatment of *HER2*-positive breast brain metastases. Another phase II trial showed sagopilone (low-molecular-weight epothilone B analogue) as showing modest activity in patients with metastatic breast cancer. Additionally, dabrafenib, a tyrosine kinase inhibitor of *BRAF,* had some activity and an acceptable safety profile for metastatic melanoma with $BRAF^{V600E}$ mutations. Ipilimumab, a monoclonal antibody against cytotoxic T-lymphocyte antigen 4, was used for patients with metastatic melanoma and showed an improved median overall survival of 7 mo in clinically asymptomatic lesions and 3.7 mo in patients with neurologic symptoms. There are also other reports of its efficacy.

DISPOSITION

- The median survival of patients who receive supportive care and are treated with corticosteroids only is approximately 1 to 2 mo.
- Key prognostic factors are performance status, extent of systemic disease, and age. Most favorable outcome is found in patients with Karnofsky performance score ≥70, age younger than 70 yr, no systemic disease or local control of primary tumor without extracranial metastases, and female gender. In this group, median survival is estimated at 7.1 mo.

REFERRAL

Treatment involves a multispecialty team. Consultations from oncology, neurosurgery, neurology, radiation oncology, psychiatry, and physical therapy are all warranted.

! PEARLS & CONSIDERATIONS

COMMENTS

- Brain metastases are the most common intracranial tumors in adults, accounting for more than half of all brain tumors.
- Lung cancer, melanoma, renal cell carcinoma, and breast cancer are the most common primary tumors that metastasize to the brain.
- MRI of the brain with and without contrast is the most reliable imaging study.
- Treatment depends upon the patient's overall prognosis.

Brain Cancer (Patient Information)

AUTHORS: **A. Basit Khan, MD, Joseph S. Kass, MD, JD, FAAN,** and **Nicole J. Ullrich, MD, PhD**

BASIC INFORMATION

DEFINITION

Brain neoplasms are a diverse group of primary (nonmetastatic) tumors arising from one of many different cell types within the central nervous system (CNS). Specific tumor subtypes and prognosis depend on the tumor cell of origin, certain genetic markers, and pattern of growth. The diffuse low-grade gliomas (LGGs) include World Health Organization grade II astrocytomas, oligodendrogliomas, and oligoastrocytomas.

SYNONYMS

Low-grade glioma (LGG)
Glioneuronal tumor
Meningioma
Primary brain tumor

ICD-10CM CODE
D33.2 Benign neoplasm of brain, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: U.S. incidence rate of a new brain tumor is approximately 6.4/100,000 persons per yr for all primary brain tumors (Table 1). One third of these are considered malignant and the remainder benign or borderline malignant. The incidence rate in children aged 0 to 19 yr is lower (5.6 per 100,000 children). Primary brain neoplasms account for ~2% of all cancers, with a disproportionate share of cancer morbidity and mortality. It is the most common cause of cancer death in children up to 15 yr.

PEAK INCIDENCE: Depends on histology, though highest peak at ~age 50 yr.

PREDOMINANT SEX AND AGE: Slight male predominance of malignant brain tumors (8.0 vs. 5.5/100,000 person/yr). Men account for slightly less than half of cases of both benign and malignant brain tumors, as meningiomas have a higher incidence in women.

GENETICS: Most primary CNS neoplasms are sporadic; 5% are associated with hereditary syndromes that predispose to neoplasia. The most common of these include:

- Li-Fraumeni syndrome: *p53* mutation on chromosome 17q13, gliomas
- Von Hippel-Lindau: VHL, chromosome 3p25, hemangioblastoma
- Tuberous sclerosis: *TSC1/TSC2* (chromosome 9q34/16p13), subependymal giant cell astrocytoma
- Neurofibromatosis type 1: NF1, chromosome 17q11, neurofibroma, optic nerve glioma, low-grade glioma
- Neurofibromatosis type 2: NF2, chromosome 22q12, schwannoma, meningioma, ependymoma
- Retinoblastoma: pRB, chromosome 13q, retinoblastoma
- Gorlin syndrome: PTCH, chromosome 9q31, desmoplastic medulloblastoma
- Hereditary nonpolyposis colorectal cancer (HNPCC): Mismatch repair deficiency, high-grade gliomas

RISK FACTORS: Exposure to ionizing radiation has been implicated in meningiomas, gliomas, and nerve sheath tumors. No convincing evidence has shown a link with trauma, occupation, cellular phone use, diet, or electromagnetic fields.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- In general, the location, size, and rate of growth will determine the symptoms and signs of a brain tumor.
- Headache is common and is the worst symptom in nearly half of all patients. The headaches are usually a dull, constant pain that is often worse at night. Symptoms of increased intracranial pressure may also be present, including nausea and vomiting, and may worsen with changes in body position that increase thoracic pressure (coughing, sneezing, Valsalva maneuver). Papilledema is suggestive of obstructive hydrocephalus.
- Seizures occur in 33% of patients and are among the most common symptoms, particularly with brain metastases and low-grade gliomas. The type of seizure and clinical presentation depend on the location of the brain tumor. Tumor-related seizures are typically repetitive and have similar presentation patterns. It is thought that patients with seizures typically have smaller tumors at the time of diagnosis compared with those with other symptoms, because the onset of seizures prompts an imaging study, leading to an earlier diagnosis.
- Focal neurologic signs and symptoms, including muscle weakness, sensory changes, or visual disturbances are also quite frequent. In addition, cognitive dysfunction, accompanied by changes in memory or personality change, may be recounted, often in retrospect.

ETIOLOGY

Most cases are idiopathic, though specific chromosomal abnormalities have been implicated in some tumor types.

TABLE 1 Frequency of Primary Central Nervous System Tumors

Children (0-14 Yr)		Adults (≥15 Yr)	
Type	**Percentage**	**Type**	**Percentage**
Glioblastoma	20	Glioblastoma	50
Astrocytoma	21	Astrocytoma	10
Ependymoma	7	Ependymoma	2

From Goetz CG, Pappert EJ: *Textbook of clinical neurology,* Philadelphia, 1999, WB Saunders.

DIAGNOSIS

- Diagnosis is typically based on clinical presentation and imaging characteristics. Specifically, neuroimaging is critical for preoperative planning and tumor etiology.
- Tumors are best seen on brain MRI with and without contrast; calcifications are sometimes present.
- Benign and low-grade tumors, typically in the glioma family, are heterogeneous and are generally seen as an infiltrating hemispheric lesion.

LABORATORY TESTS

- Ultimately, only histologic examination can provide the exact diagnosis. Additional features such as proliferative index, immunohistochemical stains, and electron microscopy can also be used to aid in diagnosis.
- The current classification schema for gliomas is based on molecular genetic and histologic criteria. Tumor histology/histologic diagnosis (World Health Organization [WHO] grading system) includes number of mitoses, capillary endothelial proliferation, and necrosis.
- Molecular genetic analysis of tumors is critical to classification of tumor type, stratification of treatments, and prognosis. Low-grade gliomas are divided into three categories based on molecular genetic findings based on the presence of an isocitrate dehydrogenase (IDH) mutation or 1p/19q codeletion. The presence of both a 1p/19q codeletion and an IDH mutation indicates an oligodendroglioma. A glioma with an IDH mutation but lacking an 1p/19q codeletion typically has *T53* and *ATRX* mutations and represents an astrocytoma. The other category of glioma lacks both an IDH mutation and a 1p/19q codeletion.

- A codeletion of 1p/19q bestows a favorable prognosis. Low-grade gliomas lacking an IDH mutation have a poor prognosis, one comparable to glioblastoma.
- However, even tumors with benign histology can cause significant morbidity due to their location and effect on surrounding structures.

DIFFERENTIAL DIAGNOSIS

- Stroke/cerebral hemorrhage
- Abscess/parasitic cyst
- Demyelinating disease: Multiple sclerosis, postinfectious encephalomyelitis
- Metastatic tumors
- Primary CNS lymphoma

WORKUP

Neuroimaging studies and pathologic sampling are the most important diagnostic modalities in evaluation of brain tumors and may be critical for preoperative planning.

IMAGING STUDIES

- MRI with gadolinium enhancement is highly sensitive and permits visualization of the tumor with relation to the surrounding tissue. Specifically, enhancing tumor can be distinguished from surrounding edema. Low-grade tumors often present as an infiltrating lesion without mass effect. MRI is superior to CT scanning for evaluating the meninges, subarachnoid space, and posterior fossa, and for defining relation to major intracranial vessels, although CT scanning is useful if calcification or hemorrhage is suspected (Fig. E1). Fig. E2 shows the appearance of astrocytoma in imaging studies.
- Magnetic resonance spectroscopy is increasingly being used as a diagnostic tool to help differentiate intracranial tumors from other intracranial processes using different chemical markers. For example, *N*-acetylaspartate is often decreased in brain tumors, whereas choline, a component of cell membranes, is often increased in brain tumors because of high cellular turnover.
- PET scan is helpful to distinguish neoplastic lesions (with high rate of metabolism) from other lesions such as demyelination or radiation necrosis (with a much lower metabolic rate). Such lesions take up greater amounts of glucose than surrounding tissues or tumors with slower metabolic rates. May be useful to help map functional areas of the brain before surgery or radiation.
- Functional MRI is now used as an adjunct in perioperative planning for patients whose lesion is in vital regions, such as those responsible for speech, language, and motor control.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Maximal surgical removal or debulking is the initial treatment of choice and provides tissue for diagnosis and molecular characterization. Maximal safe resection is often favored with a trend toward improved survival with this approach.
- Biopsy alone is performed if the tumor is located in eloquent regions of brain or is inaccessible; this is essential for histopathologic diagnosis. Biopsy can be performed under CT or MRI guidance using stereotactic localization.
- If the tumor is benign (e.g., meningioma, acoustic neuroma), often no further therapy is required.

ACUTE GENERAL Rx

Antiseizure medications have been used perioperatively and to control seizures resulting from focal lesions. Prophylactic use of anticonvulsants is not typically recommended without clear history of seizures.

CHRONIC Rx

- Chemotherapy (combination or single agent) may be used before, during, or after surgery and radiation therapy. In children, chemotherapy is often used to delay radiation therapy. A recent trial in patients with grade 2 glioma who were younger than 40 yr of age and had undergone subtotal tumor resection or who were 40 yr of age or older, progression-free survival and overall survival were longer among those who received combination chemotherapy in addition to radiation therapy than among those who received radiation therapy alone.[1]
- Radiation is useful for certain types of tumors and is often used if there is residual tumor after surgery; conventional radiation uses external beams over a period of weeks, whereas stereotactic radiosurgery delivers a single, high dose of radiation to a well-defined area (usually <1 cm). Long-term effects of radiation therapy include radiation necrosis (particularly of white matter), blood vessel hyalinization, and secondary tumors (usually meningiomas, sarcomas, and malignant astrocytomas). Radiosensitizers may help increase the therapeutic effect of radiation therapy.
- Experimental therapies are continually in development and target molecular characterization of tumors and small molecule blockers of signal transduction cascades involved in tumor growth. Some of these therapies involve antisense molecules, biologic agents, immunotherapies, or angiogenesis inhibitors. Intratumoral drug infusions and convection-enhanced delivery of novel agents are currently under study.

[1] Buckner JC et al: Radiation plus procarbazine, CCNU, and vincristine in low-grade glioma, *N Engl J Med* 374:1344-1355, 2016.

DISPOSITION

In general, younger age, high performance status, lower pathologic grade, the presence of an IDH mutation, and a 1p/19q codeletion have more favorable prognosis. For all histologic subtypes of brain tumors, pediatric and young adult patients have a better survival rate.

REFERRAL

- All cases warrant evaluation by an oncologist and neurosurgeon. Referral to a neurologist is indicated for management of seizures and headaches related to the tumor.
- Patients should be evaluated for physical and occupational therapy.
- Children should undergo neuropsychologic evaluations and screening for learning disabilities.

! PEARLS & CONSIDERATIONS

COMMENTS

Molecular genetic characterization is important for diagnosis, therapeutic approach, and prognosis, for which mutations in IDH and the presence of a 1p/19q codeletion represented some of the critical genetic determinations. In general, younger age, high performance status, and lower pathologic grade have more favorable prognosis. For all histologic subtypes of brain tumors, pediatric and young adult patients have a better survival.

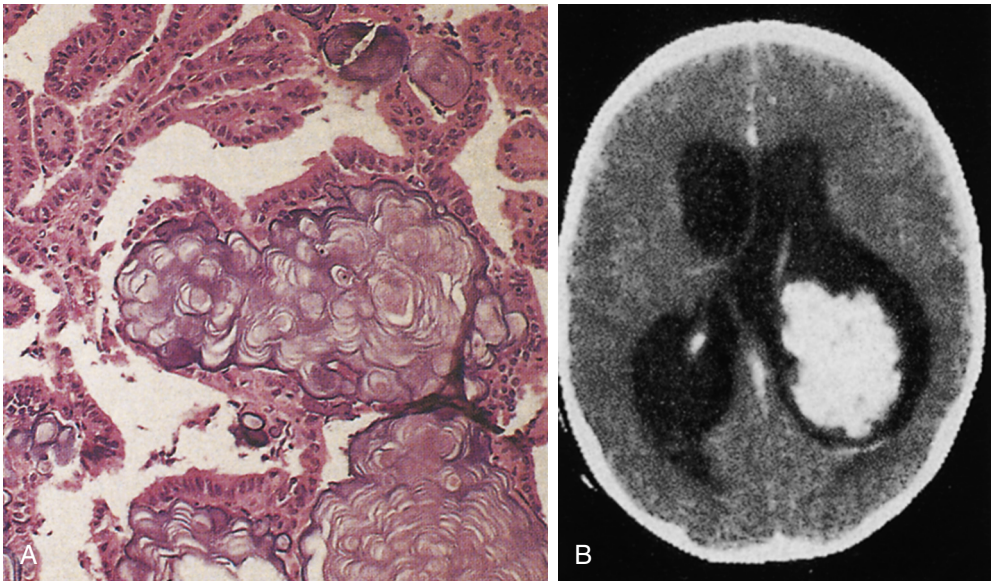

FIG. E1 Choroid plexus papilloma. A, Calcification is common both in normal aging choroid plexus and in choroid plexus papillomas and is associated with **B,** hyperdensity on computed tomography scan. (From Skarin AT: *Atlas of diagnostic oncology*, ed 4, Philadelphia, 2010, Mosby.)

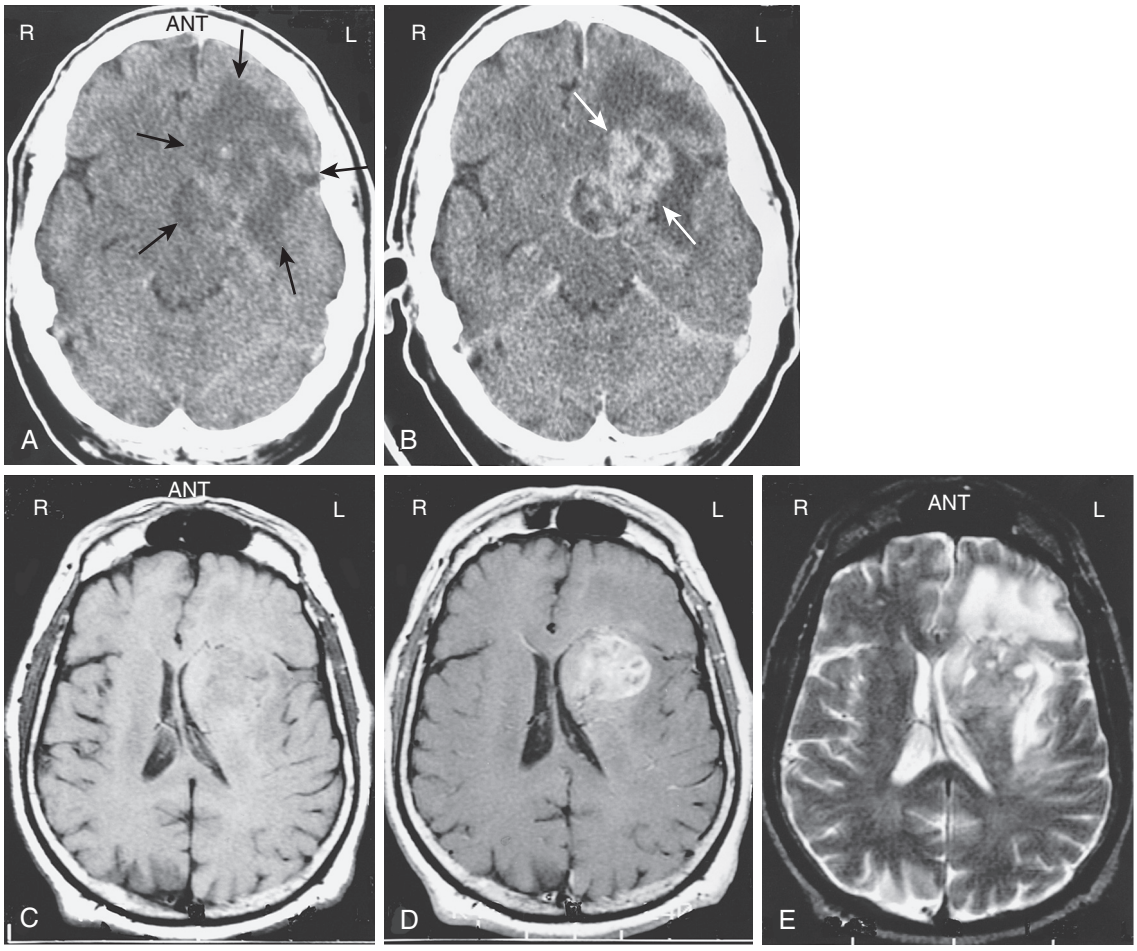

FIG. E2 Astrocytoma. These contrasted and noncontrasted computed tomography (CT) and magnetic resonance (MR) images were obtained from the same patient and demonstrate a left astrocytoma with a large amount of surrounding edema. The noncontrasted CT scan **(A)** shows only a large area of low density that represents the tumor and edema *(arrows).* A contrasted CT scan **(B)** shows enhancement of the tumor *(arrows)* surrounded by the dark or low-density area of edema. A noncontrasted T1 MR image **(C)** clearly shows a mass effect due to impression of the tumor on the left lateral ventricle and some midline shift. A gadolinium-enhanced T1 MR image **(D)** clearly outlines the tumor, but the edema is difficult to see. A T2 MR image **(E)** shows the tumor rather poorly, but the surrounding edema is easily seen as an area of increased signal *(white).* (From Mettler FA Jr: *Essentials of radiology,* ed 3, Philadelphia, 2014, Elsevier.)

BASIC INFORMATION

DEFINITION

Glioblastoma (GBM) is the most aggressive diffuse glioma of astrocytic lineage and corresponds to grade IV in the World Health Organization's (WHO) classification system. GBM is the most common brain and central nervous system (CNS) malignancy, accounting for 45.2% of malignant primary brain and CNS tumors, 54% of all gliomas, and 16% of all primary brain and CNS tumors.

GBM represents a molecularly heterogeneous disease with numerous subclassifications. GBMs comprise primary and secondary subtypes that evolve through different genetic pathways, affect patients at different ages, and have differences in outcomes. Primary (*de novo*) GBMs account for 80% of GBMs and occur in older patients (mean age 62 yr). Secondary GBMs develop from lower-grade astrocytomas or oligodendrogliomas and occur in younger patients (mean age 45 yr).

ICD-10CM CODE

C71.9 Malignant neoplasm of brain, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Based on the 2014 CBTRUS report, the average annual age-adjusted incidence rate (IR) of GBM is 3.19/100,000 population.

PREDOMINANT SEX AND AGE: GBM is primarily diagnosed at older ages, with the median age of diagnosis at 64 yr. It is uncommon in children, accounting for ~3% of all brain and CNS tumors reported among infants to 19-yr-olds. A higher incidence of GBM has been reported in men compared with women; the incidence rate is 1.6 times higher in males [3.97 vs. 2.53]. Whites have the highest incidence rates for GBM compared with any other race in the U.S.

RISK FACTORS: Many genetic and environmental factors have been studied in GBM, but no risk factor that accounts for a large proportion of GBM has been identified. Like many cancers, the causes are sporadic. Factors associated with GBM risk are prior therapeutic radiation, decreased susceptibility to allergy, immune factors and immune genes, and some single nucleotide polymorphisms (SNPs) detected by genome-wide association studies (GWAS). There is no substantial evidence of GBM association with lifestyle characteristics such as cigarette smoking, alcohol consumption, drugs, or dietary exposure to N-nitroso compounds (cured or smoked meat or fish). Inconsistent and nondefinitive results have been published regarding the risk of glioma with use of mobile phones.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients present with a variety of symptoms, including headache, seizures, symptoms of increased intracranial pressure, and cognitive disturbances.

DIAGNOSIS

IMAGING STUDIES

Initial workup includes imaging studies. Brain MRI with and without contrast is the study of choice, and demonstrates a contrast-enhancing tumor. Functional MRI is now used as an adjunct modality in perioperative planning for patients whose lesion is in vital regions (eloquent regions), such as those responsible for speech, language, and motor control. Pathologically, GBM is a high-grade astrocytoma characterized by hypercellularity, mitotic activity, nuclear atypia, pseudopalisading necrosis, and microvascular proliferation. Various molecular markers have been identified distinguishing GBM from other lower grade astrocytomas, as well as differentiating primary and secondary subtypes of GBM.

TREATMENT

- GBM is an aggressive neoplasm with a median survival of 3 mo if untreated.
- Combined modality therapy with surgery, RT, and chemotherapy has significantly improved survival of GBM patients. Treatment is complex and initially consists of maximal-safe surgical resection followed by RT with concurrent temozolomide (TMZ) chemotherapy followed by six cycles of maintenance TMZ with tumor-treating fields.
- Surgical intervention has decompressive and cytoreductive effects, and there is increasing evidence of a significant survival advantage with complete resection.
- Various emerging treatment modalities under investigation seem promising, including immunotherapy. Regression of glioblastoma after chimeric antigen receptor T-cell therapy has been reported (see Brown CE et al, in Suggested Readings). Intratumoral infusion of recombinant nonpathogenic polio-rhinovirus chimera (PVSRIPO) has improved survival rate in advanced stage glioblastoma (see Desjardins et al in Suggested Readings).
- Symptomatic treatment includes corticosteroids to reduce cerebral edema, antiepileptic drugs for seizures, and painkillers for headache.

REFERRAL

Treatment involves a multidisciplinary team approach including oncology, neurosurgery, neurology, and radiation oncology.

PROGNOSIS

Survival: GBM has a poor prognosis with a low relative survival estimate; only a few patients reach long-term survival status of 2.5 yr, and less than 5% of patients survive 5 yr post-diagnosis. The relative survival for the first yr after diagnosis is 35%, falls in the second yr post-diagnosis to 13.7%, and continues to fall thereafter. Median survival of GBM post-diagnosis is 15 mo following standard therapy. Several variables affect the prognosis of GBM patients, including age, preoperative performance status, tumor location, preoperative imaging characteristics of the tumor, and the extent of resection.

Prognostic molecular markers in GBM: All GBMs are WHO grade IV but exhibit significant genetic heterogeneity. Tumor subtypes, based on genetic alterations, exist within this larger homogeneous histologic category and carry prognostic significance. These markers include methylation status of the gene promoter for O^6-methylguanine-DNA methyltransferase (MGMT), isocitrate dehydrogenase enzyme 1/2 *(IDH1/2)* mutation, epidermal growth factor receptor (EGFR) overexpression and amplification, tumor protein *(TP53)* mutation, *ATRX* mutation and genetic losses of chromosomes.

- Primary GBMs show EGFR overexpression, phosphatase and tensin homolog gene (*PTEN*) mutations, and loss of heterozygosity (LOH) 10q, p16 deletions; less frequently shown are mouse double-minute 2 (MDM2) amplification, high frequency of telomerase reverse transcriptase (hTERT) promoter mutations, and absence of *IDH1* mutation.
- The hallmark of secondary GBMs is *TP53,* alpha thalassemia/mental retardation syndrome X-linked *(ATRX)* and *IDH1* mutations; additionally, they show LOH 10q.
- The MGMT promoter is methylated in approximately 50% of newly diagnosed GBMs. MGMT methylation is more common in secondary than primary GBM (75% vs. 36%, respectively) and has prognostic and predictive significance of better overall survival in patients with GBM, irrespective of treatment choices.
- *IDH1/2* mutations are far more common in grades II and III astrocytomas and oligodendrogliomas compared with GBMs, and more than 90% of the mutations involve *IDH1. IDH1/2* mutations are a selective molecular marker of secondary GBMs, help distinguish them from primary GBMs, and are a marker of more favorable prognosis in high-grade gliomas.
- In GBMs, EGFR signaling promotes cell division, tumor invasiveness, and resistance to radiation therapy (RT) and chemotherapy. About 40% of all GBMs have EGFR amplification, and it is more common in primary as compared with secondary GBMs.
- Mutation of the *TP53* gene has been found in 60% to 70% of secondary GBMs and 25% to 30% of primary GBMs, and it occurs more frequently in younger patients. Studies of *TP53* mutations as a prognostic marker have not been definitive.
- *ATRX* is frequently mutated in grade II-III astrocytomas (71%), oligoastrocytomas (68%), and secondary GBMs (57%), but is infrequent in primary (4%) and pediatric GBMs (20%) as well as pure oligodendroglial tumors (14%). In a prospective cohort of patients with astrocytic tumors, those harboring *ATRX* loss had a significantly better prognosis than the ones that expressed *ATRX* and had IDH mutation.
- *TERT* mutation is one of the most frequent genetic alterations in primary adult GBMs and is significantly higher in these tumors as compared with secondary adult or any pediatric GBMs. GBMs with *TERT* mutation have a shorter survival than those without *TERT* mutations. However, when adjusted for GBM subtype (primary and secondary), they do not have a significant impact on survival.

Breast Abscess PTG

BASIC INFORMATION

DEFINITION

Breast abscess is an acute inflammatory process resulting in the formation of a collection of purulent material (pus) in breast tissue. Typically, there is painful, erythematous mass formation in the breast, occasionally draining through the overlying skin or nipple duct.

SYNONYMS

Subareolar abscess
Lactational or puerperal abscess

ICD-10CM CODES

O91.111	Abscess of breast associated with pregnancy, first trimester
O91.112	Abscess of breast associated with pregnancy, second trimester
O91.113	Abscess of breast associated with pregnancy, third trimester
O91.119	Abscess of breast associated with pregnancy, unspecified trimester
O91.12	Abscess of breast associated with the puerperium
O91.13	Abscess of breast associated with lactation

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 10% to 30% of all breast abscesses are lactational; acute mastitis occurs in 10% of nursing mothers, with one in 15 of these women developing abscess. A recent Cochrane review, however, found that as many as 30% of nursing mothers may have evidence of mastitis. Smoking, obesity, and diabetes may be risk factors for nonpuerperal mastitis with abscess. More recently, nipple piercing may also be associated with infection.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Painful, erythematous induration involving breast and leading to fluctuant, possibly palpable abscess
- Systemic symptoms: Fever and malaise

ETIOLOGY

- Lactational abscess: Milk stasis and bacterial infection leading to mastitis and then abscess, with *Staphylococcus aureus* (commonly MRSA) the most common causative agent
- Subareolar abscess:
  1. Central ducts involved, with obstructive nipple duct changes leading to bacterial infection
  2. Cultured organisms mixed, including anaerobes, staphylococci, streptococci, and others

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory carcinoma
- Advanced carcinoma with erythema, edema, and/or ulceration
- Tuberculous abscess (rare in the U.S.)
- Hidradenitis of breast skin
- Sebaceous cyst with infection

WORKUP

- Clinical examination. Fig. 1 illustrates the various areas where breast abscesses can develop
- Ultrasound to identify fluid collection, which can be used to guide treatment options
- If abscess suspected, referral to surgeon for incision, drainage, and biopsy

LABORATORY TESTS

- Perform culture and sensitivity test of abscess contents.
- If mammogram or ultrasound is required but prevented by discomfort, perform after treatment and subsequent resolution of abscess.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Established abscess: Incision and drainage vs. needle aspiration
- Biopsy of abscess cavity wall to exclude carcinoma

ACUTE GENERAL Rx

- Antibiotics: Generally staphylococci (*S. aureus)* in lactational abscess. Recommended initial antibiotic therapy is nafcillin or oxacillin 2 g q4h IV or cefazolin 1 g q8h IV for 10 to 14 days. Alternative includes vancomycin 1 g IV q12h.
- If acute mastitis is identified and treated early without the development of an abscess, resolution without drainage is possible.
- Subareolar abscess: Broad-spectrum antibiotic treatment (e.g., cephalexin 500 mg PO qid or cefazolin 1 g q8h IV for 10 to 14 days for more severe infection) and drainage (Fig. 1) are needed to control acute phase. If abscess is odoriferous, consider anaerobes as most likely etiology and add metronidazole 500 mg PO/IV tid.

CHRONIC Rx

Further surgical treatment for recurrences or fistula

DISPOSITION

- Lactational abscess: Possible to continue breastfeeding without risk of infection to the infant
- Subareolar abscess:
  1. High risk for recurrence or complication of fistula formation
  2. Patient informed and referred to General Surgery for evaluation and treatment

REFERRAL

- If abscess drainage required.
- If subareolar abscess involved, refer to surgery.

Breast Cancer (Related Key Topic)
Mastodynia (Related Key Topic)

AUTHOR: **Anthony Sciscione, DO**

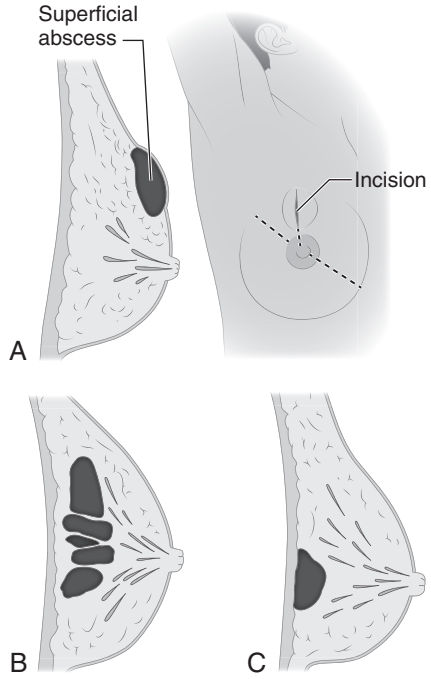

FIG. 1 A, A superficial breast abscess may be drained with a linear incision that radiates from the nipple. **B** and **C,** Diagrams of intramammary abscess **(B)** and retromammary abscess **(C)**. Both require drainage under general anesthesia. The abscess itself may not be fully appreciated if it is deep seated, and the mistaken diagnosis of cellulitis may be made. (Redrawn from Wolcott MW: *Ferguson's surgery of the ambulatory patient*, 5th ed, Philadelphia, 1974, JB Lippincott. Reprinted with permission.)

BASIC INFORMATION

DEFINITION

Breast cancer refers to both in situ and invasive carcinoma of the breast. Breast cancer can be of either ductal or lobular types.

SYNONYM

Carcinoma of the breast

ICD-10CM CODES

C50.911	Malignant neoplasm of unspecified site of right female breast
C50.912	Malignant neoplasm of unspecified site of left female breast
C50.919	Malignant neoplasm of unspecified site of unspecified female breast
C50.921	Malignant neoplasm of unspecified site of right male breast
C50.922	Malignant neoplasm of unspecified site of left male breast
C50.929	Malignant neoplasm of unspecified site of unspecified male breast

EPIDEMIOLOGY & DEMOGRAPHICS

- In the U.S., there will be an estimated 271,270 new patients and an estimated 42,260 deaths in 2019.
- The most common form of breast cancer is hormone-receptor positive; its incidence has increased particularly among young women. Breast cancer is nearly exclusively the disease of women, with only 1% of breast cancers occurring in males.
- Table 1 enumerates risk factors for breast cancer.
- Genetically defined group of women with *BRCA1* or *BRCA2* genes identified to carry lifetime risk as high as 85%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Increasing number of small breast cancers are found by mammograms in which case patients are usually completely free of symptoms or physical findings.
- Palpable lump or mass which can be self-detected or physician-detected.
- Skin and/or nipple retraction and skin edema, erythema, ulcer, satellite nodule.
- Nodal enlargement in axilla and supraclavicular areas.
- Nipple discharge may be serous or bloody.
- Generalized symptoms and signs, including fatigue, weight loss, jaundice, and anorexia, may be present in metastatic cases.

ETIOLOGY

- The precise mechanism of carcinogenesis is not understood. Endogenous and exogenous estrogen exposure is key to the development of receptor-positive breast cancer.
- Breast cancer is no longer perceived as a single disease. Molecular classification based on gene expression profiling has shown breast cancer to be of the following types:
  1. Luminal A type: Endocrine responsive with favorable prognosis.
  2. Luminal B type: Endocrine responsive with less favorable prognosis.
  3. Normal type: Resemble normal epithelium and prognosis similar to luminal B type.
  4. *HER2* amplified type: *HER2* gene amplification.
  5. Basal type: Hormone receptor and *HER2* negative cancers with poor prognosis.
- Approximately 10% of all women with breast cancer have a germline mutation of *BRCA1, BRCA2, P53*, or other mutations.
- Possibly interaction of ovarian estrogen, non-ovarian estrogen, estrogens of exogenous origin with breast tissue of varied carcinogenic susceptibility to develop cancer.
- Other known or suspected variables: Childbearing, breastfeeding practice, diet, physical activity, body mass, alcohol intake.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Benign disease is summarized in Table 2. The following nonmalignant breast lesions can simulate breast cancer on both physical and mammogram examinations:

- Fibrocystic changes
- Fibroadenoma
- Hamartoma

TABLE 1 Risk Factors for Breast Cancer

Risk Factor	Relative Risk
Any benign breast disease	1.5
Postmenopausal hormone replacement	1.5
Menarche at <12 yr	1.1-1.9
Moderate alcohol intake (2-3 drinks/day)	1.1-1.9
Menopause at >55 yr	1.1-1.9
Increased bone density	1.1-1.9
Sedentary lifestyle and lack of exercise	1.1-1.9
Proliferative breast disease without atypia	2
Age at first birth >30 yr or nulliparous	2-4
First-degree relative with breast cancer	2-4
Postmenopausal obesity	2-4
Upper socioeconomic class	2-4
Personal history of endometrial or ovarian cancer	2-4
Significant radiation to chest	2-4
Increased breast density on mammogram	2-4
Older age	>4
Personal history of breast cancer (in situ or invasive)	>4
Proliferative breast disease with atypia	>4
Two first-degree relatives with breast cancer	5
Atypical hyperplasia and first-degree relative with breast cancer	10

(From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.)

WORKUP

- Initial workup:
  1. Mass assessment by medical professional.
  2. Diagnostic mammogram followed by breast ultrasound for suspicious lesions.
  3. MRI (Fig. 1) may detect suspicious lesions better than mammography alone in women with dense breasts or inherited predisposition to breast cancer.
  4. Table 3 summarizes guidelines for evaluation and treatment of nonpalpable ductal carcinoma in situ.
- Diagnosis:
  1. Positive aspiration cytology on a clinically and mammographically suspicious mass is highly accurate, but it requires open biopsy confirmation.
  2. Stereotactic, ultrasound-guided core-needle biopsy procedures are accurate and have low complication rates. Indications for stereotactic core biopsy are summarized in Box 1. Box 2 describes contraindications to stereotactic core biopsy.
  3. Excisional surgical biopsy establishes diagnosis.
- Breast radiologic evaluation and an algorithm for breast cancer screening and evaluation are described in Section III. The differential diagnosis of breast lumps is described in Section II.

TABLE 2 American Board of Pathology Histologic Classification of Benign Disease

Histopathologic Findings	Approximate Relative Risk
Nonproliferative	No added risk
Cysts	
Duct ectasia	
Calcification	
Fibroadenoma	
Milk ductal epithelial hyperplasia	
Sclerosing adenosis	No added risk
Papillomatosis	Slight added risk
Radial scars	
Complex sclerosing lesions	?
Moderate florid hyperplasia	1.5:1-2:1
Atypical hyperplasia (ductal and lobular)	4:1
Extensive ductal involvement of atypical hyperplasia	7:1
Lobular carcinoma in situ	10:1
Ductal carcinoma in situ	10:1

(From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

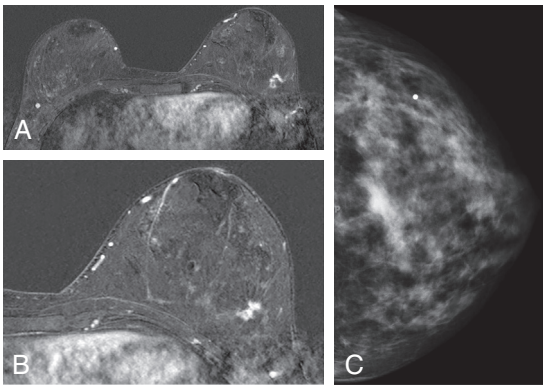

FIG. 1 A 42-yr-old woman with *BRCA2* mutation. Magnetic resonance imaging (MRI) screening showed a 1.2-cm invasive ductal cancer in the lower outer left breast seen only on MRI **(A** and **B)** and subsequently on second-look ultrasound. **C,** The mammogram showed only dense breast tissue. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

TABLE 3 Guidelines for Evaluation and Treatment of Nonpalpable Ductal Carcinoma In Situ

1. Careful multiview mammography with or without ultrasound and including magnification views
   - Document extent of disease
   - Identify other areas of microcalcification
2. Suspicious microcalcifications and densities cleared with needle localization biopsy
3. Specimen radiography with magnification techniques
4. Radiograph-directed histopathologic evaluation with orientation of specimen by surgeon using multicolored inked margins
5. Complete pathologic description to include:
   - Type of DCIS and size of tumor
   - Relation to microcalcifications
   - Distance of lesion from inked margins
   - Presence of multifocality
   - Presence or risk of microinvasion
6. Repeat mammography with magnification to confirm successful clearing of suspicious areas
7. Repeat breast excision if:
   - Residual microcalcifications are found
   - Margins are unacceptable

DCIS, Ductal carcinoma in situ.
(From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

BOX 1 Indications for Stereotactic Core Biopsy

- Certain probably benign lesions, BI-RADS 3, depending on clinical suspicion, patient or physician preference, or when short-term follow-up is not practical
- Lesions suspicious, BI-RADS 4
- Lesions highly suspicious, BI-RADS 5
- New suspicious microcalcifications, developing asymmetries, or architectural distortions
- Nonpalpable asymmetry, focal asymmetry, or solid mass on mammogram not seen on ultrasound
- Mammographic lesions corresponding to suspicious areas of enhancement on MRI

BI-RADS, Breast Imaging-Reporting and Data System; *MRI,* magnetic resonance imaging.
(From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

BOX 2 Contraindications to Stereotactic Core Biopsy

- Patient unable to lie prone or cooperate
- Patient's weight
- Lesion location near nipple, too superficial to skin, or too posterior to chest wall
- Lesion mammographically occult
- Patient has severe kyphosis or movement disorders
- Lack of breast tissue thickness for adequate compression

(From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

STAGING

Table 4 describes the pathologic staging of breast cancer.

IMAGING STUDIES

Mammograms (Fig. E2, Fig. E3): 30% to 50% of breast cancers are detected by screening mammograms as a spiculated mass, a mass with or without microcalcifications, or a cluster of microcalcifications. MRI is a modality that is particularly useful in patients with breast implants and when there is a strong family history of breast cancer. MRI is also better for assessing the response to neoadjuvant chemotherapy and is useful in identifying the primary tumor in patients who present with axillary adenopathy.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- These approaches include various types of surgical resection and reconstruction as well as adjuvant radiotherapy.
- For early breast cancer, the primary therapy is typically surgical. The choice is between modified radical mastectomy and breast-conserving treatment, which consists of lumpectomy, axillary staging with sentinel node biopsy, or axillary dissection.
- Table 5 compares ductal versus lobular carcinoma in situ. Adjuvant treatment guidelines for patients with early-stage invasive breast cancer are described in Table 6.
- Among patients with limited sentinel lymph nodes (SLN) who are treated with breast conservation and systemic therapy, sentinel lymph node dissection (SLND) alone compared with axillary lymph node dissection (ALND) did not result in inferior survival.
- DCIS: Local breast-conserving therapy (lumpectomy plus radiation therapy) or mastectomy followed by endocrine therapy in estrogen receptor-positive cases.
- Invasive breast cancer: Mastectomy or lumpectomy, along with sentinel lymph node evaluation followed by radiation therapy for large tumors.
- Invasive breast cancer may require adjuvant endocrine therapy and chemotherapy. Endocrine therapy is recommended alone or after chemotherapy in patients with hormone-receptor positive tumors. Breast cancer intrinsic subtypes are summarized in Table 7. Treatment according to breast cancer subtypes is described in Table 8. Adjuvant hormone therapy with antiestrogen drugs reduces disease recurrence and mortality in women with breast cancer. Aromatase inhibitors (anastrozole, letrozole, exemestane, fulvestrant) decrease the agonist effect of estrogen by inhibiting estrogen synthesis and have become preferred first-line hormonal treatment agents over the selective estrogen receptor modulator tamoxifen.
- Standard *adjuvant chemotherapy* regimens in current use in the U.S. include AC (cyclophosphamide plus doxorubicin), AC-T (doxorubicin and cyclophosphamide followed by a taxane),

TABLE 4 Pathological Staging of Breast Cancer

T_X	Primary tumor cannot be assessed
T_0	No evidence of primary tumor
T_{is}	Carcinoma in situ
T_{is} (DCIS)	Ductal carcinoma in situ
T_{is} (LCIS)	Lobular carcinoma in situ
T_{is} (Paget)	Paget disease of the nipple NOT associated with invasive carcinoma and/or carcinoma in situ (DCIS and/or LCIS) in the underlying breast parenchyma. Carcinomas in the breast parenchyma associated with Paget disease are categorized based on the size and characteristics of the parenchymal disease, although the presence of Paget disease should still be noted
T_1	Tumor ≤20 mm in greatest dimension
T_{1mi}	Tumor ≤1 mm in greatest dimension
T_{1a}	Tumor >1 mm but ≤5 mm in greatest dimension
T_{1b}	Tumor >5 mm but ≤10 mm in greatest dimension
T_{1c}	Tumor >10 mm but ≤20 mm in greatest dimension
T_2	Tumor >20 mm but ≤50 mm in greatest dimension
T_3	Tumor >50 mm in greatest dimension
T_4	Tumor of any size with direct extension to the chest wall and/or to the skin (ulceration or skin nodules)
T_{4a}	Extension to chest wall, not including only pectoralis muscle adherence/invasion
T_{4b}	Ulceration and/or ipsilateral satellite nodules and/or edema (including peau d'orange) of the skin, which do not meet the criteria for inflammatory carcinoma
T_{4c}	Both T_{4a} and T_{4b}
T_{4d}	Inflammatory carcinoma
N_X	Regional lymph nodes cannot be assessed (e.g., previously removed)
N_0	No regional lymph node metastasis
N_1	Metastasis to movable ipsilateral level I, II axillary lymph node(s)
N_2	Metastases in ipsilateral level I, II axillary lymph nodes that are clinically fixed or matted or in clinically detected ipsilateral internal mammary nodes in the *absence* of clinically evident axillary lymph node metastasis
N_{2a}	Metastases in ipsilateral level I, II axillary lymph nodes fixed to one another (matted) or to other structures
N_{2b}	Metastases only in clinically detected ipsilateral internal mammary nodes and in the *absence* of clinically evident level I, II axillary lymph node metastases
N_3	Metastases in ipsilateral infraclavicular (level III axillary) lymph node(s), with or without level I, II axillary node involvement, or in clinically detected ipsilateral internal mammary lymph node(s) and in the *presence* of clinically evident level I, II axillary lymph node metastasis; or metastasis in ipsilateral supraclavicular lymph node(s), with or without axillary or internal mammary lymph node involvement
N_{3a}	Metastasis in ipsilateral infraclavicular lymph node(s)
N_{3b}	Metastasis in ipsilateral internal mammary lymph node(s) and axillary lymph node(s)
N_{3c}	Metastasis in ipsilateral supraclavicular lymph node(s)
M_0	No clinical or radiographic evidence of distant metastasis
$cM_{0(i+)}$	No clinical or radiographic evidence of distant metastases, but deposits of molecularly or microscopically detected tumor cells in circulating blood, bone marrow, or other nonregional nodal tissue that are no larger than 0.2 mm in a patient without symptoms or signs of metastases
M_1	Distant detectable metastases as determined by classic clinical and radiographic means and/or histologically proven >0.2 mm
G_X	Grade cannot be assessed
G_1	Low combined histologic grade (favorable)
G_2	Intermediate combined histologic grade (moderately favorable)
G_3	High combined histologic grade (unfavorable)

Stage Groupings in Breast Cancer

Stage	T	N	M
0	T_{is}	N_0	M_0
I_A	T_1	N_0	M_0
I_B	T_0-T_1	N_{1mi}	M_0
II_A	T_0-T_1	N_1	M_0
	T_2	N_0	M_0
II_B	T_2	N_1	M_0
	T_3	N_0	M_0
III_A	T_0-T_2	N_2	M_0
	T_3	N_1-N_2	M_0
III_B	T_4	N_0-N_2	M_0
III_C	Any T	N_3	M_0
IV	Any T	Any N	M_1

(From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.) (AJCC 8th ed., 2018)

and TC (docetaxel and cyclophosphamide). Fig. E4 illustrates considerations for adjuvant chemotherapy in breast cancer.

- *Neoadjuvant chemotherapy* (same regimens as used in the adjuvant setting) results in pathologic complete responses in significant number of cases, causes downstaging, provides an assessment of chemosensitivity, and provides no deleterious effect on survival.
- The benefit of adjuvant chemotherapy or hormone therapy can be assessed by commercially available *multigene assays* (OncotypeDx, Mammaprint) that have demonstrated utility in determining prognostic and predictive benefit with both hormonal therapy and chemotherapy in breast cancer. Recently published results from the prospective TAILORx trial support the routine use of multigene assays so as to identify intermediate-risk score patients in which chemotherapy can be safely omitted.
- *Metastatic breast cancer* is approached based on the extent of bone-only or visceral disease sites as well as the rate of symptomatic progression. Typically, bone-only metastatic disease is approached with upfront, sequential hormonal therapy. The combination of mTOR inhibitors (everolimus) or CDK4/CDK6 inhibitors (palbociclib, ribociclib, abemaciclib) with aromatase inhibitors has been associated with improved overall survival. Among patients with *PIK3CA*-mutated, hormone-receptor-positive, *HER2*-negative advanced breast cancer who had received endocrine therapy previously, treatment with the combination of alpelisib plus fulvestrant prolonged progression-free survival, leading to the approval of this combination approach. Commonly used cytotoxic chemotherapy and anti-*HER2* therapy drugs in metastatic breast cancer are summarized in Table 9.
- Patients with progressive bone disease or those with visceral disease are treated with typically single-agent chemotherapy and occasionally with combination chemotherapy regimens. The chemotherapy agents are the same as those used in early stages of disease. Sequential chemotherapy with different classes of chemotherapy agents are usually used to provide palliation with improvement in survival and symptoms.
- Patients whose tumors have germline *BRCA1*/2 mutations can be treated with the PARP inhibitors olaparib or talazoparib.
- Patients with triple-negative breast cancer whose tumors express the program death ligand-1 receptor derive a survival benefit with the use of the combination of albumin-bound paclitaxel and the immune inhibitor atezolizumab.
- In patients with metastatic *HER2/neu*-positive breast cancer, the addition of the monoclonal antibody pertuzumab to the standard regimen of trastuzumab and docetaxel significantly improves the median overall survival. Also, the antibody-drug conjugate TDM-1 improves survival in this group of patients.

TABLE 5 Carcinoma In Situ: Lobular Versus Ductal

Feature	Lobular Carcinoma In Situ	Ductal Carcinoma In Situ
Age	Younger	Older
Palpable mass	No	Uncommon
Mammographic appearance	Not detected on mammography	Microcalcifications, mass
Immunophenotype	E-cadherin negative	E-cadherin positive
Usual manifestation	Incidental finding on breast biopsy	Microcalcifications on mammography or breast mass
Bilateral involvement	Common	Uncertain
Risk and site of subsequent breast cancer	25% risk for invasive breast cancer in either breast over remaining lifespan	At site of initial lesion; 0.5% risk/yr of invasive breast cancer in opposite breast
Prevention	Consider tamoxifen or raloxifene	Consider tamoxifen or raloxifene if estrogen-receptor positive
Treatment	Yearly mammography and breast examination	Lumpectomy ± radiation; mastectomy for large or multifocal lesions

(From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.)

TABLE 6 Adjuvant Treatment Guidelines for Patients with Early-Stage Invasive Breast Cancer

Patient Group	Treatment
Hormone Receptor-Positive and *HER2* Positive Breast Cancer	
<0.5 cm	Consider adjuvant endocrine therapy
0.6-1 cm	Adjuvant endocrine therapy Consider adjuvant chemotherapy and trastuzumab
>1 cm	Adjuvant endocrine therapy Adjuvant chemotherapy and trastuzumab
Node positive	Adjuvant endocrine therapy Adjuvant chemotherapy with pertuzumab and trastuzumab
Hormone Receptor-Positive and *HER2* Negative Breast Cancer	
<0.5 cm	No adjuvant therapy
>0.5 cm	Adjuvant hormonal therapy Consider adjuvant chemotherapy based on 21-gene recurrence score
Node-positive	Adjuvant hormonal therapy + adjuvant chemotherapy
Hormone Receptor-Negative and *HER2* Positive Breast Cancer	
<0.5 cm	Consider adjuvant chemotherapy and trastuzumab
0.6-1 cm	Consider adjuvant chemotherapy and trastuzumab
>1 cm	Adjuvant chemotherapy and trastuzumab
Node positive	Adjuvant endocrine therapy Adjuvant chemotherapy with pertuzumab and trastuzumab
Hormone Receptor-Negative and *HER2* Negative Breast Cancer	
≤0.5 cm	No adjuvant therapy
0.6-1.0 cm	Consider adjuvant chemotherapy
>1 cm or node positive	Adjuvant chemotherapy

HER2, human epidermal growth factor receptor 2.
(Modified from National Comprehensive Cancer Network Guidelines. Available at www.nccn.org.)

CHRONIC Rx

Follow-up after treatment of early breast cancer stages includes:

- Regular clinical evaluations as delineated by medical oncologist or surgeon.
- Annual mammograms and breast MRI as indicated.
- Laboratory tests as indicated.
- Tumor markers and CT scans for surveillance are not recommended.
- Patient instruction in monthly breast self-examination.
- Prognosis after curative therapy: Depends on size of tumor, extent of nodal metastasis, and pathologic grade of tumor.
- Systemic adjuvant therapy: Improves prognosis significantly. Women who take tamoxifen for 10 yr lower their recurrence risk by 25% and their dying of breast cancer risk by 27% compared with those who took it for just 5 yr. Adjuvant therapy with an aromatase inhibitor improves survival outcomes, compared with tamoxifen, in postmenopausal women with hormone receptor–positive breast cancer. Recent trials have shown that in premenopausal women with hormone receptor–positive early breast cancer, adjuvant treatment with the aromatase inhibitor exemestane plus ovarian suppression, compared with tamoxifen plus ovarian suppression, significantly reduced recurrence.
- Isolated tumor cells or micrometastases in regional lymph nodes are associated with a reduced 5-yr rate of disease-free survival among women with favorable early-stage breast cancer who do not receive adjuvant therapy. Survival is improved in patients with isolated tumor cells or micrometastases who received adjuvant therapy.
- Retrospective analyses suggest that occult lymph-node metastases are an important prognostic factor for disease recurrence or survival among patients with breast cancer; however, recent trials indicate that the magnitude of the difference in outcome at 5 yr is small (1.2 percentage points). These data do not favor a clinical benefit of additional evaluation (including immunohistochemical analysis) of initially negative sentinel nodes in patients with breast cancer.
- The addition of zoledronic acid to adjuvant endocrine therapy improves disease-free survival in premenopausal patients with estrogen-responsive early breast cancer.

REFERRAL

Referral to a multidisciplinary team consisting of a breast surgeon, reconstructive surgeon, medical oncologist, and radiation oncologist is necessary as soon as breast cancer is suspected.

PEARLS & CONSIDERATIONS

BREAST CANCER IN PREGNANCY AND LACTATION

- Frequency in women 40 yr or younger reported to be 15%
- May carry worse prognosis because disease discovery delayed by engorged and nodular breast changes and/or because disease progression more rapid in pregnancy
- Survival rates similar to those for nonpregnant early-stage patients in same age group
- Expedient workup recommended, including mammography and sonography
- Choice of mastectomy or lumpectomy with axillary dissection for treatment
- Adjuvant chemotherapy delayed until third trimester or after delivery
- Irradiation to breast after lumpectomy delayed until after delivery

DUCTAL CARCINOMA IN SITU (DCIS, INTRADUCTAL CARCINOMA) (SEE TABLE 5)

- Discovered by mammogram as cluster of microcalcifications and/or density
- Presents less often as a palpable mass or nipple discharge
- Before mammogram screening, DCIS accounted for 1% of all breast cancers

TABLE 7 Breast Cancer Intrinsic Subtypes

Subtype	Characteristics	Markers
Luminal A	Low grade High ER ~40% of all breast cancer Good prognosis	ER+, PR+, *HER2*– Low Ki-67 (<14%)
Luminal B	Higher grade Lower ER ~20% of all breast cancer Poorer prognosis than luminal A	ER+, PR+/–, *HER2*+/– High Ki-67 (>14%)
HER2-enriched	High grade Often node positive *P53* mutations ~10%-15% of all breast cancer	ER–, PR–, *HER2*+
Basal-like	High proliferation *BRCA* dysfunction ~15%-20% of all breast cancer Poor prognosis	ER–, PR–, *HER2*– CK5/6 Or EGFR+

CK, Cytokeratin; *EGFR*, epidermal growth factor receptor; *ER*, estrogen receptor; *HER2*, human epidermal growth factor receptor 2; *PR*, progesterone receptor.
(From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

TABLE 8 Treatment According to Breast Cancer Subtype

Subtype	Treatment Response and Prognosis
Luminal A	Respond to endocrine therapy • Premenopausal: SERMs (tamoxifen) • Postmenopausal: AIs (exemestane, anastrozole, letrozole)
Luminal B	Response to endocrine therapy lower Response to chemotherapy greater than luminal A
HER2-enriched	Respond to anti-*HER2* agents (trastuzumab, pertuzumab, lapatinib)
Basal-like	No response to endocrine therapy or anti-*HER2* agents Chemotherapy only treatment outside of a clinical trial

AIs, Aromatase inhibitors; *HER2*, human epidermal growth factor receptor 2; *SERMs*, selective estrogen receptor modulators.
(From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

TABLE 9 Commonly Used Cytotoxic Chemotherapy and Anti-*HER2* Therapy Drugs in Metastatic Breast Cancer

Cytotoxic Chemotherapy
Albumin-bound paclitaxel
Capecitabine
Cisplatin
Carboplatin
Docetaxel
Doxorubicin
Epirubicin
Eribulin
Gemcitabine
Ixabepilone
Vinorelbine

Anti-*Her2* Therapy
Ado-trastuzumab emtansine
Lapatinib
Pertuzumab
Trastuzumab

(From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

- Now 15% to 20% or even higher proportion have DCIS
- Treated with lumpectomy with cure rates 98% to 99%
- Higher-risk cases require breast radiation and adjuvant hormone therapy
- Mastectomy possibly required with multifocal and/or high-grade DCIS

INFLAMMATORY CARCINOMA

- Rare, rapidly progressive and often lethal form of breast cancer
- Presents as erythematous and edematous breast resembling mastitis
- Biopsy required, including that of the skin
- Treatment with upfront combination chemotherapy followed by surgery and radiotherapy
- Prognosis once dismal; now 5-yr disease-free survival approaches 50% (Fig. E5)

COMMENTS

- The U.S. Preventive Services Task Force (USPSTF) now recommends against automatic "routine" screening of younger women (age range 40 to 49). The task force recommends biennial screening mammography for all middle-aged women (age range 50 to 74). It also states that current evidence is insufficient to assess the benefits and harms of screening mammography in older women (aged 75 and older). The task force also discourages women from performing breast self-examination. Several other U.S. organizations, such as the American Congress of Obstetricians and Gynecologists, however, still recommend annual screening beginning at age 40 yr. Breast cancer screening recommendations by organization are summarized in Table 10.
- The American Cancer Society guidelines for breast cancer screening are summarized in the following:
  1. Women with an *average risk* of breast cancer should undergo regular screening mammography as below:
     a. Women should have the opportunity to begin annual screening between the ages of 40 and 44 yr. (Qualified recommendation)
     b. Women aged 45 to 54 yr should be screened annually. (Qualified recommendation)
     c. Women 55 yr and older should transition to biennial screening or have the opportunity to continue screening annually. (Qualified recommendation)
  2. Women should continue screening mammography as long as their overall health is good and they have a life expectancy of 10 yr or longer. (Qualified recommendation)
  3. Women who are at *high risk* for breast cancer based on certain factors should get an MRI and a mammogram every yr, typically starting at age 30 yr. This includes women who:
     a. Have a lifetime risk of breast cancer of about 20% to 25% or greater, according to risk assessment tools that are based mainly on family history.
     b. Have a known *BRCA1* or *BRCA2* gene mutation (based on genetic testing).
     c. Have a first-degree relative (parent, brother, sister, or child) with a *BRCA1* or *BRCA2* gene mutation and have not had genetic testing themselves.
     d. Had radiation therapy to the chest between the ages of 10 and 30 yr.
     e. Have Li-Fraumeni syndrome, Cowden syndrome, or Bannayan-Riley-Ruvalcaba syndrome, or have first-degree relatives with one of these syndromes.
- Physicians should be familiar with the risks and benefits of various competing recommendations in order to better counsel patients.
- Breast radiologic evaluation, evaluation of nipple discharge, and evaluation of palpable mass are described in Section III.
- Exposure of the heart to ionizing radiation during breast cancer radiotherapy increases risk of ischemic heart disease. The increased rate of ischemic heart disease begins within a few yrs of exposure and continues for at least 20 yr. The increase is proportional to the mean radiation dose to the heart.

RISK REDUCTION STRATEGIES

- Prophylactic bilateral mastectomy reduces the risk for invasive breast cancer by >90%.
- Counseling points for women with average risk interested in contralateral prophylactic mastectomy (CPM) are summarized in Box 3.
- Selective estrogen receptor modulators (SERM) reduce the incidence of hormone receptor-positive invasive breast cancer by 50%.
- Ovarian failure is a common toxic effect of chemotherapy. Administration of the gonadotropin-releasing hormone (GnRH) agonist Goserelin appears to protect against ovarian failure, reducing the risk of early menopause and improving prospects for fertility.

TABLE 10 Breast Cancer Screening Recommendations by Organization

Organization	When to Initiate Screening	Frequency of Screening	When to Stop Screening
American Academy of Family Physicians (AAFP)	Follow U.S. Preventive Services Task Force (USPSTF) recommendations	Follow USPSTF recommendations	Follow USPSTF recommendations
American Cancer Society (ACS)	Opportunity to begin screening at ages 40-44 Regular screening starting at age 45	Annually from age 45-54 Biennially starting at age 55 with opportunity to continue annually	Continue screening mammography as long as overall health is good and life expectancy is 10 yr or longer
American College of Obstetricians and Gynecologists (ACOG)	Annual screening starting at age 40	Annually	Not specified
American College of Physicians (ACP)	Individualized for women ages 40-49 Regular screening starting at age 50	Biennially	Age 75 yr or older Women of any age with life expectancy <10 yr
American College of Radiology (ACR)	Annual screening starting at age 40	Annually	Should be considered as long as the patient is in good health and is willing to undergo additional testing if an abnormality is detected
National Comprehensive Cancer Network (NCCN)	Annual screening starting at age 40	Annually	Upper age limit is not yet established Consider comorbid conditions limiting life expectancy (e.g., ≤10 yr) and whether therapeutic interventions are planned
U.S. Preventive Services Task Force (USPSTF)	Individualized for women ages 40-49 Regular screening beginning at age 50	Biennially	Insufficient evidence to recommend for or against screening at age 75 or older

BOX 3 Counseling Points for Women with Average Risk Interested in Contralateral Prophylactic Mastectomy (CPM)

- There is a low annual contralateral breast cancer risk in women with average risk factors.
- Risk of contralateral breast cancer is decreasing with use of adjuvant therapy.
- Removing the contralateral breast does not decrease the risk for developing distant metastases.
- Breast cancer does not commonly metastasize from one breast to the other.
- CPM does not improve breast cancer–specific survival.
- CPM does not decrease local recurrence.
- Contralateral breast cancers tend to be at a lower stage than the initial primary cancer.
- CPM increases the surgical complication risk.
- Choice of CPM may influence reconstruction options.
- There are alternatives to CPM, including chemoprevention and surveillance.

(From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

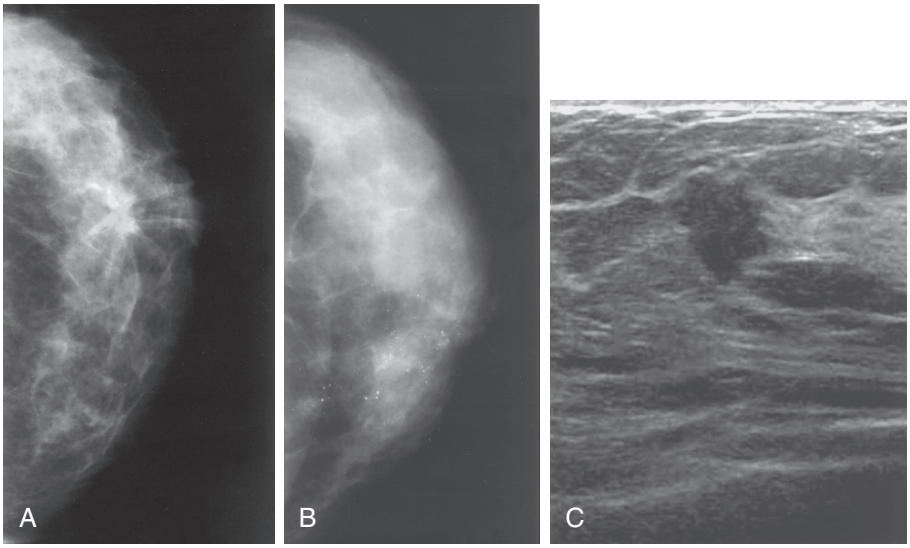

FIG. E2 Mammogram and ultrasound findings of breast disease. A, A stellate mass in the breast. The combination of a density with spiculated borders and distortion of surrounding breast architecture suggests a malignancy. **B,** Clustered microcalcification. Fine, pleomorphic, and linear calcifications that cluster together suggest the diagnosis of ductal carcinoma in situ (DCIS). **C,** An ultrasound image of breast cancer. The mass is solid, containing internal echoes, and displaying an irregular border. Most malignant lesions are taller than they are wide. (From Townsend CM et al [eds]: *Sabiston textbook of surgery*, ed 17, Philadelphia, 2004, WB Saunders.)

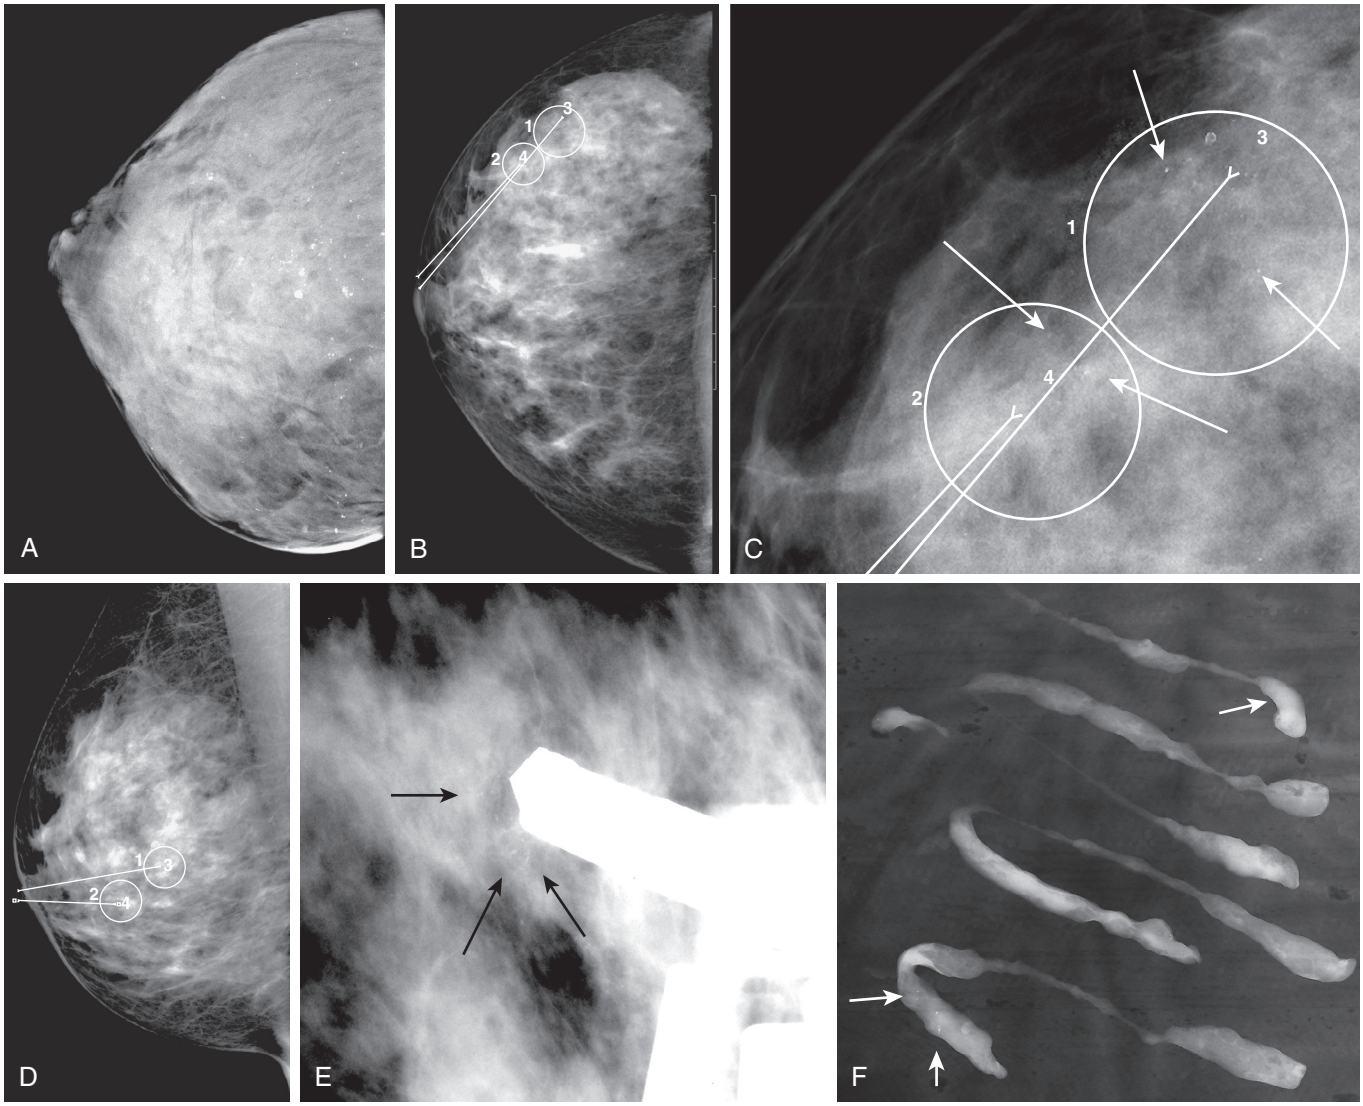

FIG. E3 Digital mammography and workup of breast calcifications. A, Craniocaudal (CC) view in a routine screening of a 43-yr-old woman. Digital mammography penetrates dense breast tissue better than film-screen mammography, clearly showing diffuse benign pattern of large and small calcifications throughout the breast. **B,** CC view in a routine screening of a 46-yr-old woman. Digital mammography shows two areas of very faint calcification in the outer breast that require further workup. **C,** Close-up view of **B,** showing the calcifications (*arrows*) to be variable in size and shape, which is worrisome for malignancy, particularly ductal carcinoma in situ. Such tiny calcifications in a background of dense breast stroma are easier to see on digital mammography than on film-screen mammography. Computer-assisted diagnosis programs also help the radiologist to locate even tiny groups of faint calcifications such as these. **D,** Mediolateral view in the same patient as in **B,** showing that the calcifications are in the lower breast. **E,** Image from stereo core biopsy procedure in the same patient as in **B,** showing the core needle immediately proximal to one of the groups of calcifications. Stereo core biopsy allows histologic sampling of tiny groups of calcifications, which can be very helpful in planning surgical approach. This interventional procedure can decrease the total number of surgeries that a patient must undergo to achieve definitive treatment. **F,** Radiograph of specimen from stereo core biopsy procedure on the same patient as in **B,** showing that there are several tiny calcifications (*arrows*) within some of the core samples. Pathologic analysis of the core biopsy revealed ductal carcinoma in situ, high grade, with comedo features. (From Skarin AT: *Atlas of diagnostic oncology*, ed 4, Philadelphia, 2010, Elsevier.)

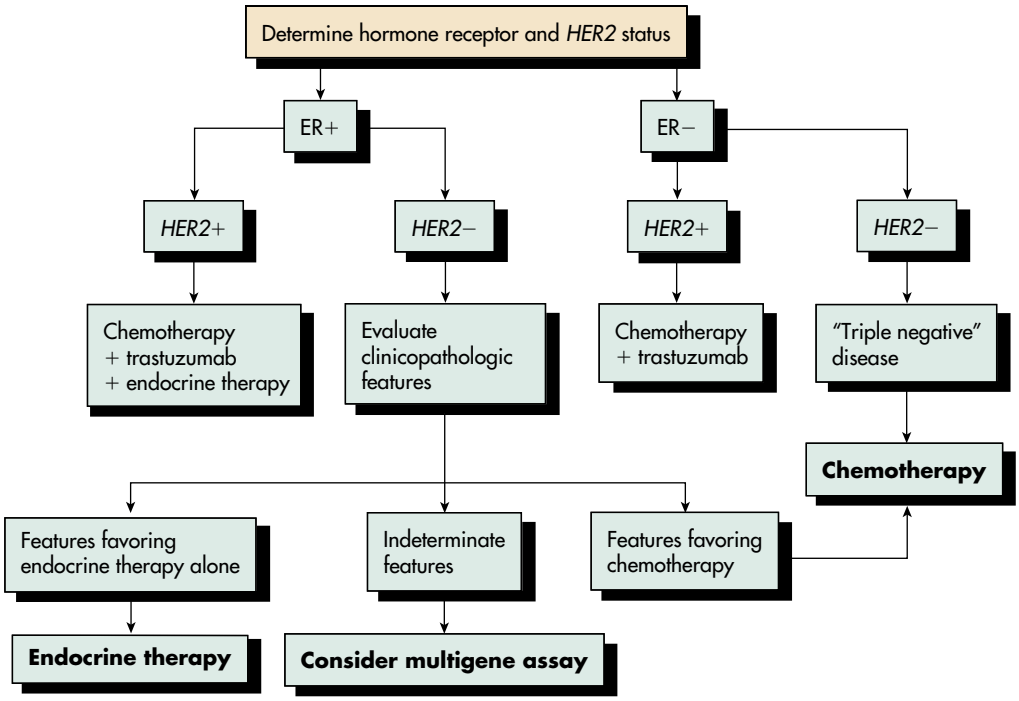

FIG. E4 Management of recurrent and metastatic breast cancer. Considerations for adjuvant chemotherapy. *ER,* Estrogen receptor; *HER2,* human epidermal growth factor receptor 2. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, WB Saunders.)

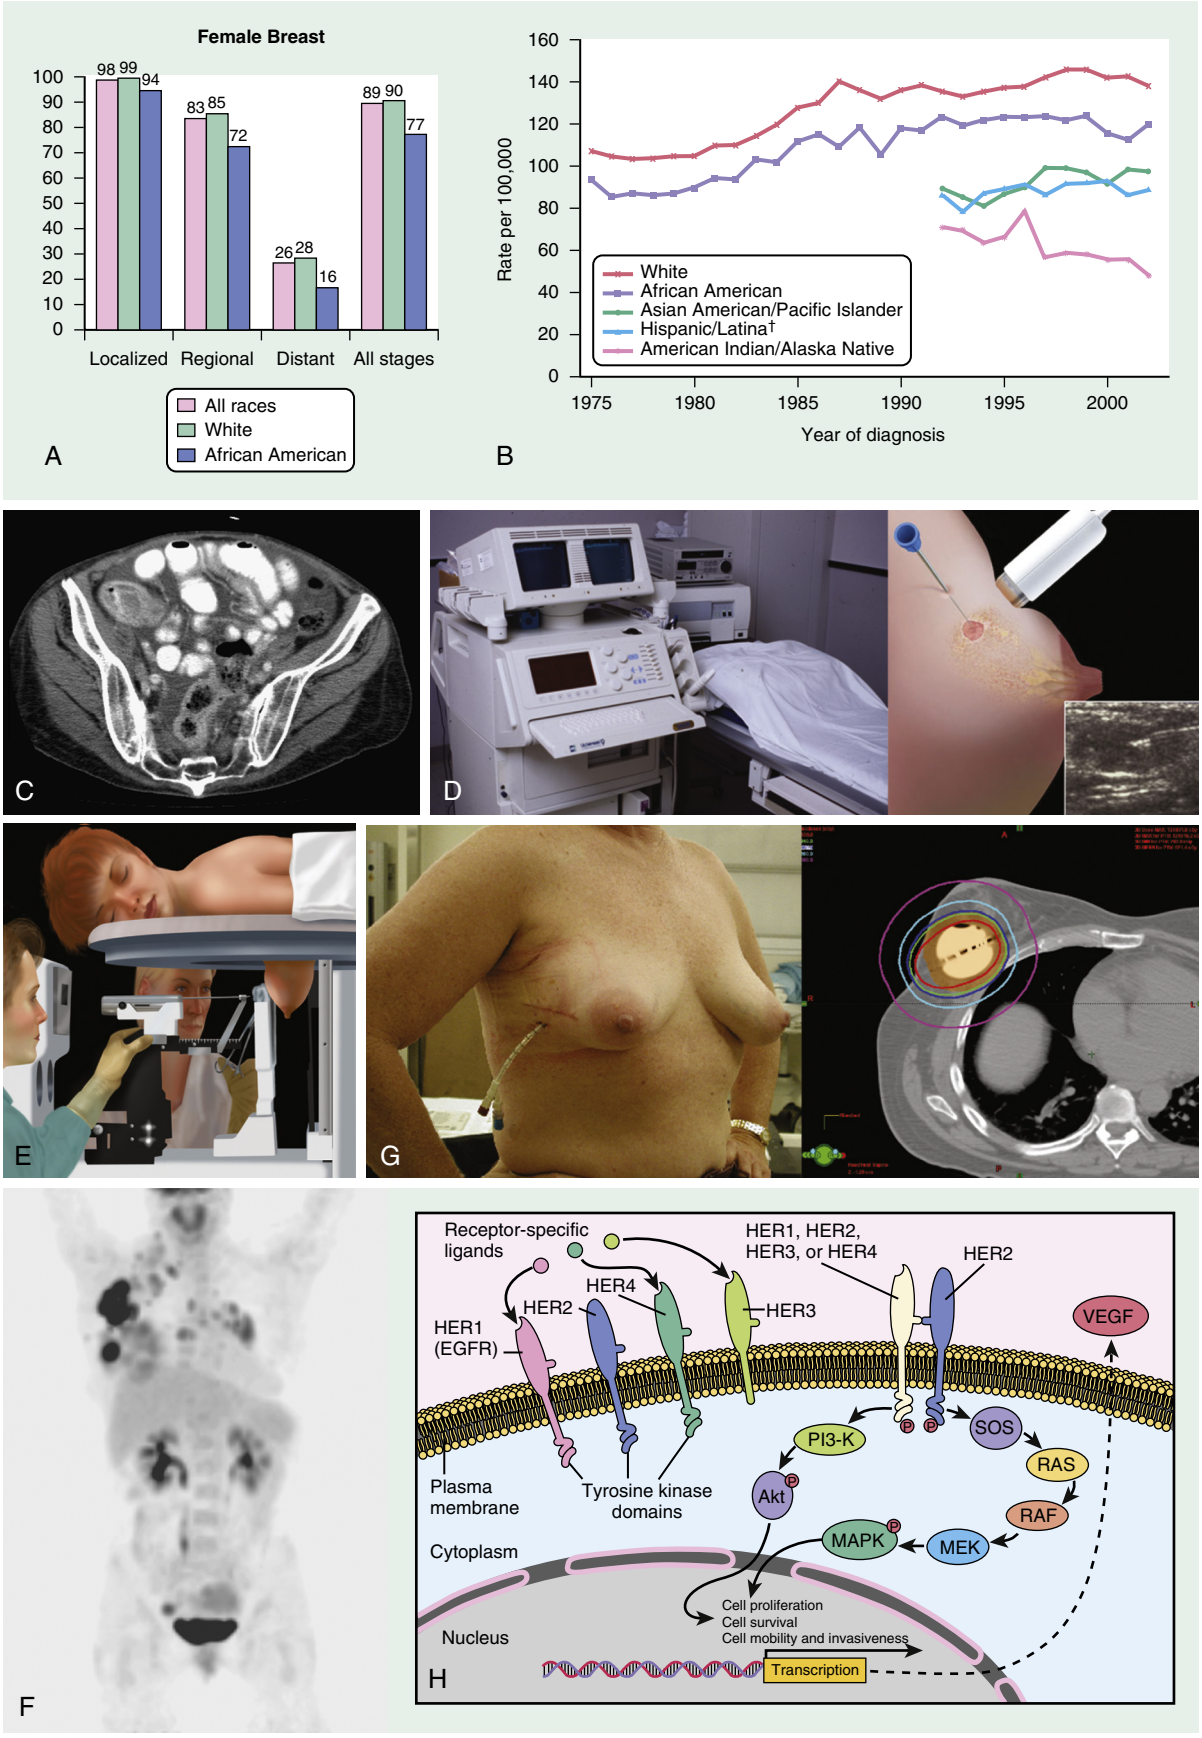

FIG. E5 A, 5-yr relative survival by race and stage at diagnosis of breast cancer (SEER data, 1996-2002). **B,** Female breast cancer incidence by race and ethnicity (SEER data). **C,** When lobular breast cancer metastasizes, it can often infiltrate serosal surfaces, mimicking ovarian cancer. This patient presented with abdominal

Continued

FIG. E5 (Continued)
bloating, tightness, and narrowing in her stool caliber 9 yr after the diagnosis of a stage I breast cancer. Note the diffuse thickening of the rectal and colonic wall, peritoneal carcinomatosis, and ascites. A colonoscopy was performed, and biopsy confirmed diffuse involvement with metastatic adenocarcinoma consistent with a breast primary. On restaging, she was also noted to have multiple osseous metastases. **D,** In an ultrasound-guided needle biopsy, the ultrasound probe is used to localize the lesion that was identified either on physical examination or on mammogram. A biopsy needle is passed through the lesion several times to obtain tissue. Compared to a stereotactic biopsy, an ultrasound-guided biopsy is faster and better tolerated by most patients. However, not all lesions may be amenable to an ultrasound-guided biopsy. **E,** The premise behind stereotactic needle biopsy is that a lesion can be localized in 3D by evaluating its changes in position in a series of angled radiographic views. First, a radiograph localizes the suspicious area; then two additional views, angled 15 degrees to either side of the lesion, are obtained. A computer calculates how much the lesion's position appears to have changed on each of the angled views and uses these data to estimate the lesion's location within 3D space. With the advent of digital mammography, these images are commonly acquired digitally. **F,** Positron emission tomography (PET) involves injection of a substance labeled with a positron-emitting isotope (commonly, fluorine-18 bound to D-glucose, called FDG for 2-([18F]fluoro-2-deoxy-D-glucose)). Metabolically active cells, especially malignant ones, preferentially take up glucose and therefore FDG, as compared with nonneoplastic tissue. Sensitivity of PET can vary considerably by tumor type and size. False-positive results can occur in areas of inflammation or infection. Many machines now acquire CT images in tandem with PET images, which can then be fused together to provide anatomic correlation by CT with metabolic activity measurements by PET. This patient presented with palpable axillary adenopathy and a large breast mass with associated erythema, skin edema, and nipple retraction. Note the extremely intense areas of uptake within the right breast and axilla corresponding to the patient's known locally advanced breast cancer. Also note the intense uptake in the right supraclavicular, paratracheal, prevascular, precarinal, and hilar lymph nodes suspicious for metastatic disease. Uptake in the kidney, bladder, and ureters is physiologic and due to FDG excretion. Uptake in the right adnexa and jaw is most likely physiologic and benign. **G,** Panels 1 and 2: Accelerated partial breast irradiation (APBI) encompasses techniques including intracavitary and interstitial brachytherapy as well as 3D-conformal, intensity-modulated, and intraoperative external-beam radiation therapy. One of the more commonly used brachytherapy methods in the U.S., the MammoSite Brachytherapy System (Hologic, Massachusetts), involves insertion of a catheter with a balloon tip into the lumpectomy cavity at the time of surgery or shortly thereafter (panel 1). The balloon is filled with saline, and a high-dose-rate radioactive source is introduced twice per day for 5 days by computed axial tomography scan–based treatment planning, permitting a highly conformal dose to be delivered to the first centimeter of remaining breast tissue with optimal sparing of the remaining tissue and other regional organs (panel 2). The balloon catheter is removed upon completion. APBI is an option only for selected patients, mainly older women with smaller, node-negative "low-risk" tumors and with negative margins. **H,** The *HER* family of receptors (human epidermal growth factor receptor, also called ErbB) is a group of transmembrane tyrosine kinase receptors that regulate cell growth, survival, and differentiation via a variety of pathways, including RAS (rat sarcoma), RAF (receptor activation factor), MAPK (mitogen-activated protein kinase), and MEK (mitogen extracellular signal kinase). The tyrosine kinase domains are activated by dimerization. Current therapeutics involve tyrosine kinase inhibitors (e.g., lapatinib) and antibodies directed against the *HER2* protein and VEGF (vascular endothelial growth factor) (e.g., trastuzumab and bevacizumab). *Akt,* protein kinase B; *PI3-K,* phosphatidylinositol 3-kinase; *SOS,* Son of sevenless. Devlin, MD, Dana Farber/Brigham and Women's Cancer Center, Harvard Medical School, Boston, MA.)

BASIC INFORMATION

DEFINITION

Breech presentation occurs when fetal longitudinal axis is such that the cephalic pole occupies the uterine fundus (Fig. E1). Three types exist: Frank (48% to 73%, flexed hips, extended knees), complete (4.6% to 11.5%, flexed hips and knees), and footling (12% to 38%, hips extended).

ICD-10CM CODES

O83	Breech extraction
O83.1	Other assisted breech delivery
O83.2	Other manipulation assisted delivery (version with extraction)
O32.	Maternal care for malpresentation
O32.1	Maternal care for breech presentation
O32.8	Maternal care for footling, incomplete, prolapsed breech
P03.0	Newborn affected by breech delivery and extraction

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Gestational age dependent: 3% to 4% overall, 14% at 29 to 32 wk, 33% at 21 to 24 wk

PERINATAL MORTALITY: Three to five times increase over vertex presentation at term, regardless of delivery route. When corrected for associated increase in congenital anomalies and complications of prematurity, morbidity and mortality rates approach those of vertex presentation at term regardless of delivery route.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Lack of presenting part on vaginal examination
- Fetal heart tones heard above the umbilicus
- Leopold maneuvers revealing mobile fetal part in the uterine fundus

ETIOLOGY

- Abnormal placentation (fundal), uterine anomalies (fibroids, septa), pelvic or adnexal masses, alterations in fetal muscular tone, or fetal malformations
- Associated conditions: Trisomy 13, 18, 21; Potter syndrome; myotonic dystrophy; prematurity

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Vertex, oblique, or transverse lie

WORKUP

- Determine if any etiology for breech presentation exists that may affect mode of delivery selection: Presence of uterine anomalies (fibroids, septum, Mullerian anomaly), placentation issues, estimated gestational age of fetus, fetal congenital anomalies, fetal aneuploidy.
- If fetus viable and it is clinically indicated, assess fetal status by continuous FHR monitoring.
- Perform ultrasound to confirm position and presenting part (see "Imaging Studies").
- Assess pelvis to determine feasibility of vaginal delivery.
- Assess other comorbidities in regards to safety of vaginal versus abdominal delivery.

IMAGING STUDIES

Ultrasound to evaluate for:

- Fetal anomalies
- Placental location
- Position of fetal head relative to spine (check for hyperextension)
- Estimated fetal weight (2500-3800 g for attempt of vaginal delivery)
- Type of breech (frank, complete, footling)
- Gestational age

TREATMENT

ACUTE GENERAL Rx

- Vaginal delivery in breech position.
  1. Vaginal delivery in selected patients (see "Comments" section): Allow maternal expulsive forces to deliver fetus until scapula visible (avoiding traction); with flexion and/or Piper forceps, deliver fetal head
- Cesarean delivery.
  1. Perform cesarean section (see "Comments").
- External cephalic version followed by induction of labor and attempt at vaginal delivery in vertex position.
  1. Improved success if >37 wk. Success rates range from 16% to 100%. Adequate uterine relaxation is essential. Use of terbutaline and/or epidural anesthesia improves success rates. Data are not adequate to establish absolute or relative contraindications; must individualize. Contraindicated if vaginal delivery is not appropriate. In general, contraindicated with active placental abruption, placenta previa, certain fetal anomalies, version of a first breech presenting multiple gestation, or nonreassuring fetal status. Other relative contraindications: Perform with caution with low-lying placenta, prior uterine incision, and preterm gestation. Informed consent includes risks of abruption, cord prolapse, rupture of membranes, stillbirth, and hemorrhage (<1%).

COMPLICATIONS

- Head entrapment: Leading cause of death (with the exception of anomalous fetuses); 88 cases per 1000 deliveries; avoid by maintaining flexion of fetal head (Mauriceau Smellie Veit maneuver), use of Piper forceps or Dührssen incisions. Avoid hyperextension of head during delivery.
- Cord prolapse: Usually occurs late in labor. Incidence depends on type of breech: Frank (0.5%), complete (4%-5%), footling (10%).
- Nuchal arm: Arm extended above fetal head; occurs when there is undue traction before delivery of fetal scapulas. Treatment: Bring trapped arm across infant's face (Lovset maneuver).

DISPOSITION

If confounding variables are corrected for (prematurity, associated congenital anomalies [6.3% of breeches vs. 2.4% in general population]), route of delivery plays less important role in fetal outcome than previously believed if the obstetrician performing the delivery is experienced in breech delivery. Since the publication of the Term Breech Trial in 2000, planned cesarean is becoming the preferred mode of birth for women with a breech fetus. In addition,

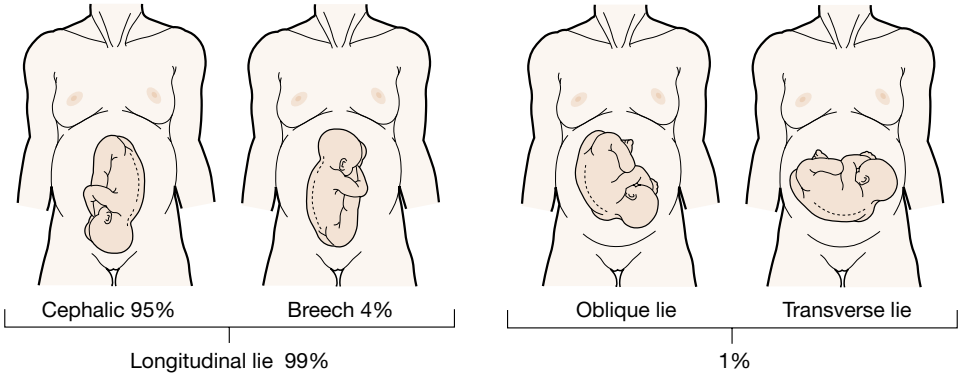

FIG. E1 Fetal lie at term. (From Magown BA: *Clinical obstetrics & gynaecology,* ed 4, 2019, Elsevier.)

as seasoned obstetricians retire, and fewer new physicians are taught the technique of breech delivery, despite relative safety, this modality as an option for delivery has decreased over time.

REFERRAL

An obstetrician trained in vaginal breech delivery is prerequisite for attempt; explain to the patient that with cesarean section, certain risks (i.e., hyperextension of the fetal head with resultant spinal cord injury) may be minimized but not eliminated. Cesarean section also comes with its own risks and requires informed consent as well.

PEARLS & CONSIDERATIONS

COMMENTS

Since the publication of the Term Breech Trial in 2000, little evidence has proven conclusively that cesarean birth is safer than vaginal birth of a fetus in a breech presentation when certain criteria are met. For a planned vaginal delivery of the breech presentation, mortality rate increased thirteenfold and morbidity sevenfold, mainly because of an increase in congenital anomalies, perinatal hypoxia, birth injury, and prematurity. Based on the 2015 Cochrane Review, planned cesarean section compared with planned vaginal birth reduced perinatal or neonatal death as well as the composite outcome death or serious neonatal morbidity, at the expense of increased maternal morbidity. In a subset with 2-yr follow-up, infant medical problems were increased following planned c-section, and no difference in long-term neurodevelopmental delay was found. There is no contraindication to induction of labor in breech presentation or planned breech delivery in primigravidas. Many obstetric organizations support the option of a planned vaginal birth for women with a breech presentation. The benefits need to be weighed against factors such as mother's preference for vaginal birth and risks such as future pregnancy complications. Planned vaginal delivery of term singleton breech fetus is reasonable under a hospital-specific strict prelabor selection criteria with intrapartum management guidelines/protocols, and with an experienced provider and informed consent of the patient.

CRITERIA FOR TRIAL OF LABOR WITH A PLANNED BREECH DELIVERY

- Gestational age >37 wk (proceed with caution in preterm delivery of the breech fetus; consider Maternal-Fetal Medicine consultation in these situations)
- Estimated fetal weight, 2500 to 4000 g—recognizing inherent error in estimated fetal weight approximations; actual fetal weight may be substantially smaller or larger (proceed with caution in fetuses weighing 1500-2500 g; consider Maternal-Fetal Medicine consultation in these situations)
- Adequate pelvis
- Flexed fetal head
- Frank or complete breech preferred if planning induction, although in active spontaneous unplanned labor, footling breech can be delivered safely if no cord prolapse
- No known fetal anomalies
- Normal amniotic fluid index (consider at minimum presence of mean vertical pocket >2 cm)
- Bedside availability of anesthesia and capability for immediate cesarean section (consider epidural placement; consider delivery in operating room in the event of need for emergent cesarean section)
- Informed consent
- Obstetrician trained in vaginal breech delivery

SUGGESTIONS FOR WHEN TO CONSIDER A PLANNED CESAREAN SECTION FOR BREECH

- Estimated fetal weight <1500 g or >4000 g
- Footling presentation (20% risk of cord prolapse, usually late in course of labor)
- Inadequate pelvis
- Hyperextended fetal head (21% risk of spinal cord injury)
- Nonreassuring fetal status
- Abnormal progress of labor
- Lack of trained obstetrician

BASIC INFORMATION

DEFINITION

Bronchiectasis is an irreversible pathologic dilatation of the bronchi or bronchioles resulting from a variety of causes through an interplay of host factors (either anatomic or immune defense abnormality), respiratory pathogens, and environmental factors. Radiographically, it is often divided into cylindrical, varicose, and cystic varieties, although these variants have no significant etiologic or prognostic relevance.

ICD-10CM CODES

J47.0	Bronchiectasis with acute lower respiratory infection
J47.1	Bronchiectasis with (acute) exacerbation
J47.9	Bronchiectasis, uncomplicated
Q33.4	Congenital bronchiectasis

EPIDEMIOLOGY & DEMOGRAPHICS

- The exact prevalence of bronchiectasis is unknown.
- Cystic fibrosis is responsible for nearly 50% of all cases of bronchiectasis.
- Acquired primary bronchiectasis is uncommon because of rapid diagnosis of pulmonary infections and frequent use of antibiotics.
- Effective childhood immunizations have led to a significant decrease in the incidence of bronchiectasis resulting from pertussis.
- Declining incidence of pulmonary tuberculosis has also resulted in a decline in bronchiectasis without apparent causes.
- In developed countries, an increasing proportion of patients with an identifiable cause of bronchiectasis is being seen.
- Data on morbidity and mortality from bronchiectasis are limited because patients with the highest morbidity typically are not adequately represented in randomized controlled studies.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Moist crackles at lung bases
- Chronic cough, typically with expectoration of large amount of purulent sputum
- Fever, night sweats, generalized malaise, weight loss
- Hemoptysis
- Halitosis, skin pallor
- Clubbing (infrequent)

ETIOLOGY

- Cystic fibrosis
- Lung infections (pneumonia, lung abscess, TB, nontubercular mycobacterial infections, fungal infections, viral infections)
- Impaired host defense (panhypogammaglobulinemia, primary ciliary dyskinesia/Kartagener syndrome, AIDS, chemotherapy)
- Localized airway obstruction (congenital structural defects, foreign bodies, neoplasms)
- Inflammation (inflammatory pneumonitis, granulomatous lung disease, allergic aspergillosis)
- Rheumatoid arthritis, ulcerative colitis, and so on
- Congenital disorders such as tracheobronchomegaly (Mounier Kuhn syndrome), cartilage deficiency (Williams-Campbell syndrome)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- TB
- Asthma
- Chronic bronchitis or chronic rhinosinusitis
- Interstitial fibrosis
- Chronic lung abscess
- Foreign body aspiration
- Cystic fibrosis
- Lung carcinoma
- GERD

LABORATORY TESTS

- Sputum for Gram stain, culture and sensitivity, and acid-fast bacteria
- Complete blood count with differential (leukocytosis with left shift, anemia)
- Serum protein electrophoresis to evaluate for hypogammaglobulinemia
- Antibody test for aspergillosis
- Testing for allergic bronchopulmonary aspergillosis
- Serum immunoglobulins (total IgG, IgA, IgM)
- Sweat test in patients with suspected cystic fibrosis
- Pulmonary function tests: Mild to moderate airflow obstruction
- Serum anti-*Pseudomonas aeruginosa* (PA) IgG antibody testing is highly accurate to detect chronic PA colonization in bronchiectasis patients

IMAGING STUDIES

- Chest x-ray (Fig. E1 and Fig. E2): Hyperinflation, crowded lung markings, small cystic spaces at the base of the lungs.
- High-resolution CT scan of the chest (Figs. E3 to E6) has become the best tool to detect cystic lesions and exclude underlying obstruction from neoplasm with a sensitivity and specificity exceeding 90%. The CT study should be a noncontrast study with the use of 1- to 1.5-mm window every 1 cm with acquisition time of 1 sec. Typical findings on CT include enlarged internal bronchial diameter, bronchi appearing larger than accompanying artery, lack of tapering of an airway toward periphery, ballooned cysts at the end of bronchus, and varicose constrictions along airways.
- Bronchoscopy may be helpful to evaluate hemoptysis, rule out obstructive lesions, remove mucus plugs, and also obtain microbiologic data on respiratory pathogens.
- Table 1 summarizes diagnostic studies for the classification and management of patients with bronchiectasis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Postural drainage (reclining prone on a bed with the head down on the side) and chest percussion with use of inflatable vests/high-frequency chest wall oscillation or mechanical vibrators applied to the chest may enhance removal of respiratory secretions.
- Adequate hydration.
- Supplemental oxygen for hypoxemia.
- Inhaled hypertonic saline in conjunction with chest physiotherapy improves airway clearance.

ACUTE GENERAL Rx

- Antibiotic therapy is based on the results of sputum, Gram stain, and culture and sensitivity; in patients with inadequate or inconclusive results, empiric therapy with amoxicillin/clavulanate 500 to 875 mg q12h, TMP-SMX q12h, doxycycline 100 mg bid, a fluoroquinolone, or cefuroxime 250 mg bid for 14 to 21 days is recommended.
- There is strong consideration for intravenous antibiotics in patients who require hospitalizations for acute exacerbation with signs of respiratory distress.
- Bronchodilators are useful in patients with demonstrable airflow obstruction.

CHRONIC Rx

- Avoidance of tobacco.
- Maintenance of proper nutrition and hydration.
- Prompt identification and treatment of infections.
- Pneumococcal vaccination and annual influenza vaccination.
- In patients with cystic fibrosis, using rhDNase and aerosolized antipseudomonal antibiotics should be considered. This should not be offered to patients with non–cystic fibrosis related bronchiectasis.
- Specific immunoglobulin replacement in patients with selective immunoglobulin deficiency.
- Adults with bronchiectasis with a new isolation of *P. aeruginosa* should be offered eradication antibiotic treatment. This should not be offered to adults with bronchiectasis following new isolation of pathogens other than *P. aeruginosa.*
- Inhaled corticosteroids should not be offered to adults with isolated bronchiectasis. However, the diagnosis of bronchiectasis should not affect the use of inhaled corticosteroid in patients with comorbid asthma of chronic obstructive pulmonary disease.
- Long-term antibiotics should be offered for adults with bronchiectasis who have three or more exacerbations per yr.
- Long-term mucoactive treatment (≥3 mo) should be considered in patients who have difficulty in expectorating sputum and poor quality of life and where standard airway clearance techniques such as chest physiotherapy have failed to control symptoms.
- Bronchodilators should be used before physiotherapy, including inhaled mucoactive drugs, as well as before inhaled antibiotics, as this increases tolerability and optimizes delivery of medications in diseased areas of the lungs.

TABLE 1 Diagnostic Studies for the Classification and Management of Patients with Bronchiectasis

Test	Comments
Routine, Universal Studies	
Computed tomography lung scan (CTLS)	If bronchiectasis (BXSIS) is suspected, CTLS is the definitive test. Thin-section, high-resolution images may help detect subtle airway dilation before bronchial walls are grossly thickened. Contrast is generally not helpful and may, in fact, compromise the overall resolution of the study. CTLS may also identify esophageal abnormalities.
Pulmonary function tests (PFTs)	For patients with significant bronchiectasis, comprehensive PFTs, including spirometry, bronchodilator responsiveness, lung volumes, and diffusion capacity, are important studies that aid in management and prognosis. PFTs may also provide useful hints regarding predisposing conditions.
Complete blood count	Anemia may reflect effects of chronic infection or blood loss (consider inflammatory bowel disorders). Leukocytosis may mark severity of infection. Eosinophilia may suggest ABPA/M.
ESR, C-reactive protein	Nonspecific markers of inflammation; very high levels may suggest underlying connective tissue disease or vasculitis.
Routine sputum culture	Antibiotic therapy in bronchiectasis should generally be directed against specific pathogens and guided by in vitro susceptibility. The presence of mucoid strains of *Pseudomonas aeruginosa* and *Staphylococcus aureus* may raise suspicions for CF. *Stenotrophomonas maltophilia*, *Alcaligenes xylosoxidans*, and *Burkholderia cepacia* are gram-negative bacilli that may prove problematic pathogens in patients with long-standing bronchiectasis. Isolation of *B. cepacia* and *Helicobacter pylori* requires special laboratory techniques.
Mycobacterial sputum culture	Environmental mycobacteria such as *Mycobacterium avium* complex, *M. chelonae*, and *M. abscessus* appear to be increasingly common in contemporary bronchiectasis. May be commensal but often are pathogenic.
Fungal sputum culture	In patients with an asthmatic component, the presence of *Aspergillus* species (or other molds including Pseudallescheria or penicillium) may be suggestive of etiology.
CT scan of sinuses	Many patients with bronchiectasis also suffer chronic rhinosinusitis. The presence of extensive sinus involvement suggests possible CF, immunoglobulin deficiencies, or ciliary disorders. Also, optimal management often entails aggressive sinus care.
Specific, Directed Studies	
Sweat chloride, CF genotyping, and nasal potential differences	For bronchiectasis patients with bilateral disease, recurrent sinusitis, and no other identified risk factor, mild variants of CF appear to be relatively common. Sweat chloride is regarded as the primary screening test for CF, but a considerable portion of adults with CF have borderline or normal results. Nasal potential difference may be useful for identifying CF in equivocal cases.
$Alpha_1$-antitrypsin (AAT) levels and phenotype	AAT anomalies appear to be a substantial risk factor for bronchiectasis, especially with white females. Abnormal proteinase inhibitor (Pi) phenotypes, even heterozygous patterns such as MS, appear to confer risk even with normal levels of AAT. Repletion of AAT may enhance resistance to lower respiratory tract infections.
Immunoglobulin (Ig) levels	Deficiencies of IgG or IgA may promote bronchiectasis; IgG subclass deficiencies may also be a factor. Elevated levels of IgE may suggest ABPA/M or Job syndrome. Hyper-IgM may be associated, as well, with chronic infections.
Ciliary morphology or function	For individuals with suggestive stories, a nasal ciliated epithelium biopsy with transmission electron microscopy may identify primary ciliary dyskinesia. Other studies including ex vivo ciliary activity, the saccharine test, or spermatozoa analysis may aid in this diagnosis.
Nasal nitric oxide (NNO) levels	Patients with documented PCD have significantly lower levels of NNO than normal or patients with CF. Although not universally available, such testing may prove highly useful in identifying PCD. Paradoxically, exhaled NO levels have been elevated in bronchiectasis of diverse etiologies except CF.
Barium swallow (BaS)	The BaS may detect disturbed deglutition, esophageal diverticula, obstructing lesions (tumors or strictures), hypomotility, achalasia, hiatal hernias, or lower esophageal sphincter (LES) incompetence with reflux. The absence of reflux on a BaS, however, does not exclude this problem (see pH probe).
pH probe	For patients suspected of gastroesophageal reflux, an 18- to 24-hour study with a transnasal pH probe may identify, quantitate, and characterize reflux. Medications that inhibit acid production must be stopped before such tests.
Esophageal manometry	For patients being considered for surgical repair of the LES, manometry should be performed to determine that the esophagus generates sufficient pressure to propel food and liquids through the tightened sphincter.
Tailored hypopharyngography (TH)	TH is useful in detecting abnormalities of the initial phase of swallowing, deglutition. Persons particularly prone to problems include those with prior strokes, Parkinson disease, bulbar disorders including postpolio syndrome, and those with prior laryngeal or pharyngeal surgery. Note that some patients have gross aspiration without clinical manifestations (choking, coughing); this may occur in individuals with none of the above risk factors.
Less Common, Exotic Studies	
Collagen vascular disease (CVD) serologies	Various CVDs may contribute to the risk for bronchiectasis, including RA, ankylosing spondylitis, and systemic lupus erythematosus. Thus, for patients with compatible histories or physical findings, assays for rheumatoid factor, HLA-B27, and ANA may provide insight into predisposing conditions. CVD serologies may also suggest the diagnosis of Sjögren syndrome, particularly SSA/Ro and/or SSB/La.
Schirmer test	For patients with histories suggestive of "sicca syndrome" (dry eyes, dry mouth, oral ulcers), a positive Schirmer test may indicate the presence of either primary or secondary (associated with a CVD) Sjögren syndrome.

ABPA/M, Allergic bronchopulmonary aspergillosis/other mycoses; *ANA*, antinuclear antibody; *CF*, cystic fibrosis; *ESR*, erythrocyte sedimentation rate; *HLA*, human leukocyte antigen; *MS,* multiple sclerosis; *NO,* nitric oxide; *PCD*, primary ciliary dyskinesia; *RA*, rheumatoid arthritis.
From Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, Saunders.

DISPOSITION

- Prognosis is variable with severity of the disease and underlying etiology of bronchiectasis.
- In overlap syndrome of bronchiectasis with rheumatoid arthritis, worse outcomes occurred compared with other bronchiectasis etiologies.

REFERRAL

- Surgical referral for partial lung resection in patients with localized, severe disease unresponsive to medical therapy or in patients with massive hemoptysis. Surgical resection of localized bronchiectasis is safe and improves quality of life.
- Lung transplantation for bronchiectasis accounts for about 2% to 3% of all lung transplant candidates (*The Registry of the International Society for Heart and Lung Transplantation*).

BASIC INFORMATION

DEFINITION

Brucellosis is a zoonotic infection caused by one of four species of *Brucella*. It commonly presents as a nondescript febrile illness. It is the most common zoonosis worldwide.

SYNONYMS

Malta fever, undulant fever
Bang disease

ICD-10CM CODE
A23.9 Brucellosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): About 100 to 200 cases/yr (may be underreported) (Fig. E1), predominantly *B. melitensis*. The number of cases is increasing worldwide due to travel and globalization.
PREDOMINANT SEX: Male
PREDOMINANT AGE: Adult
CONGENITAL INFECTION: Recent evidence suggests a high rate of spontaneous abortions in untreated pregnant women during the first and second trimesters.
NEONATAL INFECTION: Can occur if mother is infected during pregnancy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation period is 1 wk to 3 mo.
- Patients may be asymptomatic or have nonspecific symptoms such as fever, sweats, malaise, weight loss, depression, arthralgia, and arthritis.
- Fever is the most common finding (Fig. E2).
- Hepatomegaly, splenomegaly, or lymphadenopathy is possible.
- Localized disease includes endocarditis, meningitis, spondylitis, sacroiliitis, and osteomyelitis (especially vertebral).
- Chronic hepatosplenic suppurative brucellosis (CHSB) presents with hepatic or splenic abscesses. This form is thought to be a reactivation and can occur years after the acute infection.
- Table E1 describes a clinical classification of human brucellosis.

ETIOLOGY

- Caused by infection with *Brucella* species:
  1. Most commonly *B. melitensis* but also *B. suis, B. abortus*, or *B. canis*.
  2. A small, gram-negative coccobacillus.
- Acquired through ingestion of organisms (unpasteurized goat's or cow's milk, cheese, or ice cream) or breaks in the skin or by inhalation.
- Most cases occur after exposure to animals (sheep, goats, swine, cattle, or dogs) or animal products (i.e., milk, cheese, hides, tissue).
- Most cases (in the U.S.) occur in men with occupational exposure to animals (e.g., farmers, ranchers, laboratory workers, veterinarians, abattoir workers). Accidental animal vaccine exposure warrants evaluation for a full therapeutic antibiotic regimen.
- Laboratory workers, especially those in microbiology, are also at increased risk. Guidelines for postexposure prophylaxis are available from *MMWR Surveill Summ* 57:39, 2009.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Many febrile conditions without localizing manifestations (i.e., tuberculosis, endocarditis, typhoid fever, malaria, autoimmune diseases)

WORKUP

- Cultures of blood, bone marrow, or other tissue (e.g., lymph node, liver) should be sent and held for 4 wk because *Brucella* spp. grow slowly in vitro.
- Granulomas on biopsy are suggestive of diagnosis.
- Serum agglutination test (see the following).

LABORATORY TESTS

- WBC count: Normal or low.
- Serology:
  1. Serum agglutination test (SAT) to detect antibodies to *B. abortus, B. melitensis,* and *B. suis.* An elevated initial titer of ≥1:160 or demonstration of a fourfold increase from acute to convalescent titers is considered diagnostic. Positive test results warrant confirmatory testing with specific *Brucella* agglutination tests.
  2. Specific antibody test to identify antibodies to *B. canis.*
  3. False-negative SAT possibly resulting from a prozone effect.
  4. PCR (polymerase chain reaction) for *Brucella* spp. specific 16S rRNA or DNA sequences are increasingly used for the

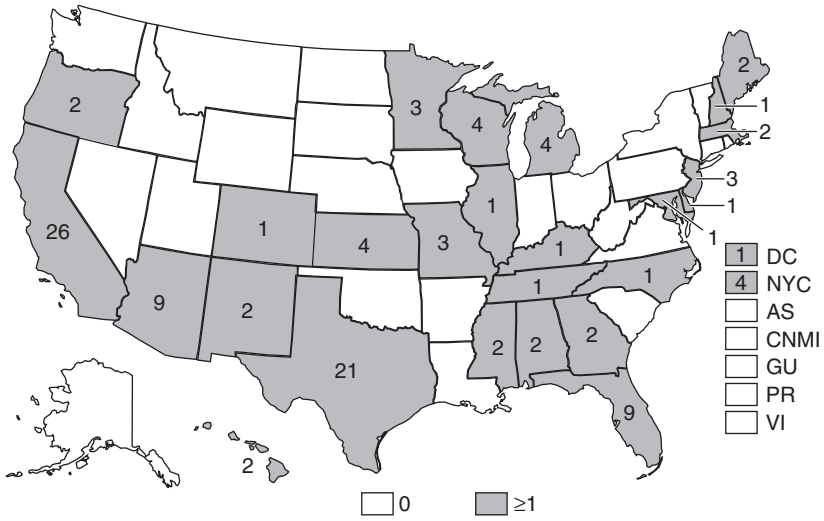

FIG. E1 Brucellosis. Number of reported cases—United States and U.S. territories, 2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR Morb Mortal Wkly Rep* 59:1-111, 2012.)

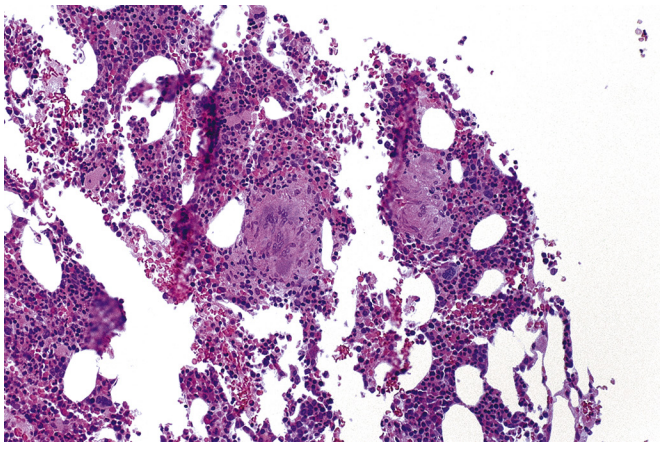

FIG. E2 Brucellosis. Several small noncaseating granulomas are present in the bone marrow of a patient with an unexplained febrile disease. He was not aware of exposure to *Brucella* in over 30 yr (HANDE, ×40, *Brucella suis* isolated from blood cultures). (From Scott MA et al: Infectious disease pathology. Silverberg SG [ed]: *Principles and practice of surgical pathology and cytopathology,* ed 4, Philadelphia, 2006, Churchill Livingstone, p 101.)

TABLE E1 Clinical Classification of Human Brucellosis

Classification	Duration of Symptoms Before Diagnosis	Major Symptoms and Signs	Diagnosis	Comments
Subclinical	—	Asymptomatic	Positive (low titer) serology, negative cultures	Occurs in abattoir workers, farmers, and veterinarians
Acute and subacute	Up to 2-3 mo and 3 mo to 1 yr	Malaise, chills, sweats, fatigue, headache, anorexia, arthralgias, fever, splenomegaly, lymphadenopathy, hepatomegaly	Positive serology, positive blood or bone marrow cultures	Presentation can be mild, self-limited *(B. abortus)* or fulminant with severe complications *(B. melitensis)*
Localized	Occurs with acute or chronic untreated disease	Related to involved organs	Positive serology, positive cultures in specific tissues	Bone or joint, genitourinary, hepatosplenic involvement most common
Relapsing	2-3 mo after initial episode	Same as acute illness but may have higher fever and more fatigue, weakness, chills, and sweats	Positive serology, positive cultures	May be extremely difficult to distinguish relapse from reinfection
Chronic	>1 yr	Nonspecific presentation but neuropsychiatric symptoms and low-grade fever most common	Low titer or negative serology, negative cultures	Most controversial classification; localized disease may be associated

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

diagnosis of brucellosis from blood, tissue samples, and bone marrow.

IMAGING STUDIES

- Radiographs to show splenic or hepatic calcifications in chronic disease
- Bone scan, MRI, and radiographs of the spine to suggest osteomyelitis
- Ultrasound or CT scan of the abdomen to show an enlarged liver or spleen
- Echocardiogram to reveal vegetations in endocarditis

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Drainage of abscesses
- Valve replacement for endocarditis

ACUTE GENERAL Rx

Combination antibiotics required:

- Major options:
  1. Doxycycline 100 mg PO bid for 6 wk plus rifampin plus gentamycin 5 mg/kg qd for 7 days.
- Alternative therapies:
  1. Doxycycline 100 mg PO bid plus rifampin 600 to 900 mg PO qd for 6 wk plus streptomycin.
  2. Sulfamethoxazole 800 mg/trimethoprim 160 mg one DS tablet PO qid, ciprofloxacin 500 mg bid for 6 wk along with doxycycline or rifampin as an alternative regimen.
  3. Courses <6 wk are associated with higher relapse rates; longer courses are recommended for complicated disease (e.g., osteomyelitis, endocarditis, and neurobrucellosis).

DISPOSITION

- Relapse is possible weeks to months after the completion of therapy.
- Reactivation with CHSB has been reported up to 35 yr after initial illness.

REFERRAL

For all cases to an infectious disease specialist

PEARLS & CONSIDERATIONS

COMMENTS

- Alert the microbiology laboratory to the possibility of *Brucella* spp. (prolonged incubation needed and biohazard for laboratory personnel).
- Do not use doxycycline in children or pregnant women.
- Avoid aminoglycosides in pregnant women.
- Fluoroquinolones have good in vitro activity against *Brucella* spp. and are under study as components of complex regimens. However, they do not perform well in the requisite acidic environment.
- Monotherapy is not effective.

BASIC INFORMATION

DEFINITION

Brugada syndrome (BRS) is an inherited disorder involving cardiac sodium channels characterized by typical electrocardiographic abnormalities. Patients with a Brugada pattern on ECG and symptoms such as palpitations, syncope, or sudden death are deemed to have BRS. BRS predisposes one to sudden cardiac death (SCD) secondary to polymorphic ventricular tachycardia (PVT) or ventricular fibrillation (VF) in the absence of structural heart disease.

SYNONYMS

BRS
Sudden unexpected nocturnal death syndrome (SUNDS)

ICD-10CM CODES
I49.9 Cardiac arrhythmia, unspecified
I47.2 Ventricular tachycardia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence ranges from 1 to 5:10,000 people in Europe and 12:10,000 in Southeast Asia.
PREVALENCE: It comprises 4% of SCD and 20% of SCD in structurally normal hearts. Although found in every population, the prevalence is much higher in Asian and Southeast Asian countries; in some Southeast Asian countries, such as Laos and Thailand, it may be the most common form of natural death in younger males.
PREDOMINANT SEX AND AGE: BRS is more common in males (58% to 80% of patients). Mean age at presentation is 40 to 45.
GENETICS: The disease is autosomal dominant with variable expression (Table 1).

- *SCN5A,* the gene that encodes for the alpha subunit of the cardiac sodium channel, accounts for about 20% to 30% of cases of BRS.
- *SCN10a,* the gene that encodes the Nav1.8 subunit of the sodium channel, has been found in 17% of BRS patients, making it the second most-common-known mutation.
- Known genetic abnormalities are only found in half of patients; thus the impact of genetic testing is limited. When available, it may be useful in identifying silent carriers.
- In all genotypes, the basic abnormality is either a decrease in the inward sodium or calcium current or an increase in the outward potassium current.

RISK FACTORS: First-degree relatives with sudden death or known BRS

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical exam is usually benign
- Classic ECG finding is a pattern of atypical right bundle branch block (RBBB) with persistent ST elevation of cove-like morphology and T-wave inversion in the anterior leads (V1 to V2)
- Often an incidental finding diagnosed from a typical ECG pattern
- Palpitations
- Nocturnal agonal respirations
- Syncope
- Sudden cardiac arrest (SCA)/SCD secondary to rapid PVT that frequently degenerates into VF more often at night
- Fig. 1 illustrates Brugada ECG patterns. Type 1 is the most common and characteristic (Fig. 2)
- Type 1 ECG pattern is defined as an elevated ST segment ≥2 mm that descends in a coved pattern to an inverted T wave. This finding can be transient and may be provoked (sodium channel blockers, vagal maneuvers, increased alpha-adrenergic tone, beta-blockers, tricyclic or tetracyclic antidepressants, fever, hypokalemia, hyperkalemia, hypercalcemia, and alcohol and cocaine toxicity)
- Type 2 ECG pattern (Fig. 3) is not diagnostic of BRS but may be suggestive and warrant further testing. This pattern is a "saddle back" ST-T wave morphology with an upright or biphasic T wave. Type 2 (formerly known as types 2 and 3) can change to a type 1 pattern with the triggers noted above. Table 2 describes drugs used to unmask Brugada ECG pattern

ETIOLOGY

Autosomal dominant inheritance with variable penetration

DIAGNOSIS

Diagnosis is made by the presence of a type 1 ECG *and* symptoms.

- ST segment elevation with type 1 morphology ≥2 mm in one or more right-sided leads (V_1 to V_2), occurring either spontaneously or after provocative drug testing
- Type 2 ECG that converts into type 1 following sodium channel blocker (procainamide/flecainide/ajmaline) challenge (Fig. 2)

TABLE 1 Molecular Basis of the Brugada Syndrome

Disease	Gene	Protein	Ionic Current	Function	Inheritance
BRS type 1	*SCN5A*	$Na_v1.5$	Subunit alpha I_{Na}	Loss	Autosomal dominant
BRS type 2	*GPD1L*	G3PD1L	Interaction subunit alpha I_{Na}	Loss	Autosomal dominant
BRS type 3	*CACNA1C*	$Ca_v1.2$	Subunit alpha I_{CaL}	Loss	Autosomal dominant
BRS type 4	*CACNB2B*	$Ca_v\beta_2$	Subunit beta I_{CaL}	Loss	Autosomal dominant
BRS type 5	*SCN1B*	$Na_v\beta_1/\beta_{1b}$	Subunit beta I_{Na}	Loss	Autosomal dominant
BRS type 6	*KCNE3*	MiRP2	Subunit beta I_{Ks}/I_{to}	Gain	Autosomal dominant
BRS type 7	*SCN3B*	$Na_v\beta_3$	Subunit beta I_{Na}	Loss	Autosomal dominant

From Issa ZF et al: *Clinical arrhythmology and electrophysiology: a companion to Braunwald's heart disease,* ed 2, Philadelphia, 2012, Saunders.

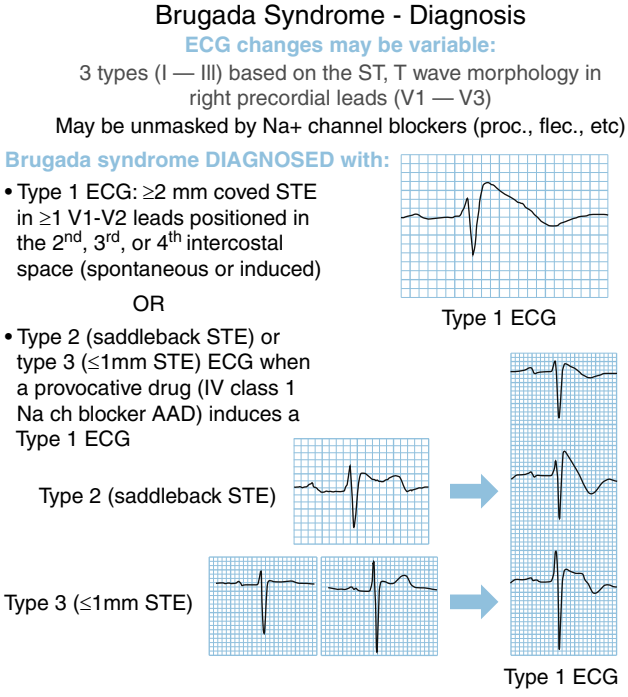

FIG. 1 Brugada electrocardiogram *(ECG)* patterns. A type 1 ECG pattern supports diagnosis of Brugada syndrome. Brugada syndrome can be considered for type 2 or 3 ECG patterns if ECG pattern converts to a type 1 pattern after challenge with a sodium channel *(Na ch)* blocker. *AAD,* Antiarrhythmic drugs; *STE,* ST-segment elevation; *IV,* intravenous. (From Olshansky B et al: *Arrhythmia essentials*, ed 2, Philadelphia, 2017, Elsevier.)

DIFFERENTIAL DIAGNOSIS

A number of diseases can lead to a BRS-like abnormality on the surface ECG, including the following:

- Atypical RBBB
- Early repolarization
- Acute pericarditis
- Acute myocardial infarction or ischemia
- Pulmonary embolism
- Various central and autonomic system abnormalities
- Duchenne muscular dystrophy
- Electrolyte abnormalities such as hyperkalemia and hypercalcemia
- Arrhythmogenic right ventricular cardiomyopathy
- Pectus excavatum

WORKUP

- Clinical history with special emphasis on syncope, palpitations, nocturnal agonal respirations, and family history.
- Echocardiography to rule out structural heart disease. While no structural heart disease is usually apparent, there are some recent reports indicating mild abnormalities in the right ventricle (RV) and left ventricle (LV).
- MRI, especially to rule out ARVC (arrhythmogenic right ventricular cardiomyopathy).
- Electrophysiology study. No consensus exists on the value of arrhythmia induction in predicting future clinical events in individual patients. However, findings such as HV (His ventricular) conduction interval >60 ms and VERP (ventricular effective refractory period) <200 ms during electrophysiology study can help in supporting a diagnosis. Repeated trials have failed to show a predictive power of electrophysiology study, and it still exists as a IIb recommendation. A recent meta-analysis has suggested it may have some utility, and its use in risk stratification remains controversial.
- Laboratory tests are unhelpful. Genetic testing may be helpful for prognosis and family evaluation, but it is not necessary for diagnostic purposes.
- First-degree relatives should obtain ECG and be evaluated for symptoms.
- The following are considered indicators of high risk in an asymptomatic patient:
  1. Spontaneous type 1 ECG at baseline
  2. Presence of fragmented QRS on ECG
  3. RVERP (right ventricular effective refractory period) <200 ms on EPS
  4. Male sex
  5. Spontaneous atrial fibrillation

  Note that family history of sudden death is not considered a high-risk feature in BRS.

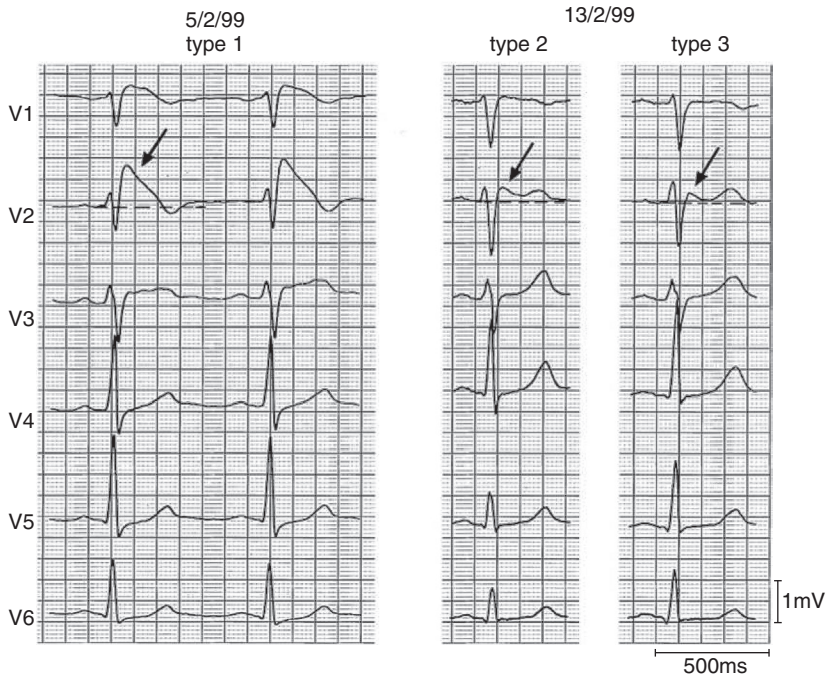

FIG. 2 Electrocardiogram (ECG) changes in Brugada syndrome. ST elevation occurs in the anterior precordial leads, leads V1 and V2. Type 1 (coved) ECGs with 1 mV of ST elevation have the most prognostic significance. (From Strickberger SA et al: AHA/ACCF scientific statement on the evaluation of syncope, *J Am Coll Cardiol* 47:473-484, 2006.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The only effective strategy that prevents sudden cardiac death in BRS is implantable cardioverter-defibrillator (ICD). Currently there are no class I recommendations for primary prevention because clinical events are extremely rare, even in high-risk patients. Fig. 4 depicts the algorithm for clinical decision making regarding recommendation of an ICD.
- Definitive candidates for ICD (class I) are patients who survived SCD or have had sustained VT (secondary prevention).
- ICD can be useful (class IIa) for patients who have type 1 ECG pattern (either spontaneous or after class IC drug test) associated with history of syncope.
- ICD may be considered (class IIb) if there is inducible VF on electrophysiologic (EP) study, but this remains controversial.
- Patients with spontaneous type 1 ECG without syncope or inducible VF on EP study or

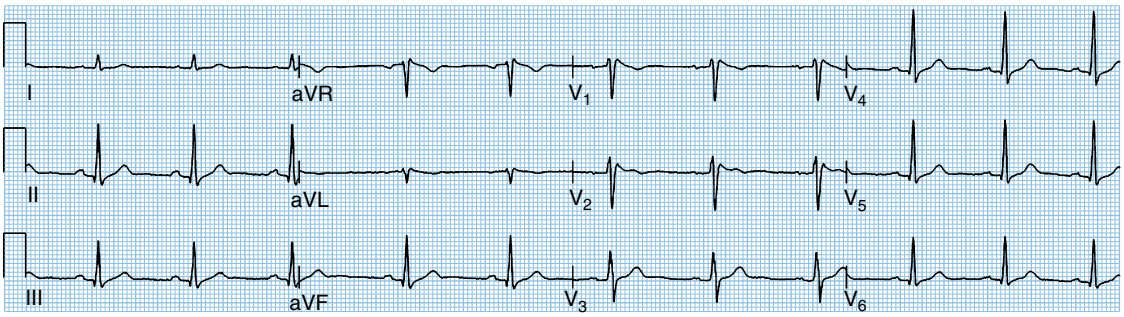

FIG. 3 Type II Brugada pattern electrocardiogram (ECG). This 12-lead ECG shows a type II Brugada pattern in leads V1 and V2. Whereas a type I ECG pattern supports a diagnosis of Brugada syndrome, Brugada syndrome can be considered for type 2 or 3 ECG patterns (see Fig. 1) if the ECG pattern converts to a type 1 pattern after challenge with a sodium channel blocker. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right. (From Olshansky B et al: *Arrhythmia essentials*, ed 2, Philadelphia, 2017, Elsevier.)

TABLE 2 Drugs Used to Unmask Brugada ECG Pattern

Drug	Dose
Ajmaline	1-mg/kg IV infusion over 5 min
Flecainide	2-mg/kg IV infusion over 10 min, maximum 150 mg; or 400 mg PO
Procainamide	10-mg/kg IV infusion over 10 min
Pilsicainide	1-mg/kg IV infusion over 10 min

asymptomatic patients with drug-induced type 1 ECG pattern are considered a lower risk group for SCD, and ICD is not indicated in these patients.

- Radiofrequency catheter ablation of the RV epicardium may be performed for patients with recurrent ventricular arrhythmias and may eliminate the Brugada ECG phenotype. It has also been associated with very low recurrence of arrhythmia in small studies. This has become an accepted therapy for patients with ICD shocks and requires referral to specialized centers.

ACUTE GENERAL Rx

- Isoproterenol (class IIa) may be used for electrical storm.
- Quinidine, which blocks both Ito and IKr currents in the RV epicardium, is used in patients with a history of multiple appropriate ICD shocks, as well as for electrical storms and treatment of supraventricular tachycardia (SVT) in these patients. It is also useful in cases where the patient refuses an ICD implant or when an ICD implant is contraindicated.

REFERRAL

Consultation with a cardiac electrophysiologist is strongly recommended if BRS is suspected.

PEARLS & CONSIDERATIONS

COMMENTS

- The clinical manifestations, such as syncope and SCD, are rare in the pediatric group, but fever can acutely predispose to cardiac arrest. Mean age of presentation is 40 to 45 yr.
- Cardiac events may occur during sleep, at rest, or after a large meal.
- BRS patients should be advised to avoid all drugs that may induce a type 1 ECG pattern and/or be known to trigger ventricular arrhythmias and avoid unnecessary use of drugs (a drug that is not yet identified as potentially dangerous for these patients does not make its use safe). For up-to-date information on this matter, a full list can be found at www.brugadadrugs.org.
- Fever may induce the appearance of a type 1 BRS ECG pattern and may trigger episodes of PVT/VF in BRS patients. In the case of fever, close ECG monitoring is appropriate in combination with lowering of the body temperature.
- The classic ECG changes in BRS can be transient with patients having normal ECGs in between highly abnormal ones.
- The appearance of syncope, seizures, or nocturnal agonal respiration must lead to prompt medical evaluation.
- Family screening for BRS in first-degree relatives is strongly recommended.
- Although participation in sports is not strictly prohibited, competitive training can lead to development of strong vagal tone and subsequent higher risk of clinical events. Hence, participation in sports at a competitive or professional level is not advised.
- Once diagnosed initially by an ECG pattern, all patients must be followed up on a regular basis by an electrophysiologist.

PREVENTION

Identification of patients with BRS, risk stratification, and appropriate screening of family members are paramount to the prevention of SCD. Patients with known BRS should have fevers aggressively treated with antipyretics and avoid drugs associated with drugs that induce a type 1 pattern.

PATIENT & FAMILY EDUCATION

Immediate family members should be notified and be screened for BRS.

BASIC INFORMATION

DEFINITION

Forcible clenching or grinding of the teeth during sleep or wakefulness, often leading to damage of the teeth.

ICD-10CM CODES
G47.63 Sleep related bruxism
F45.8 Other somatoform disorders

EPIDEMIOLOGY & DEMOGRAPHICS

- Occurs in 15% of children and 75% of adults.
- Familial cases have occasionally been described.
- Bruxism often presents between age 10 and 20 yr but may persist throughout life.
- Nocturnal bruxism is noted most often during stages I and II NREM sleep and REM sleep.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Complaints of grinding of teeth from a sleep partner or members of the family are common. In many cases the masticatory system will adapt to the phenomenon, but in severe cases nearly every part of the masticatory system may be damaged. Excessive wearing of dentition is the most common physical finding (Fig. E1). Tender or hypoatrophied masticatory muscles may also be observed.

ETIOLOGY:

- Cause is controversial. Fig. E2 illustrates the cascade of physiologic events in the genesis of sleep bruxism and rhythmic masticatory muscle activity and course of action for management.
- Possible causes include occlusal discrepancies, anatomy of the bony structures of the orofacial region, part of the sleep arousal response, disturbances of the central dopaminergic system, smoking, alcohol, drugs, stress, and personality.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dental compression syndrome
- Temporomandibular joint disorders
- Chronic orofacial pain disorders
- Oral motor disorders
- Malocclusion

WORKUP

- History should have an emphasis on sleep habits, including excessive snoring, pain in the temporal mandibular region, interview with close family members, health habits, personality quirks.
- Physical examination of the teeth and masticatory muscles is mandatory.
- Sleep studies in selected cases may be helpful.

LABORATORY TESTS

None indicated unless a systemic disease is suspected (e.g., infection, autoimmune disorder)

IMAGING STUDIES

X-ray studies of teeth and temporomandibular joints

TREATMENT

NONPHARMACOLOGIC THERAPY

Biofeedback, psychological counseling, and elimination of harmful health habits have been used with limited success.

GENERAL Rx

- Oral splints (Fig. E3); night guard to protect teeth may be useful
- Correction of malocclusion
- Pain management (e.g., gabapentin, ibuprofen)
- Medication to relieve anxiety and improve sleep (e.g., benzodiazepine or trazodone at bedtime)
- Local injections of botulinum toxin into masseter muscles to prevent dental and temporomandibular joint complications

DISPOSITION

Referral to dentist mandatory if damage to teeth evident

PEARLS & CONSIDERATIONS

- Like any poorly understood disease, treatment is often unsatisfactory and subject to quackery.
- Both diurnal and nocturnal bruxism may be associated with various movement and degenerative disorders (e.g., Huntington disease, oromandibular dystonia) and are quite common in children with cerebral palsy and mental retardation.

Budd-Chiari Syndrome PTG ALG

BASIC INFORMATION

DEFINITION

Budd-Chiari syndrome (BCS) is a rare disorder defined by the obstruction of hepatic venous outflow anywhere from the small hepatic veins to the junction of the inferior vena cava (IVC) and the right atrium. Primary BCS is defined by endoluminal obstruction as seen in thromboses, phlebitis, or webs. Secondary BCS occurs when the obstruction is caused by compression or invasion by a lesion originating outside of the veins (tumor, abscess, cyst, etc.). It can also be a postoperative complication of orthotopic liver transplantation (OLT).

SYNONYMS

BCS
Hepatic vein thrombosis
Obliterative endophlebitis of the hepatic veins
IVC thrombosis
Chiari-Budd syndrome
Budd syndrome
Chiari disease
Rokitansky disease

ICD-10CM CODE
I82.0 Budd-Chiari syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Males: 2.0/1 million persons per yr
Females: 2.2/1 million persons per yr

PREDOMINANT SEX:

- In Western countries, women are more commonly affected (approximately 2/3 of cases).
- In Asia, men are slightly more affected (approximately 1.5/1).

PREDOMINANT AGE:

- In Western countries, presentation is usually in the third and fourth decades of life, with the median age being 35 to 50 yr.
- In Asia, presentation is usually at a median age of 36 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical presentation and characteristics vary with geography. The classic presentation of Budd-Chiari syndrome includes hepatomegaly, ascites, and right upper quadrant pain. In Africa and South Asia, intravascular webs are more often associated with IVC thrombosis with a stronger association with subsequent liver cirrhosis and hepatocellular carcinoma. In the U.S., BCS is more commonly associated with primary myeloproliferative disorders and underlying hypercoagulable states. Underlying factors that contribute to BCS can be identified in more than 80% of cases; multiple causative factors are identified in up to 50% of cases.

- Clinical manifestations can be caused by complete or partial occlusion of any or all of the three major hepatic veins or the inferior vena cava.
- Presentation is variable according to the degree, location, acuity of obstruction, and presence of collateral circulation:
  1. Fulminant/acute (25%): Severe right upper quadrant abdominal pain, fever, nausea, vomiting, mild jaundice, hepatomegaly, transudative and intractable ascites, marked elevation in serum aminotransferases (AST/ALT >5 times the upper limit of normal), elevation of alkaline phosphatase to 300 to 400 IU/L, serum-ascites albumin gradient ≥1.1 with total protein >2.5 g/dl, coagulopathy (usually international normalized ratio [INR] >1.5), variceal bleeding, encephalopathy within 8 wk of onset of jaundice, renal failure. Biopsy, if performed, would reveal hepatic necrosis. Early recognition and treatment are essential for survival; a slow decrease in ALT is associated with poor survival.
  2. Subacute/chronic (60%): Vague abdominal discomfort, gradual progression to caudate lobe hypertrophy with atrophy of the rest of the liver, portal hypertension with or without cirrhosis and its sequelae, transudative ascites, lower-extremity edema, esophageal varices, splenomegaly, coagulopathy, mild to moderate elevation in aminotransferases, bilirubin and alkaline phosphatase, hepatorenal syndrome, hepatopulmonary syndrome, and rarely, encephalopathy; biopsy, if performed, could reveal minimal hepatic necrosis.
  3. Asymptomatic (up to 20%): Usually discovered incidentally by abnormal liver function tests or imaging attained for other reasons.

ETIOLOGY:

Approximately 80% to 87% of patients have one prothrombotic risk factor, and approximately 50% have multiple.

- Primary myeloproliferative diseases: Up to 53% of BCS patients have a primary myeloproliferative disease and polycythemia vera is responsible for 10% to 40% of these cases.
  1. Essential thrombocythemia and idiopathic myelofibrosis are less common causes.
  2. *JAK2* mutations are implicated in cases of idiopathic BCS (identified in 25% to 60% of cases).
- Hypercoagulable states (inherited and acquired) often coexist with other causes.
  1. Anticardiolipin antibodies (up to 25%)
  2. Hyperhomocysteinemia (22%)
  3. Paroxysmal nocturnal hemoglobinuria (5% to 19%)
  4. Factor V Leiden (25%)
  5. Factor II gene mutation (5%)
- Protein C, protein S, and antithrombin III deficiency are difficult to interpret because the presence of liver disease may confound results. However, they account for 4.0%, 3.0%, and 3.0% of BCS, respectively.
- Heterozygosity for *G20210A* prothrombin gene mutation, methylenetetrahydrofolate reductase (MTHFR) mutation, Tet methylcytosine dioxygenase 2 mutation, and calreticulin mutation may be seen in BCS.
- Pregnancy and oral contraceptive pills are also predisposing factors to develop BCS.
- Malignancy causing external compression or invasion of vascular structures (up to 10% of cases).
  1. Most commonly due to hepatocellular carcinoma but also can be due to neoplasms of the kidney, adrenal gland, pancreas, stomach, lung and sarcomas of the right atrium, inferior vena cava, and hepatic veins.
- Rare but reported: Sickle cell anemia, infections with liver abscess, hydatid cyst (echinococcosis), schistosomiasis, sarcoidosis, Behçet disease, membranous webs of IVC or hepatic veins (more common in Africa and South Asia, can be congenital or acquired secondary to underlying myeloproliferative disorder), abdominal trauma, liver torsion, granulomatous venulitis, ulcerative colitis, celiac disease, systemic lupus erythematous, minimal change nephrotic syndrome, neurofibromatosis, α-1 antitrypsin deficiency, hypereosinophilic syndrome, idiopathic (10% to 25%).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hepatitis from ischemia, viral infection, toxin, alcohol
- Cholecystitis
- Hepatic veno-occlusive disease (sinusoidal obstruction syndrome)
- Congestive hepatopathy, also known as *cardiac cirrhosis*, from tricuspid regurgitation, right atrial myxoma, constrictive pericarditis
- Cirrhosis from any etiology

LABORATORY TESTS

- Assessment of liver injury and function: Serum aminotransferases, alkaline phosphatase, prothrombin time (PT), albumin, bilirubin.
- Exclusion of another form of liver disease: Viral hepatitis panel, autoantibodies (antinuclear antibody, anti–smooth muscle antibody, anti-mitochondrial antibody), iron studies, ceruloplasmin, and α-1 antitrypsin.
- Ascites protein content ≥2.5 g/dl and serum ascites albumin gradient >1.1 g/dl are suggestive of transudative ascites from BCS or cardiac ascites.
- Evaluation for underlying myeloproliferative disorder and hypercoagulable state: CBC, bone marrow biopsy, tests for hypercoagulable states (Factor V Leiden, prothrombin gene *G20210A* mutation, protein C, protein S, antithrombin deficiencies, antiphospholipid syndrome, and paroxysmal nocturnal hemoglobinuria). Protein C, protein S, and antithrombin deficiencies may be difficult to

interpret in the setting of liver dysfunction, but levels <20% of normal are suggestive of a true deficiency; thrombophilia screening for the JAK2 V617F mutation, hyperhomocysteinemia, and MTHFR C677T mutation may be useful if no other cause for myeloproliferative disorders or hypercoagulable states are identified.

IMAGING STUDIES

- Diagnosis of BCS is made by radiographic imaging (Figs. E1, E2, and E3).
- Doppler ultrasonography is the first-line test. Diagnostic sensitivity and specificity are 85% to 90%. Findings include large hepatic vein with an absent flow signal, or with reversed or turbulent flow; large intrahepatic or subcapsular collateral vessels; enlarged, stenotic, thickened, or tortuous hepatic veins; spider web pattern near hepatic vein ostia and associated absent flow in that region; caudate lobe hypertrophy (as the caudate lobe has an alternate blood supply through anastomoses); flattened or absent hepatic venous waveform without fluttering; hyperechoic cord replacing a normal vein.
- MRI with gadolinium contrast is the second-line test. It is superior to contrast-enhanced CT (Fig. E4) with a sensitivity and specificity of approximately 90%, and it is preferred in younger patients due to the lack of radiation. Findings include obstructed hepatic veins or IVC, large intrahepatic or subcapsular collaterals, and caudate lobe hypertrophy. MRI is beneficial to visualize the entire length of the IVC and distinguish between acute, subacute, and chronic BCS. Three-dimensional contrast-enhanced magnetic resonance angiography (MRA; see Fig. 5) rivals hepatic venography in sensitivity.
- Contrast-enhanced CT may reveal similar findings as Doppler ultrasound as well as delayed or absent filling of the hepatic veins, parenchymal opacification of the liver, narrowing and/or compression of the inferior vena cava, and caudate lobe hypertrophy. Contrast enhancement localizes more centrally than peripherally and has a patchy and flea-bitten appearance. The use of CT is limited given that in almost 50% of patients, the test is indeterminate or a false-positive. Ultrasonography is more accurate than CT for detecting lesions in the hepatic veins and IVC.
- CT image reconstruction of vasculature is becoming more available.
- Venography: Although it is the gold standard, it is not essential for diagnosis, and it should be performed when other noninvasive imaging tests are nondiagnostic in the setting of strong clinical suspicion for BCS. Measurement of pressure gradients can help predict success of percutaneous or surgical shunt intervention. Confirms the pathognomonic web pattern caused by collateral venous flow.
- Liver biopsy: Not necessary to diagnose BCS but may be helpful in patients with cirrhosis in whom the diagnosis remains uncertain and is critical for differentiating from hepatic venoocclusive disease or congestive hepatopathy. Findings include hepatic congestion, hepatocyte necrosis and fibrosis in centrilobular areas, and compensatory nodular regenerative hyperplasia with progression to fibrosis and cirrhosis. In advanced BCS, infarction caused by concomitant thrombosis of the intrahepatic, extrahepatic, and portal veins may be seen. There are conflicting studies regarding the association of histologic findings and prognosis.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Goal of therapy is decompression of hepatic congestion.
- In general, therapeutic procedures should be introduced by order of increasing invasiveness based on response/failure to therapy rather than disease severity. Fig. 6 illustrates a treatment algorithm for patients with Budd-Chiari syndrome.
- Hypercoagulable states should be investigated in all patients.

ACUTE GENERAL Rx

- Anticoagulation, first with low-molecular-weight heparin (LMWH), followed by warfarin, even in the absence of an underlying hypercoagulable disorder. Recent research also suggests that using direct-acting oral anticoagulants in BCS is safe and effective.
- In situ thrombolysis: Can be successful when performed in patients with recently thrombosed veins (within 2 to 3 wk after symptom onset) that are well defined on venography. Mature clots are nonresponsive to thrombolysis, and bleeding risk is high if portal hypertension has developed.
- Balloon angioplasty: Complicated by 50% restenosis rate within 2 yr; effective when membranous webs or short segment hepatic vein stenosis are the etiology.
- Stenting: May improve long-term patency rates to 90%, but if placed above the intrahepatic IVC, may complicate future liver transplantation.
- Transjugular intrahepatic portosystemic shunt (TIPS) (Fig. 7): Indicated with diffuse

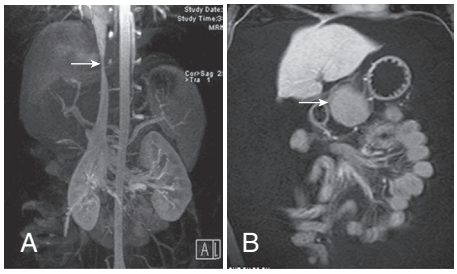

FIG. 5 Magnetic resonance venogram. A, Intravenous cholangiography (IVC) obstruction *(arrow)* at the level of the caudate. **B,** Hypertrophic caudate lobe *(arrow)*. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, WB Saunders.)

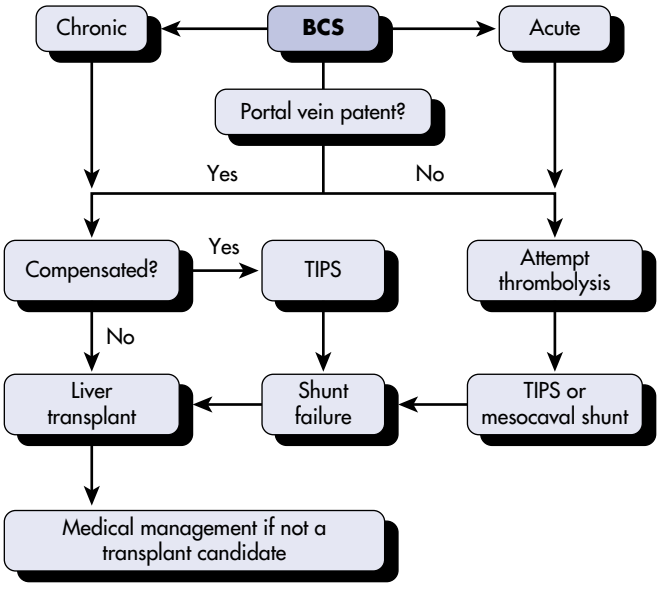

FIG. 6 Treatment algorithm for patients with Budd-Chiari syndrome (BCS). *TIPS,* Transjugular intrahepatic portosystemic shunt. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

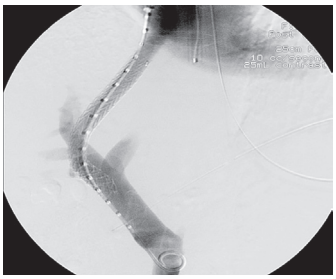

FIG. 7 Transjugular intrahepatic portosystemic shunt extending from the right portal vein into the right atrium. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

hepatic vein thrombosis, refractory ascites, recurrent variceal bleeding and progressive liver failure. Polytetrafluoroethylene (ePTFE)-coated stents have improved TIPS-patency rates, especially in patients with underlying hypercoagulable defects with a 76% 10-yr survival rate.
- Surgical portal systemic shunts: Indicated when angioplasty and stenting have failed and when complications from portal hypertension are also present. This option is no longer common practice and provides no survival benefit.
- Liver transplant may be indicated in patients with cirrhosis or fulminant hepatic failure and in patients who fail to respond to TIPS; 10-yr survival is reported to range between 69% and 84%.
- Supportive measures.

CHRONIC Rx

- Lifelong anticoagulation: Warfarin therapy, with a target INR of 2 to 3 or low-molecular-weight heparin, lessens, but does not completely prevent, recurrence. Anticoagulation should be continued permanently unless the patient has an adverse event to anticoagulation, the obstruction is because of an anatomic cause that has been corrected, or anticoagulation is contraindicated.
- In patients with an underlying myeloproliferative disorder, first-line treatment is with hydroxyurea and aspirin.
- Treat liver dysfunction and complications related to portal hypertension such as ascites and variceal bleeding.
- Invasive interventions should be reserved for symptomatic patients who do not improve with medical therapy.
- Manage shunt thrombosis; which is a common complication.
- Liver transplantation is another treatment option with a 71% to 89% survival rate at 5 yr; up to 27% recurrence of BCS after transplant has been recognized.
- Monitor for development of hepatocellular carcinoma and transformation of myeloproliferative disease in patients with long-standing, well-controlled BCS and post-transplant lymphoma in orthotopic liver transplantation (OLT) recipients.

DISPOSITION

Prognosis is variable and depends on multiple factors, including time to recognition and treatment, etiology, acuity, the type of intervention, and the condition of the patient at the time of treatment. Overall mortality rates are decreasing with the use of anticoagulation and early diagnosis of asymptomatic cases. Given numerous therapeutic options, the survival rate is 90%, 83%, and 72% at 1, 5, and 10 yr from diagnosis.

- A prognostic index called the *Rotterdam BCS Index* has been described: 1.27 × Encephalopathy + 1.04 × Ascites + 0.72 × PT + 0.004 × Bilirubin.
  1. Encephalopathy and ascites are scored as 1 for present or 0 as absent, and PT is scored as greater (1) or less than (0) an INR of 2.3.
  2. An index of <1.1 correlates to low risk (5-yr survival rate, 89%), 1.1 to 1.5 with intermediate risk (5-yr survival rate, 74%), and >1.5 with high risk (5-yr survival rate, 42%).
- There is also the *BCS-TIPS PI score*, which is a prognostic index for survival 1 yr after TIPS: Age (yr) × 0.08 + bilirubin × 0.16 + INR × 0.63.
  1. Seven is the most specific discriminative factor, with those scoring above 7 necessitating emergent OLT as the first-line treatment.

REFERRAL

Fulminant presentations should immediately be referred to a center capable of liver transplantation. All cases benefit from referral to a hepatologist, a hematologist, an interventional radiologist, and a surgeon specializing in hepatobiliary disease.

PEARLS & CONSIDERATIONS

COMMENTS

- Look for one or more underlying causes, especially hypercoagulable or hematologic disorders, and malignancies or space-occupying lesions that may compress or invade the hepatic outflow tract.
- Myeloproliferative disorders are most common.
- Diagnosis relies on imaging; beginning with Doppler ultrasound.
- Treatment with anticoagulation comes first; followed by invasive interventions as needed. Prophylaxis of portal hypertension can reduce the risk of major bleeding associated with anticoagulation therapy.
- Referral for liver transplantation may be necessary.
- Prognostic indices can assist in management and estimate survival rates.

PREVENTION

In the setting of known risk factors, such as a hypercoagulable state or myeloproliferative disorder, any additional risks, such as smoking or oral contraceptive therapy, should be avoided.

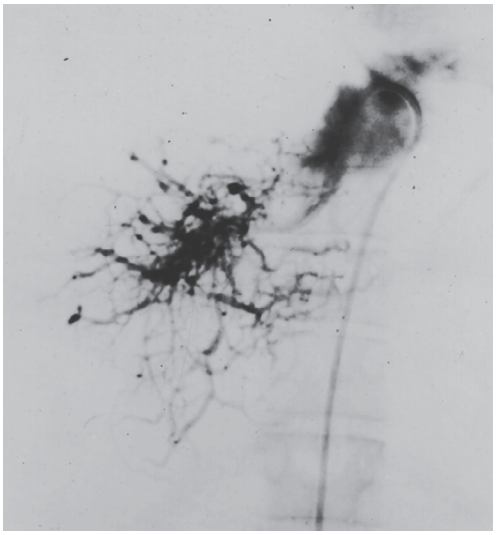

FIG. E1 Budd-Chiari syndrome. A catheter has been passed retrogradely into a right hepatic vein. Injection of contrast medium has outlined an extensive fine network of collateral vessels. This "spider web" appearance is pathognomonic of Budd-Chiari syndrome. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

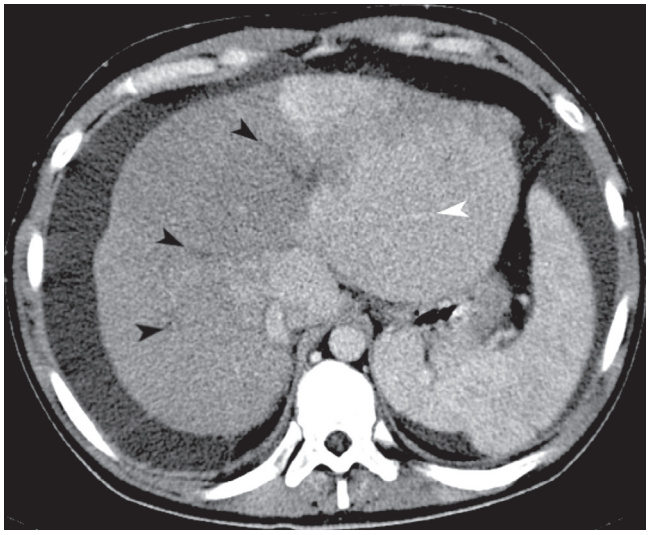

FIG. E2 Acute Budd-Chiari syndrome. On portal phase CT, most of the caudate and left lobe of the liver has enhanced normally and the left hepatic vein can just be seen *(white arrowhead)*, but the right lobe has abnormally low attenuation, and the middle and right hepatic vein branches are attenuated and have failed to opacify *(black arrowheads)*. Ascites is present. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

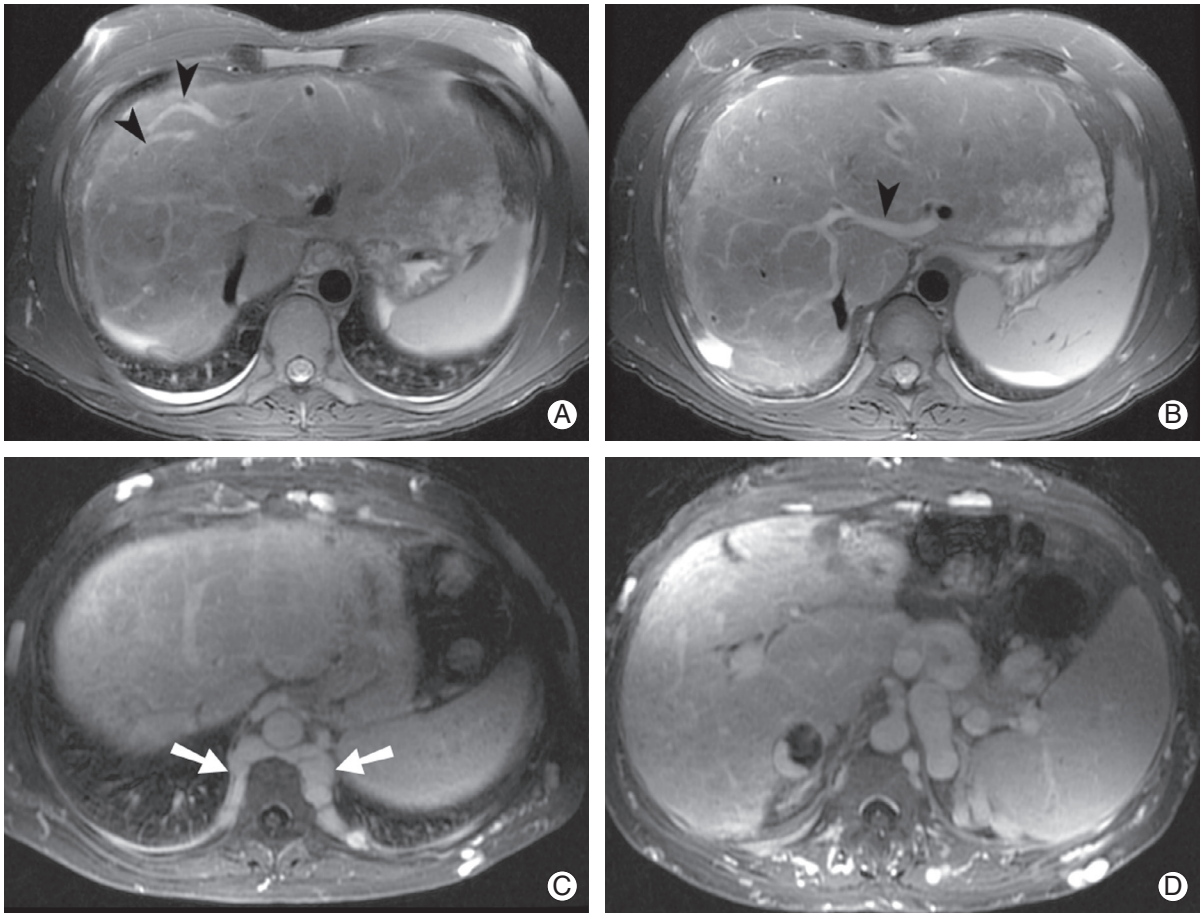

FIG. E3 Chronic Budd-Chiari syndrome. Changes in a patient with previous occlusion of the right and middle hepatic veins include hypertrophy of the left lobe and numerous abnormal curved venous channels *(arrowheads)* shown on multishot T2-weighted (T2W) fast spin echo (FSE) imaging at two different levels **(A, B).** In a separate patient after occlusion of the inferior vena cava (IVC) by thrombus **(C, D),** there are enlarged retroperitoneal and azygos system veins *(arrows)*, as well as numerous superficial collateral veins, shown on postgadolinium T1-weighted (T1W) MRI. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

FIG. E4 Computed tomography scan of Budd-Chiari syndrome. The appearances are not immediately diagnostic for the nonexpert, and infiltrative disease is sometimes suspected. (From Forbes A et al [eds]: *Atlas of clinical gastroenterology*, ed 3, St Louis, 2005, Mosby.)

BASIC INFORMATION

DEFINITION

Bulimia nervosa is a prolonged illness characterized by a specific psychopathology. According to the *Diagnostic and Statistical Manual of Mental Disorders,* 5th edition (DSM-5), bulimia nervosa can be diagnosed by:

- (A) Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following:
  1. Eating, in a discrete period of time, an amount of food that is definitely larger than what most individuals would eat in a similar period of time under similar circumstances.
  2. A sense of lack of control over eating during the episode.
- (B) Recurrent inappropriate compensators/behaviors in order to prevent weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, or other medications; fasting; or excessive exercise. (C) The binge eating and inappropriate compensatory behaviors both occur, on average, at least once a week for 3 mo. (D) Self-evaluation is unduly influenced by body shape and weight. (E) The disturbance does not occur exclusively during episodes of anorexia nervosa.

ICD-10CM CODE
F50.2 Bulimia nervosa

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE: Affects 1% to 3% of female adolescents and young adults
PREDOMINANT SEX: Female:male ratio of 10:1
PREDOMINANT AGE: Adolescence to young adulthood; mean age of onset 17 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Parotid and salivary gland swelling
- Scars on the back of the hand and knuckles (Russell sign) from rubbing against the upper incisors when inducing vomiting
- Eroded enamel, particularly on the lingual surface of the upper teeth; pyorrhea and other gum disorders possible
- Petechial hemorrhages of the cornea, soft palate, or face possibly noted after vomiting
- Loss of gag reflex, well-developed abdominal musculature
- Often no emaciation; normal physical examination possible

ETIOLOGY

- Etiology is unknown but likely multifactorial (sociocultural, psychological, familial factors).
- Bulimia is much more common in Western societies, where there is a strong cultural pressure to be slender.
- According to the American Psychiatric Association, patients with eating disorders display a broad range of symptoms that occur along a continuum between those of anorexia nervosa and bulimia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Schizophrenia
- Gastrointestinal disorders
- Neurologic disorders (seizures, Kleine-Levin syndrome, Klüver-Bucy syndrome)
- Brain neoplasms
- Psychogenic vomiting

WORKUP

- The following questions are useful to screen patients for bulimia:
  1. "Are you satisfied with your eating habits?"
  2. "Do you ever eat in secret?"
- Answering "no" to the first question and/or "yes" to the second question has 100% sensitivity and 90% specificity for bulimia. The SCOFF questionnaire can also be used as a screening tool for eating disorders (see "Anorexia Nervosa").
- According to the DSM-5, the level of severity is based on the frequency of inappropriate compensatory behaviors and may be increased to reflect other symptoms and degree of functional disability, as noted below:
  1. Mild: An average of 1 to 3 episodes of inappropriate compensatory behaviors per week
  2. Moderate: An average of 4 to 7 episodes of inappropriate compensatory behaviors per week
  3. Severe: An average of 8 to 13 episodes of inappropriate compensatory behaviors per week
  4. Extreme: An average of ≥14 inappropriate compensatory behaviors per week
- Table E1 describes eating and weight control habits commonly found in children and adolescents with an eating disorder.

LABORATORY TESTS

- Electrolyte abnormalities from vomiting (hypokalemia and metabolic alkalosis) or diarrhea from laxative abuse (hypokalemia and hyperchloremic metabolic acidosis)
- Hyponatremia, hypocalcemia, hypomagnesemia (caused by laxative abuse)
- Elevated cortisol, decreased luteinizing hormone, decreased follicle-stimulating hormone

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cognitive behavioral therapy, particularly interpersonal therapy to control abnormal behaviors
- Use of food diaries, nutritional counseling, and planning meals at least 1 day in advance are useful measures to counter abnormal eating behaviors
- Correction of electrolyte abnormalities

ACUTE GENERAL Rx

- Selective serotonin reuptake inhibitors are generally considered to be the safest medication option in these patients. They are useful in severely depressed patients and in those who do not benefit from cognitive behavioral therapy.
- Prompt recognition and treatment of complications:
  1. Ipecac cardiotoxicity from laxative abuse
  2. Electrolyte abnormalities (see "Laboratory Tests")
  3. Esophagitis and Mallory-Weiss tears; esophageal rupture from repeated vomiting
  4. Aspiration pneumonia and pneumomediastinum
  5. Menstrual irregularities (including amenorrhea)
  6. Gastrointestinal abnormalities: Acute gastric dilation, pancreatitis, abdominal pain, constipation

CHRONIC Rx

- Psychotherapy continued for years and focused specifically on self-image and family and peer interactions is an integral part of successful recovery.
- Family therapy is also recommended, especially in younger patients.

DISPOSITION

Course is variable and marked by frequent recurrence of exacerbations.

REFERRAL

- In addition to the primary care physician, the multidisciplinary team should include a dietician, a psychiatrist, and a family therapist.
- Hospitalization should be considered for patients with severe electrolyte abnormalities or those with suicidal thoughts.

PEARLS & CONSIDERATIONS

COMMENTS

- Bulimia has a close association with depression, bipolar disorder, obsessive-compulsive disorder, alcoholism, and substance abuse.
- Bulimia should be considered in all patients (especially adolescents) with unexplained hypokalemia and metabolic alkalosis.

Bulimia (Patient Information)
Anorexia Nervosa (Related Key Topic)
Binge Eating Disorder (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

TABLE E1 Eating and Weight Control Habits Commonly Found in Children and Adolescents with an Eating Disorder

	Prominent Features		Clinical Comments Regarding Eating Disorder Habits	
Habit	**Anorexia Nervosa**	**Bulimia Nervosa**	**Anorexia Nervosa**	**Bulimia Nervosa**
Overall intake	Inadequate energy (calories), although volume of food and beverages may be high due to very low caloric density of intake due to "diet" and nonfat choices	Variable, but calories normal to high; intake in binges often "forbidden" food or drink that differs from intake at meals	Consistent inadequate caloric intake leading to wasting of the body	Inconsistent balance of intake, exercise, and vomiting, but severe caloric restriction is short-lived
Food	Counts and limits calories, especially from fat; emphasis on "healthy food choices" with reduced caloric density; monotonous, limited "good" food choices, often leading to vegetarian or vegan diet; strong feelings of guilt after eating more than planned leads to exercise and renewed dieting	Aware of calories and fat, but less regimented in avoidance than AN; frequent dieting interspersed with overeating, often triggered by depression, isolation, or anger	Obsessive-compulsive attention to nutritional data on food labels and may have "logical" reasons for food choices in highly regimented pattern, such as sports participation or family history of lipid disorder	Choices less structured, with more frequent diets
Beverages	Water or other low- or no-calorie drinks; nonfat milk	Variable, diet soda common; may drink alcohol to excess	Fluids often restricted to avoid weight gain	Fluids ingested to aid vomiting or replace losses
Meals	Consistent schedule and structure to meal plan; reduced or eliminated caloric content, often starting with breakfast, then lunch, then dinner; volume can increase with fresh fruits, vegetables, and salads as primary food sources	Meals less regimented and planned than in AN; more likely impulsive and unregulated, often eliminated following a binge-purge episode	Rigid adherence to "rules" governing eating leads to sense of control, confidence, and mastery	Elimination of a meal following a binge-purge only reinforces the drive for binge later in the day
Snacks	Reduced or eliminated from meal plan	Often avoided in meal plans, but then impulsively eaten	Snack foods removed early because "unhealthy"	Snack "comfort foods" can trigger a binge
Dieting	Initial habit that becomes progressively restrictive, although often appearing superficially "healthy"; beliefs and "rules" about the patient's idiosyncratic nutritional requirements and response to foods are strongly held	Initial dieting gives way to chaotic eating, often interpreted by the patient as evidence of being "weak" or "lazy"	Distinguishing between healthy meal planning with reduced calories and dieting in ED may be difficult	Dieting tends to be impulsive and short-lived, with "diets" often resulting in unintended weight gain
Binge eating	None in restrictive subtype, but an essential feature in binge-purge subtype	Essential feature, often secretive; shame and guilt prominent afterward	Often "subjective" (more than planned but not large)	Relieves emotional distress, may be planned
Exercise	Characteristically obsessive-compulsive, ritualistic, and progressive; may excel in dance, long-distance running	Less predictable; may be athletic, or may avoid exercise entirely	May be difficult to distinguish active thin vs. ED	Males often use exercise as means of "purging"
Vomiting	Characteristic of binge-purge subtype; may chew then spit out, rather than swallow, food as a variant	Most common habit intended to reduce effects of overeating; can occur after meal as well as a binge	Physiologic and emotional instability prominent	Strongly "addictive" and self-punishing, but does not eliminate calories ingested—many still absorbed
Laxatives	If used, generally to relieve constipation in restrictive subtype, but as a cathartic in binge-purge subtype	Second most common habit used to reduce or avoid weight gain, often used in increasing doses for cathartic effect	Physiologic and emotional instability prominent	Strongly "addictive," self-punishing, but ineffective means to reduce weight (calories are absorbed in the small intestine, but laxatives work in the colon)
Diet pills	Very rare, if used; more common in binge-purge subtype	Used to either reduce appetite or increase metabolism	Use of diet pills implies inability to control eating	Control over eating may be sought by any means

AN, Anorexia nervosa; *BN,* bulimia nervosa; *ED,* eating disorder.

BASIC INFORMATION

DEFINITION

Bullous pemphigoid (BP) is a chronic, autoimmune, subepidermal blistering disease commonly seen in the elderly. It is the most common of the acquired bullous autoimmune dermatoses. Other related diseases in the pemphigoid nosology include mucous membrane or cicatricial pemphigoid (MMP), anti-laminin 332 pemphigoid, Brusting-Perry pemphigoid, anti-laminin gamma-1 (anti-p200) pemphigoid, and dermatitis herpetiformis. Some consider linear IgA bullous dermatosis (LABD) and epidermolysis bullosa acquisita (EBA) to be forms of MMP. These diseases are all characterized by subepidermal loss of adhesion in hemidesmosomes of the basement membrane zone.

SYNONYMS

BP
Pemphigoid

ICD-10CM CODE
L12.0 Bullous pemphigoid

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common of the autoimmune bullous dermatoses in developed countries.
- Median age of onset is 75 to 80 yr, with rate of incidence increasing above age 70 yr and reaching a maximum above age 90 yr.
- Incidence varies depending on geographic location: Estimated at 24 cases per 1 million person-yr in the U.S. and ranging from 2.4 to 42.8 cases per 1 million person-yr in Europe.
- Bullous pemphigoid is very rare in children.
- Sex predilection varies by study, with some demonstrating no significant difference in incidence and others showing a general trend of female predilection in patients under age 75 but increased frequency in males over age 80.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

HISTORY:

- Two stages:
  1. Non-bullous phase: Starts as excoriated, eczematous, papular, or **urticarial plaques** characterized by extreme pruritus
  2. Bullous phase: Occurs days to months later and is characterized by formation of **tense blisters** (Fig. E1) that only become flaccid after rupture

PHYSICAL FINDINGS:

- Anatomic distribution:
  1. Flexor surfaces of the arms and legs, groin, axilla, chest, and abdomen; generally spares the head and neck
  2. Mucosal membrane involvement seen in 10% to 40% of patients (when present, typically involves the oral mucosa with sparing of the lips)
- Lesion configuration:
  1. May be localized in up to 30% of cases (extremities most common) or become generalized
  2. Lesions can have an annular or figurate pattern and may resemble erythema multiforme
- Lesion morphology:
  1. Tense blisters (bullae) measuring 1 to 3 cm in diameter and filled with clear or bloody fluid (Fig. E1) on either normal or urticarial skin are characteristic
  2. Absoe Hansen negative: No spread of eroded bases as blisters rupture; and also Nikolsky sign negative
  3. Heal without scarring but may leave postinflammatory hyperpigmentation or, more rarely, milia

ETIOLOGY

- Autoimmune disease with immunoglobulin (Ig) G and/or C3 complement targeting hemidesmosomal antigens (BP180 or BP230) located in the epidermal basement membrane zone
- Drug-induced pemphigoid, although uncommon, can occur in patients taking penicillamine, captopril (and rarely other angiotensin-converting enzyme inhibitors), penicillin and its derivatives, furosemide, sulfhydryl- or phenol-containing cephalosporins, sulfasalazine, acetylsalicylic acid, nonsteroidal antiinflammatory drugs (NSAIDs), dipeptidyl peptidase IV inhibitors (gliptins), TNF-α inhibitors, and vaccines
- Additionally, there are several reports of UV- or radiation therapy-induced BP
- BP patients are significantly more likely to have neurologic disease, with multiple sclerosis having the strongest association; unipolar or bipolar disorder, dementia, stroke and Parkinson disease are also associated with BP

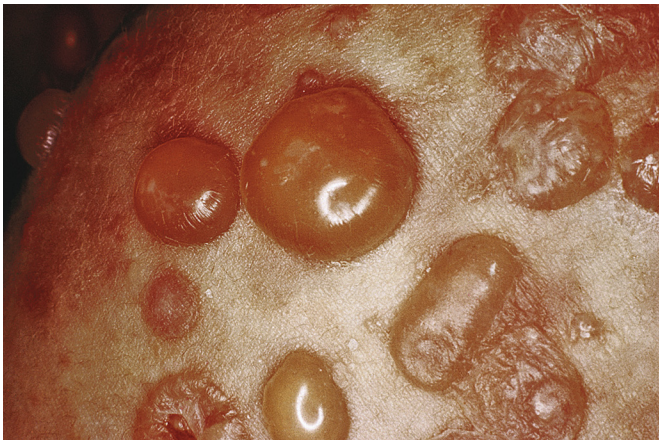

FIG. E1 Bullous pemphigoid. Large, tense bullae are seen on the lower region of the abdomen in this 13-year-old boy. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Philadelphia, Elsevier.)

DIAGNOSIS

Diagnosis is based on a combination of clinical, histologic, and immunofluorescence findings. Direct immunofluorescence (DIF) microscopy is the gold standard. A detailed medical history, including date of onset, evolution of lesions, presence of pruritus, associated neurologic or psychiatric diseases and malignancies, and medication history over the past 6 months, should be obtained. BP should be high on the differential for an elderly patient presenting with generalized itch or nonscarring lesions without mucosal involvement and sparing the head and neck. The diagnosis can be confirmed with the following steps:

1. Validated BP criteria: Three of four clinical features (age >70, nonscarring, no mucosal involvement, absence of bullous lesions on head and neck) plus evidence of linear IgG and/or C3 deposits along basement membrane on DIF microscopy
2. Skin biopsy: Evidence of IgG anti-basement membrane autoantibodies on indirect immunofluorescence (IIF) microscopy
3. Skin biopsy: Evidence of anti-BP180 IgG and/or anti-BP230 IgG autoantibodies on enzyme-linked immunosorbent assay (ELISA)

DIFFERENTIAL DIAGNOSIS

- Bullous arthropod bites
- Linear IgA bullous dermatosis
- Dermatitis herpetiformis
- Anti-laminin gamma-1 (anti-p200) pemphigoid
- Brunsting-Perry pemphigoid
- Bullous systemic lupus erythematosus
- Mucous membrane or cicatricial pemphigoid
- Epidermolysis bullosa acquisita
- Pemphigoid gestationis
- Bullous erythema multiforme
- Generalized fixed drug eruption
- Impetigo
- Porphyria cutanea tarda
- Bullous lichen planus
- Pemphigus vulgaris
- Paraneoplastic pemphigus
- Table E1 compares some of these immunobullous diseases

LABORATORY TESTS

- Histology of lesional skin

TABLE E1 Immunobullous Skin Diseases

Immunobullous Disease	Clinical Presentation	Serum Autoantibodies	Targeted Protein or Structure	Tissue Immunofluorescence*
Pemphigus Dermatoses				
Pemphigus vulgaris	Flaccid bullae on noninflamed skin, crusting, positive Nikolsky sign;† commonly affects scalp, chest, intertriginous areas, and oral mucosa	IgG epithelial cell surface; correlates with disease activity	Desmoglein 3 and desmoglein 1 of the desmosome	Epidermal IgG and C3 cell surface staining
Pemphigus foliaceous	Superficial bullae, erosions, and scale with crusting, positive Nikolsky sign†	IgG epithelial cell surface; correlates with disease activity	Desmoglein 1 of the desmosome	Epidermal IgG and C3 cell surface staining
Paraneoplastic pemphigus	Flaccid bullae, lichenoid or erythema multiforme-like, usually involves mucosa, often extensively includes esophageal and respiratory areas	IgG epithelial cell surface and basement membrane zone (staining on rodent bladder epithelium is characteristic); correlates with disease activity	Desmoglein 3, desmoplakin 1, desmoplakin 2, BPAG1, envoplakin, periplakin, other proteins of the desmosome and hemidesmosome	Epidermal IgG and C3 cell surface and basement membrane zone staining
IgA pemphigus	Flaccid bullae, similar to pemphigus vulgaris	IgA epithelial cell surface; correlates with disease activity	Desmocollin 1 of the desmosome	Epidermal IgA cell surface staining
Pemphigoid Dermatoses				
Bullous pemphigoid	Tense bullae, often on urticarial base, prominent pruritus	IgG basement membrane zone, epidermal	BPAG2, BPAG1, hemidesmosome, lamina lucida	Linear basement membrane zone IgG and C3
Mucous membrane or cicatricial pemphigoid	Tense bullae and erosions, scarring sequelae	IgG basement membrane zone, epidermal	BPAG2, laminin 332 (previously known as laminin 5 or epiligrin), hemidesmosome, lamina lucida	Linear basement membrane zone IgG and C3
Pemphigoid gestationis	Tense bullae, similar to bullous pemphigoid; onset during or immediately after pregnancy	Complement fixing, basement membrane zone, epidermal	BPAG2, BPAG1, hemidesmosome, lamina lucida	Linear basement membrane zone C3
Epidermolysis bullosa acquisita	Tense bullae; commonly occurs in areas of trauma and in oral mucosa	IgG basement membrane zone, dermal‡	Type VII collagen, anchoring fibrils	Linear basement membrane zone IgG and C3; may show linear IgA and IgM
Linear IgA bullous dermatosis and chronic bullous disease of childhood	Tense bullae, similar to bullous pemphigoid; oral involvement common in adult disease	IgA basement membrane zone, epidermal (rarely dermal)	97-kD portion of BPAG2, hemidesmosome, lamina lucida	Linear basement membrane zone IgA
Dermatitis herpetiformis	Small bullae on extensor surfaces (elbows and knees); markedly pruritic; associated with intestinal gluten sensitivity	IgA endomysial and transglutaminase antibodies; correlates with disease activity and compliance with gluten-free diet	Epidermal transglutaminase	Granular basement membrane zone IgA with stippling in dermal papillae
Bullous lupus erythematosus§	Tense bullae, photodistributed	IgG basement membrane zone, dermal	Type VII collagen, anchoring fibrils	Linear basement membrane zone IgG; may show granular IgM and C3 basement membrane zone as in lupus band

BPAG1, 230-kD bullous pemphigoid antigen 1; *BPAG2,* 180-kD bullous pemphigoid antigen 2; *C3,* complement component 3, *cell surface,* intercellular substance; *Ig,* immunoglobulin.
*In all suspected immunobullous disease, the biopsy for diagnosis should be obtained from perilesional tissue because immunoreactants may not be present in lesional tissue; perilesional skin is the area immediately adjacent to but not involving a lesion. Serum studies are also essential to differentiate diseases.
†The Nikolsky sign is the formation of a new blister or extension of a blister from shearing pressure applied on normal-appearing skin or at the edge of an existing blister.
‡*Dermal* and *epidermal* refer to localization of antibodies on human split skin by indirect immunofluorescence of serum.
From Adkinson NF et al: *Middleton's allergy principles and practice,* ed 8, Philadelphia, 2014, Saunders.

1. Light microscopy: Subepidermal bullae with eosinophils and/or neutrophils with associated eosinophil and/or neutrophil dermal infiltrate
2. Direct immunofluorescence (DIF) microscopy (gold standard): Linear IgG and or C3 deposits along dermoepidermal junction

- Immune serological tests. NOTE: Only confirmatory with DIF microscopy findings
  1. Indirect immunofluorescence (IIF): Circulating IgG anti-basement antibodies using 1 mol/L NaCl-separated normal skin as substrate
  2. ELISA: Test for anti-BP180 IgG; if negative, test for anti-BP230 IgG

Rx TREATMENT

Bullous pemphigoid may be a self-limited disease, but its course may last from months to yrs. Treatment is based on the degree of disease involvement and the rate of disease

progression; however, there is no general consensus on how to determine disease severity. A European guideline defines severity by percent skin involvement, with less than 10% defined as mild, between 10% and 30% defined as moderate, and greater than 30% defined as severe.

NONPHARMACOLOGIC THERAPY

- Mild soaps with emollients to wet skin after bathing
- Use of nonadherent dressings in the case of extensive erosive lesions to prevent bacterial superinfection, minimize pain, and promote healing
- Only drain larger blisters and leave the blister roof intact as a natural dressing; remove fluttering skin only in broken blisters
- Avoid mechanical trauma to the skin

STAGE-SPECIFIC THERAPY

- Mild: Topical class I steroids daily
- Moderate: Class I topical steroids daily; systemic therapy may be added as needed
- Severe: Class I topical steroids daily in combination with systemic immunosuppressants
- Intralesional triamcinolone acetonide to isolated lesions
- Oral antihistamines to control pruritus

TETRACYCLINES

- Doxycycline 100 mg twice daily is similar in effectiveness to oral prednisolone, with decreased side effects compared with oral steroids.
- Tetracycline 500 mg four times daily plus nicotinamide 500 mg three times daily had similar effectiveness as prednisone 40 to 80 mg daily.

SYSTEMIC STEROID INDUCTION THERAPY

- Prednisolone (or equivalent) 0.5 mg/kg per day, which can be combined with adjuvant immunosuppressive therapy, including azathioprine, dapsone, doxycycline, methotrexate, and mycophenolate mofetil
- Initial doses greater than 1.0 mg/kg of prednisolone show little added benefit

TREATMENT-RESISTANT THERAPY

- Intravenous immunoglobulin therapy 2 g/kg per cycle (4- to 6-week intervals)
- Immunoadsorption or plasmapheresis
- Rituximab (anti-CD20) 1000 mg IV on day 1 then day 14 *or* 375 mg/m^2 IV administered four times at weekly intervals

SYSTEMIC CONSOLIDATION THERAPY

- Once disease control is achieved with oral steroids, begin tapering corticosteroids by 25% at 7- to 14-day intervals; if induction dose is less than 20 mg/day, taper over 2- to 4-week intervals.
- If relapse occurs, return to dose given two reduction intervals prior; can resume taper after 14 days of disease control.
- May add or switch to adjuvant agents as needed.
- Disease control is defined as no new lesion formation concurrent with healing of existing lesions.
- Relapse is defined as greater than three new lesions per month or one lesion greater than 10 cm that does not heal spontaneously in one week or progression of the existing lesions or reemergence of daily pruritus.

DISPOSITION

In the United States, mortality rates are estimated at between 11% to 23% after 1 yr. Standardized mortality ratios range from 1.90 to 6.6. BP is a chronic disease; exacerbations and relapses are not uncommon, even in successfully treated individuals. A recent prospective study reported a 45% relapse rate of the evaluable patients at 12 months, with the majority of relapses occurring in the first 6 months after cessation of therapy. In this study, an ELISA titer score three times higher than the normal cutoff value at time of therapy cessation was the main predicting factor for BP relapse within the next yr. Dementia and initial extensive disease may be two additional independent risk factors associated with relapse during the first yr of therapy.

REFERRAL

Dermatology

PEARLS & CONSIDERATIONS

COMMENTS

- Pruritus can be the presenting complaint and can precede the appearance of any skin lesions.
- Bullous pemphigoid should be high on the differential in patients over 70 yr old with tense bullae.
- Extremely pruritic urticarial plaques can precede onset of tense bullae by months.
- Doxycycline 100 mg twice daily is equally effective to oral prednisolone.

BASIC INFORMATION

DEFINITION

- Delayed conduction in the His-Purkinje system that meets criteria for right bundle branch block (RBBB), left bundle branch block (LBBB), or hemifascicular block. The latter can be either left anterior fascicular block (LAFB) or left posterior fascicular block (LPFB). Bifascicular block is a combination of RBBB and either LAFB or LPFB. All of these are categories of bundle branch block. Any delayed conduction that does not meet these criteria is not considered bundle branch block but rather categorized as intraventricular conduction delay (IVCD) (see also topic "Intraventricular Conduction Delay"). Repolarization abnormalities may be seen in multiple leads with LBBB and in leads V1-V3 in RBBB. These include T wave inversions and ST segment depression in the opposite direction from the QRS complex. Fig. 1 illustrates a diagrammatic representation of fascicular blocks in the left ventricle. Table 1 and Table 2 summarize common diagnostic criteria for fascicular blocks and bundle branch blocks.
- The bundle branch block can be persistent or intermittent. The latter is predominantly rate-related, usually RBBB, during tachycardia or acute shortening of the R-R interval, which is common during atrial fibrillation. Bradycardia-dependent aberrancy can also be seen. Alternating bundle branch block between RBBB and LBBB is a sign of conduction system disease and will often progress to complete heart block.

SYNONYMS

- Fascicular block
- Aberrancy
- Conduction disturbance
- Conduction delay
- Conduction defect

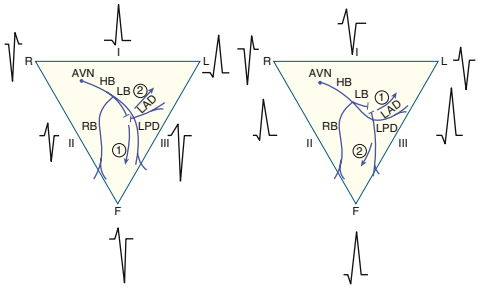

FIG. 1 Diagrammatic representation of fascicular blocks in the left ventricle. *Left,* Interruption of the left anterior fascicle or division (here labeled LAD) results in an initial inferior (1) followed by a dominant superior (2) direction of activation. *Right,* Interruption of the left posterior fascicle or division (here labeled LPD) results in an initial superior (1) followed by a dominant inferior (2) direction of activation. *AVN,* Atrioventricular node; *HB,* His bundle; *LB,* left bundle; *RB,* right bundle. TABLE 1 Common Diagnostic Criteria for Fascicular Blocks

Left Anterior Fascicular Block

Frontal plane mean QRS axis between −45 and −90 degrees qR pattern in lead aVLQRS duration <120 msec
Time to peak R wave in aVL ≥45 msec

Left Posterior Fascicular Block

Frontal plane mean QRS axis between +90 and +180 degrees rS pattern in leads I and aVL with qR patterns in leads III and aVF
QRS duration <120 msec
Exclusion of other factors causing right axis deviation (e.g., right ventricular overload patterns, lateral infarction)

aVF, Augmented vector foot; *aVL,* augmented vector left.
From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

TABLE 2 Common Diagnostic Criteria for Bundle Branch Blocks

Complete Left Bundle Branch Block

QRS duration ≥120 msec
Broad, notched, or slurred R waves in leads I, aVL, V5, and V6
Small or absent initial r waves in right precordial leads (V1 and V2) followed by deep S waves
Absent septal q waves in leads I, V5, and V6
Prolonged time to peak R wave (>60 msec) in V5 and V6

Complete Right Bundle Branch Block

QRS duration ≥120 msec rsr′, rsR′, or rSR′, patterns in leads V1 and V2
S waves in leads I and V6 ≥40 msec wide
Normal time to peak R wave in leads V5 and V6 but >50 msec in V1

aVF, Augmented vector foot; *aVL,* augmented vector left.
From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

ICD-10CM CODES
Bundle branch block (fascicular block):
I44.4 Anterior
I44.5 Posterior
I44.60 Hemiblock (hemifascicular block)
I44.7 Left
I45.10 Right
I45.2 Bilateral (bifascicular)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The cumulative incidence of any type of bundle branch block increases with age (1.5% at age 50, 18% at age 80)
PEAK INCIDENCE: Cumulative incidence of 18% at age 80 for any type of bundle branch block
PREVALENCE: The estimated prevalence in the general population for any type of bundle branch block ranges between 0.2% and 3.4% and increases with age.

- Complete LBBB: 0.4% men age 50, 5.7% men age 80, 1.1% women age 50 to 80
- Complete RBBB: 0.2% men before age 30, 0.8% men age 50, 1.3% men age 80, 1.3% women age 50 to 80, 2.3% in men and women age 60
- Incomplete RBBB: 13.5% age 20, 3.4% age 50

PREDOMINANT SEX AND AGE: More common in men, incidence increases with age
GENETICS: Most cases of bundle branch block are not hereditary. The Brugada syndrome is an autosomal dominant genetic disorder with pseudo-RBBB but is not a true bundle branch block (see section on Brugada Syndrome). The hereditary bundle branch defect is an autosomal dominant genetic disease that has been described in Lebanon and was mapped to the long arm of chromosome 19.
RISK FACTORS: Male gender, elder age, structural heart disease, cardiomyopathy, hypertension

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- RBBB can cause wide splitting of the second heart sound (S_2). Either LBBB or RBBB can cause continuous splitting of S_2 during respiration.
- Isolated bundle branch block does not cause symptoms. Nevertheless, it is usually a result of heart disease, either in the conduction system or the surrounding cardiac tissues, and its existence can aggravate the clinical picture of the causal entity.
- In patients with heart failure, the presence of LBBB can cause ventricular dyssynchrony and worsen heart failure. LBBB or RBBB, when coexistent with coronary artery disease, diabetes, or heart failure, are markers for increased mortality.
- RBBB can be seen in pulmonary hypertension or acute pulmonary embolism, generally in entities that increase the right ventricular afterload. The presence of bundle branch block can be associated with other conduction defects such as second or third degree AV block.

Bundle Branch Block

ETIOLOGY

- Bundle branch block can be a result of disease in the His-Purkinje conduction system but can also result from disease or fibrosis surrounding the conduction system (i.e., myocardial infarction), antiarrhythmic drugs, or hyperkalemia. Selected causes of bundle branch block are the following: intracardiac catheter manipulation, myocardial ischemia or infarction, myocarditis, cardiomyopathy, and Lenegre or Lev disease. RBBB in particular is associated with pulmonary hypertension and pulmonary embolism, whereas LBBB can be caused by an anterior myocardial infarction.
- Rate-related branch block in normal hearts is usually seen in tachycardia or in atrial fibrillation where a long R-R interval is followed by a shorter one. This is due to Ashman phenomenon, where a long cycle length interval causes prolongation in the refractory period resulting in bundle branch block on the subsequent early beat. This is a common property of all cardiac tissues but more evident in the conduction system. The rate-related bundle block is usually RBBB since the right bundle has a longer refractory period than the left bundle for the same heart rate. Another phenomenon is bradycardia-dependent aberrancy. This may be due to automaticity in a bundle branch block during diastole leading to BBB on a subsequent beat. Other explanations include vagal tone inhibition or phase 4 block. In phase 4 block, the cells have depleted sodium reserves resulting in low resting membrane potentials that impose difficulty in cell excitability resulting in conduction block.
- In patients with LBBB, detailed mapping has demonstrated that the site of block is in the proximal left conduction system in 64% of cases.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Refer to Table 3.
- An accessory pathway can cause an appearance of RBBB or LBBB. If lead V1 is placed higher than the fourth intercostal space or more right than the parasternal area, the EKG can resemble incomplete RBBB.
- An inferior myocardial infarction can resemble left anterior fascicular block, but in the inferior myocardial infarction, the inferior leads (II, III, aVF) will have qR instead of QS morphology. Left posterior fascicular block can resemble lateral myocardial infarction, right ventricular hypertrophy, dextrocardia, or lateral accessory pathway. Accelerated idioventricular rhythm can resemble LBBB or RBBB, depending on the origin of the ventricular pacemaker site.

WORKUP

- Resting, ambulatory, and exercise electrocardiogram
- Investigation of coexistent comorbidities such as heart failure, myocardial infarction, and cardiomyopathies
- Acute LBBB should prompt investigation for anterior myocardial infarction (Fig. 2) whereas acute RBBB for pulmonary hypertension, or pulmonary embolism (Fig. 3)
- Figs. 2 and 3 illustrate diagnostic evaluations for bundle branch block.

LABORATORY TESTS

- Standard laboratory testing appropriate for age, gender, and metabolic abnormalities
- Electrolyte abnormalities and especially hyperkalemia should be excluded

IMAGING STUDIES

Electrocardiogram (Figs. 4 and 5)

Rx TREATMENT

- Treat the underlying cause (Tables 4 and 5)
- In asymptomatic patients with an isolated bundle branch block, no therapy is required

NONPHARMACOLOGIC THERAPY

Cardiac resynchronization therapy (CRT) with biventricular or His-bundle devices can benefit selected patients with LBBB and depressed EF, if heart failure is present. Permanent pacemaker is appropriate for patients with cardiac syncope or coexisting third degree, or Mobitz type II second degree AV block, when not due to a reversible cause.

ACUTE GENERAL Rx

In acutely established bundle branch block, investigate the cause. In acute LBBB, anterior myocardial infarction should be investigated whereas in acute RBBB investigation should target pulmonary embolism.

CHRONIC Rx

Optimization of potential coexisting comorbidities such as coronary artery disease, heart failure, hyperkalemia, diabetes

DISPOSITION

There is no specific disposition plan for isolated bundle branch block. Entities such as myocardial ischemia or infarction, myocarditis, and cardiomyopathy should be investigated prior to disposition in a new bundle branch block with associated symptoms. Pulmonary embolism should also be investigated in a new RBBB with suspecting symptoms.

REFERRAL

In selected patients at risk for sudden cardiac death such as Brugada syndrome, or in cases of new bundle branch block associated with acute symptoms, referral is indicated.

! PEARLS & CONSIDERATIONS

COMMENTS

Acute LBBB can be caused by anterior myocardial infarction. Acute RBBB can be due to pulmonary embolism. Bundle branch block is a normal variant, especially in young individuals. History and physical exam are needed to identify associated cardiac abnormalities. In patients with heart failure, and depressed ejection fraction, cardiac resynchronization is beneficial in the presence of LBBB but not in the presence of RBBB.

TABLE 3 Differential Diagnosis of Bundle Branch Block

	Right Bundle Branch Block		Left Bundle Branch Block		Hemifascicular Block	
	Incomplete	**Complete**	**Incomplete**	**Complete**	**Left Anterior Fascicular Block**	**Left Posterior Fascicular Block**
QRS Axis	Normal	Normal	Normal or left	Normal or left	Left and >–45°	Right and >+90°
QRS Duration	<120 msec	>120 msec	<120 msec	>130 msec	<120 msec	<120 msec
I	qRs	Deep S	No q wave	Tall R wave, no q wave, no S wave	Positive QRS	rS
aVL	qRs	Deep S		Tall R wave, no q wave, no S wave	qR	rS
II, III, aVF					rS	qR
Precordial Leads	rSR' in V1-V2, qRs in V5-V6	RsR' in V1-V2, deep S in V5-V6	No q wave in V5-V6	QS or rS in V1-V2, tall R wave and no q wave or S wave in V5-V6	Poor R wave progression in V1-V3	
aVR	rsR'				Often tall R wave	

aVF, Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right.

(From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

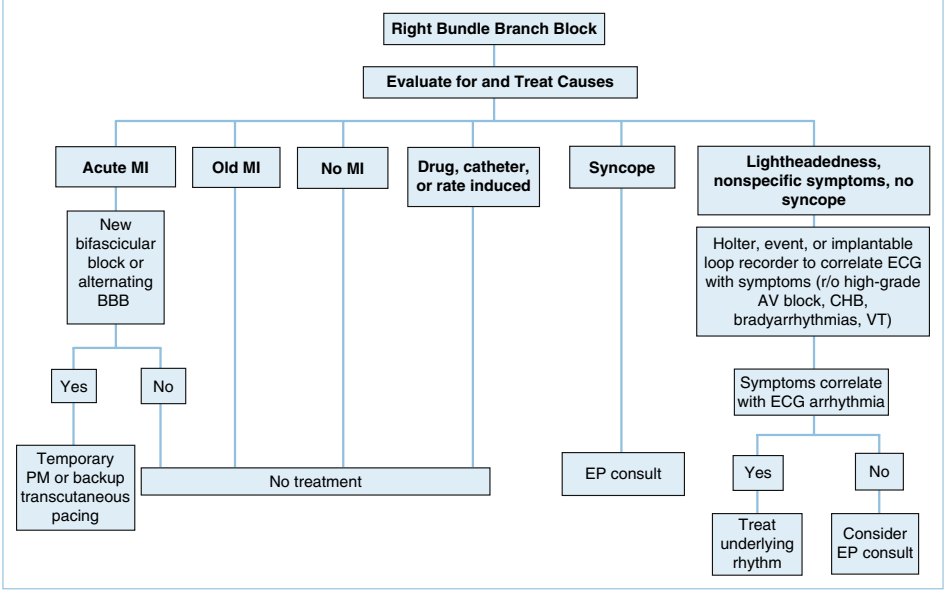

FIG. 3 Right bundle branch block. *AV,* Atrioventricular; *BBB,* bundle branch block; *CHB,* complete heart block; *ECG,* electrocardiogram; *EP,* electrophysiology; *MI,* myocardial infarction; *PM,* pacemaker; *VT,* ventricular tachycardia. (From Olshansky B,et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

PREVENTION

Modification of associated comorbidities such as optimization of heart failure, coronary artery disease, hypertension, and diabetes.

PATIENT & FAMILY EDUCATION

Bundle branch block is a problem in the heart's electrical system. There are several types, but clinically the most important is the left bundle branch block in which one of the two main "wires" in the heart is not functioning correctly. As a result, the heart's pumping chambers are squeezing out of sync and can worsen the heart's ability to pump in people with heart failure. It is more common in older adults and people with serious heart disease.

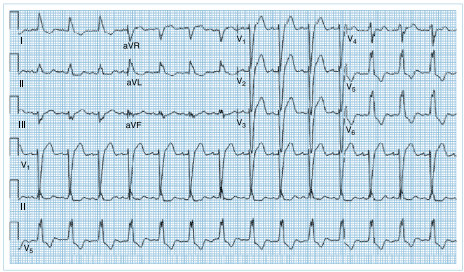

FIG. 4 Left bundle branch block. This 12-lead electrocardiogram shows LBBB that is characterized by a wide (>0.12 seconds) QRS complex; broad monophasic R waves in leads V5, V6, and I that are commonly slurred or notched; rS or QS complexes in the right precordial leads; and secondary ST- and T-wave changes that are opposite in direction to the major QRS deflections. The mean frontal plane QRS axis is normal, but left-axis deviation may be present. aVF, Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right; *LBBB,* left bundle branch block. (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

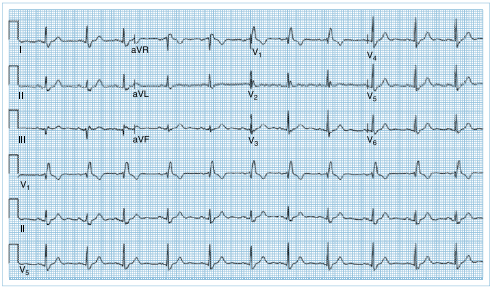

FIG. 5 Right bundle branch block. This 12-lead electrocardiogram shows RBBB that is characterized by a wide (≥0.12 seconds) QRS complex; a secondary R wave (R′) in V1 and V2 (rsR′ or rSR′) with R′ usually taller than the initial R wave; a wide, slurred S wave in leads V5, V6, and I; and secondary ST- and T-wave changes that are opposite in direction to the terminal QRS deflections over the right precordial leads. The mean frontal plane QRS axis is normal. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right; *RBBB,* right bundle branch block. (From Olshansky B et al: *Arrhythmia essentials,* ed 2, Philadelphia, 2017, Elsevier.)

TABLE 4 Left Bundle Branch Block Management

Setting	Therapy
Asymptomatic normal LV function	• No therapy—rule out structural heart disease, ischemic heart disease. • Requires long-term follow-up. • If instrumentation of the right ventricle is planned, be ready to temporarily pace (preferably externally or via a temporary pacemaker wire) if transient traumatic RBBB with resultant complete AVB is induced. • Trauma to the right bundle can last from minutes to more than 24 hours.
Symptomatic (syncope, lightheadedness)	• Admit, monitor, and evaluate for structural heart disease. • If syncope occurs, EP consultation and possible EP testing is indicated. • If HV interval is 100 msec or more or if infra-Hisian block is provoked with atrial pacing at rates of <160 bpm with or without procainamide challenge, implant a permanent pacemaker.
Symptomatic cardiomyopathy (CHF)	• If LVEF is 35% or less, NYHA class II, III, or IV heart failure symptoms are present with LBBB with QRS duration of more than 130 ms: CRT-D ICD implantation is indicated (may improve LV function, reduce heart failure symptoms, and reduce the risk of sudden death).
Myocardial infarction	• New (or not known to be old) LBBB: revascularization with direct PTCA with or without stent. • Temporary pacemaker if second-degree or third-degree AVB is present. • New onset LBBB indicates extensive myocardial ischemia or infarction and is associated with worse prognosis. • Have external (transcutaneous) pacing on standby if no AVB is present.
Preoperative	• No therapy is required if the patient is asymptomatic, whether or not coronary artery disease or systolic dysfunction is present. • Cardiac workup (stress test, echocardiogram) to exclude structural heart disease if symptomatic. • LBBB is not per se an indication for treadmill testing. If stress testing is performed, imaging must accompany the test if the aim is to document the presence of obstructive coronary artery disease; imaging is not required if the aim of the stress test is the assessment of effort tolerance.
Postoperative	• No therapy if asymptomatic. • Common after aortic valve replacement (usually persistent) and after CABG (transient due to cardioplegia).
Alternating LBBB and RBBB	• Alternating BBB may be due to trifascicular disease • Because of the high rate of progression to CHB, permanent pacemaker implantation is advised. • Alternating BBB may also be seen as a digitalis toxic rhythm, although in current practice this occurs only rarely.

AVB, Atrioventricular block; *BBB,* bundle branch block; *CABG,* coronary artery bypass graft; *CHB,* complete atrioventricular block; *CHF,* congestive heart failure; *CRT-D,* cardiac resynchronization and defibrillation therapy; *EP,* electrophysiology; *HV,* histoventricular; *ICD,* implantable cardioverter defibrillator; *LBBB,* left bundle branch block; *LV,* left ventricular; *LVEF,* left ventricular ejection fraction; *NYHA,* New York Heart Association; *PTCA,* percutaneous transluminal coronary angioplasty; *RBBB,* right bundle branch block.

TABLE 5 Right Bundle Branch Block Management

Setting	Therapy
Outpatient asymptomatic	• No therapy. • May occur with instrumentation of the right ventricle (e.g., Swan-Ganz catheter) and trauma to the right bundle. • Can last up to 24 h.
Symptomatic (syncope)	• Admit the patient with RBBB who has syncope. • If symptoms of syncope occur (may be related to AVB or VT), attempt to correlate symptoms with rhythm by Holter or event monitoring. • Evaluate for underlying structural cardiac disease. • Consider EP testing to assess AV conduction and the presence of inducible VT (present in up to 30% of symptomatic RBBB patients) if the patient is syncopal.
MI	• Isolated RBBB: No therapy. • RBBB with LAFB or LPFB (that is new or not known to be old) or alternating BBB: • Temporary pacemaker • Alternatively, placement of a transcutaneous pacing system • RBBB occurs in 3%-7% of MIs, often with LAFB, and usually because of anterior or anteroseptal infarction. • The combination is less common in the current era of early revascularization via percutaneous techniques.
Preoperative	• No therapy—temporary pacemaker not required. • Perform cardiac evaluation to exclude other cardiovascular disease.
Postoperative	• No treatment. • Most common conduction disturbance in this setting.
Alternating LBBB and RBBB	• Permanent pacemaker if not due to reversible cause.

AV, Atrioventricular; *AVB,* atrioventricular block; *BBB,* bundle branch block; *EP,* electrophysiology; *LAFB,* left anterior fascicular block; *LBBB,* left bundle branch block; *LPFB,* left posterior fascicular block; *MI,* myocardial infarction; *RBBB,* right bundle branch block; *VT,* ventricular tachycardia.

Burning Mouth Syndrome

BASIC INFORMATION

DEFINITION

Burning mouth syndrome (BMS) is an uncommon disorder characterized by continuous burning pain in the tongue or oral mucous membranes where no underlying dental or medical cause can be identified and no oral signs are found. BMS may be accompanied by subjective xerostomia (dry mouth sensation in which no cause can be found), dysgeusia (altered taste), dysosmia (altered smell), and oral paresthesia (e.g., tingling).

Diagnostic criteria:

- Oral pain fulfilling criteria B and C
- Recurring daily for >2 hours per day for >3 months
- Pain has both of the following characteristics:
  1. Burning quality
  2. Felt superficially in the oral mucosa
- Oral mucosa is of normal appearance, and clinical examination including sensory testing is normal.
- Not better accounted for by another ICHD-3 (the *International Classification of Headache Disorders, 3rd edition*) diagnosis

SYNONYMS

BMS
Glossodynia
Oral dysesthesia
Glossopyrosis
Stomatodynia

ICD-10CM CODE
K14.6 Glossodynia

EPIDEMIOLOGY & DEMOGRAPHICS

- 5 per 100,000 general population.
- Women 3 to 7 times more likely than men of a similar age; most prevalent in postmenopausal women.
- Typically occurs in middle-aged or older adults. The prevalence may increase from three- to twelvefold with increasing age.
- Asian and Native Americans have considerably higher risk.
- 30% to 50% of patients improve spontaneously.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Sensation is usually bilaterally located on the tongue, most frequently on the anterior two thirds of the tongue, the anterior hard palate, and the lower lip mucosa.
- Sensation most typically described as burning, scalded, or tingling. Sometimes described as "discomfort," "tender," or "annoying" rather than pain or burning.
- The oropharyngeal exam may show atrophy, erythema, leukoplakia, erosion, or ulceration.
- May present with oral parafunctional habits such as bruxism, jaw clenching, and tongue thrusting, which are increased with anxiety.
- Pain is chronic and often lasts at least 4 to 6 months.
- Up to two thirds of patients report a spontaneous partial recovery within 6 to 7 yr from onset, with the pain changing from constant to intermittent.

ETIOLOGY

More than 50% of cases have no identifiable cause (primary BMS). Many of the currently proposed etiologies of secondary BMS include:

- Psychological dysfunction: Many patients concomitantly have personality or mood changes, report more adverse life events, somatization, anxiety, and depression. A proportion of patients have anxiety centered around concerns of cancer (cancerphobia).
- Neurologic: Decreased levels of dopamine likely contribute to the painful clinical conditions, including burning mouth syndrome.
- Endocrine: Hormonal alterations, especially in menopause, lead to a deficit in neuroprotective steroids that can cause atrophic changes in oral mucosa.
- Immunologic: Observational studies have shown elevation of serum erythrocyte sedimentation (ESR) rate and salivary immunoglobulin A compared with control patients.
- Infectious: Fusospirochetes, *Candida, Enterobacter, Helicobacter pylori,* and *Klebsiella* infection. *Candida* may not always produce visible lesions.
- Local irritants, such as smoking, and dental materials, such as mercury.
- Medications, such as angiotensin-converting enzyme (ACE) inhibitors and protease inhibitors.
- Trigeminal small-fiber sensory neuropathy.
- Nutritional deficiencies: Iron, zinc, folate, and vitamin B.

There may be an association between supertasters (those with enhanced ability to taste) and those with BMS caused by their increased density of taste buds that are surrounded by bundles of trigeminal nerve neurons.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mucosal disease such as lichen planus, candidiasis, xerostomia, pemphigoid, and allergic contact stomatitis
- Nutritional deficiency in zinc, iron, folate, or vitamins B_1, B_2, B_6, B_9, B_{12}
- Dry mouth from Sjögren syndrome or after chemo/radiation therapy
- Cranial nerve injury
- Medication effect
- Systemic factors such as diabetes, abnormal thyroid, autoimmune conditions, Parkinson disease

WORKUP

- Clinical history is the most important in diagnosing BMS.
- Very important to rule out other pathologic conditions first.

LABORATORY TESTS

There is no diagnostic test for BMS but consider testing for vitamin B, folate, ferritin, or zinc deficiency as well as CBC, luteinizing hormone, follicle-stimulating hormone, hemoglobin A1c, thyroid function (T_3/T_4), and ESR.

TREATMENT

NONPHARMACOLOGIC THERAPY

Consider discontinuation of medications that may cause xerostomia (e.g., anticholinergics, psychotropics) and substitution for medications that may cause oral burning (e.g., ACE inhibitors, angiotensin-receptor blockers, antiretrovirals). Formal psychotherapy and cognitive behavioral therapy have been helpful for some patients.

- Capsaicin (hot pepper powder) can be used as a topical desensitizing agent.
- Rinse mouth with 1 tsp of a 1:2 solution of hot pepper and water; increase strength of capsaicin as tolerated to a maximum 1:1 dilution.

ACUTE GENERAL Rx

No definitive cure exists. Attempting combinations of therapies may be appropriate. Interestingly, cognitive therapy may be synergistic with other agents.

Treatment options currently include:

- Low-dose benzodiazepines:
  1. Clonazepam 0.25 to 2 mg/day; start with 0.25 mg at bedtime and increase dose q4 to 7 days until oral burning is relieved or side effects.
  2. Topical clonazepam solution 0.1 to 0.5 mg/ml; swish with 5 ml for 5 minutes and spit two to four times daily.2.
- Low-dose tricyclic antidepressants:
  1. Amitriptyline or nortriptyline 10 to 150 mg/day; start with 10 mg at bedtime and increase dose by 10 mg q 4 to 7 days.
- Low-dose gabapentin 300 to 1600 mg/day; start with 100 mg at bedtime and increase dose by 100 mg q 4 to 7 days (take in divided doses).
  1. Oral nystatin
- Capsaicin (topical oral) dopaminergic D2 agonists: Pramipexole
  1. Based on the dopaminergic dysfunction in BMS, a case report described the use of pramipexole 0.125 mg at night with improvement with symptoms in 4 weeks. A case series of 6 patients with BMS also demonstrated clear improvement of symptoms in all cases with the doses between 0.36 mg and 1.05 mg per day.
- Low-level laser therapy:
  1. Clinical trials have shown improved symptom control when given over two sessions weekly for 4 to 5 wk and can be an alternative treatment to psychoactive drugs.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Antioxidant alpha lipoic acid
- Acupuncture may be effective
- Relaxation programs and massage

REFERRAL

Consider referral to a subspecialist in this area, such as a dentist or ENT if initial therapy fails to resolve symptoms. Surgery is not recommended.

PEARLS & CONSIDERATIONS

COMMENTS

BMS is a rare but possibly debilitating disease that can be highly frustrating to the patient and the practitioner. The patient often experiences an unremitting burning pain in the mouth without any apparent clinical signs, and the practitioner is unable to definitively diagnose symptoms even with the use of laboratory testing or imaging. Other diseases should be ruled out.

BASIC INFORMATION

DEFINITION

- Cutaneous burns can be classified by type of injury (e.g., thermal vs. chemical), burn depth (e.g., first, second, third degree), extent of burn (total burn surface area [TBSA]), and burn severity (e.g., minor vs. major). Types of burn injury include thermal (flames, scalds, hot contactants), chemical, electrical, and radiation burns. This chapter will focus on thermal and electrical burns.
- Burns can affect skin and respiratory, ocular, oral, and genital mucosa.

SYNONYMS

Thermal injury
Chemical injury
Electrical injury
Radiation injury

ICD-10CM CODES

T29.0 Burns of multiple regions, unspecified degree
T30.0 Burn of unspecified body region, unspecified degree
T30.1 Burn of first degree, body region unspecified
T30.2 Burn of second degree, body region unspecified
T30.3 Burn of third degree, body region unspecified
T31.0 Burns involving less than 10% of body surface
T31.1 Burns involving 10%-19% of body surface
T31.2 Burns involving 20%-29% of body surface
T31.3 Burns involving 30%-39% of body surface
T31.4 Burns involving 40%-49% of body surface
T31.5 Burns involving 50%-59% of body surface

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.):

- More than 1.2 million individuals experience burns in the U.S., and burn injuries account for approximately 500,000 emergency department visits, with 9% (45,000) requiring hospitalization and 0.8% (4000) resulting in death annually.
- Of thermal injury, scald burn from liquid is most common—followed by flame, flash burn, and then contact burn.

PREDOMINANT AGE & SEX: Children ages 2 to 4 yr have the greatest frequency of burns (most commonly scald burns), with male adolescent and young adults ages 17 to 25 with second greatest frequency (most commonly from flammable liquids).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- It is important to note that burns occur unevenly, often with various depths (Table 1)
- First-degree (superficial) burns: penetrate epidermis only (minimal barrier loss)
  1. Very painful, intact, erythematous skin with minimal to no edema and no blistering
- Second-degree (partial-thickness) burns: epidermis and part of dermis is affected
  1. Moist, very painful skin with edema and blistering/blebs
  2. Superficial partial-thickness burns: cherry red with two-point discrimination intact, incredibly painful
  3. Deep partial-thickness burns: mottled white and cherry red; only the sensation of pressure is intact in these areas
- Third-degree (full-thickness) burns: entire epidermis and dermis are affected, with destruction of hair follicles and sweat glands
  1. The skin is dry, charred, pale, painless, and leathery; charred vessels may be visible beneath, little or no pain, and hair pulls out easily

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cultural practices leading to burnlike lesions in distinctive patterns (e.g., cupping, coining, moxibustion), cellulitis, Stevens-Johnson syndrome/toxic epidermolytic necrolysis

CLASSIFICATION

- Burns are classified by (1) depth of injury, (2) extent of injury, and (3) severity, according to the American Burn Association.
- Depth of injury (see Table 1):
  1. Indicates how the wound will heal and whether grafting will be needed.
- Extent of TBSA:
  1. The TBSA is best classified by using age-specific burn charts and the "rule of nines" (Fig. 1).
  2. For scattered burns, utilizing patient's palm including fingers to equate 1% body surface area can be helpful.
  3. TBSA indicates how aggressively the patient will need to be resuscitated.
- Severity: Determined by burn depth, TBSA, age, location, type of injury, and presence/absence of coexisting conditions. Severity classification helps triage patients to outpatient, inpatient, or burn unit care (see Table 2).
  1. Minor burns: outpatient management
  2. Moderate burns: admission to hospital with experience managing burns or burn center referral
  3. Major burns: referral to burn center

LABORATORY STUDIES (MODERATE OR MAJOR BURNS)

- CBC, electrolytes, BUN, creatinine, glucose, liver function tests, venous blood gas, blood coagulation, and type and screen in anticipation of blood transfusion
- *If smoke inhalation expected:* Serial ABG carboxyhemoglobin and continuous ECG
- *If electrical burn or if concern for rhabdomyolysis:* Urinalysis, urine myoglobin, and CPK levels

TABLE 1 Categorization of Burn by Depth

Burn Type	Histologic Depth	Clinical Presentation	Treatment	Healing Time/Prognosis
1st degree	Epidermis	Erythematous but intact skin, no blisters, pain may range in severity	Topical salves, cold compresses, NSAIDs for pain control	2-5 days with no scarring
Superficial 2nd degree (partial thickness)	Papillary dermis	Erythematous with superficial blisters, intense pain	Topical antimicrobials with gauze dressing or biosynthetic dressing (if widespread), pain control	5-21 days with no grafting
Deep 2nd degree (partial thickness)	Reticular dermis	Erythematous with superficial/deep blisters, range of pain depending on nerve involvement	Same	21-35 days with no infection; if infected, converts to full-thickness burn
3rd degree (full thickness)	Through dermis to subcutaneous tissue. Can involve fascia, muscle, and bone.	White or black, possible eschar, may or may not be painful depending on nerve damage	Usually requires grafting, may require resuscitation depending on TBSA affected, pain control	Large areas require grafting, but small areas may heal from the edges after wks

NSAID, Nonsteroidal antiinflammatory drug; *TBSA,* total body surface area.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders; and Kessides MC, Skelsey MK: Management of acute partial-thickness burns, *Cutis* 86:249-257, 2010.

- *If severe lactic acidosis:* Consider checking cyanide level

IMAGING STUDIES

- If smoke inhalation suspected: Chest radiograph and bronchoscopy
- If high-voltage electrical burn: Cardiac monitoring first 24 hours

Rx TREATMENT

ACUTE GENERAL Rx

MINOR BURNS (FIRST-DEGREE BURNS AND SECOND/THIRD-DEGREE BURNS OF LIMITED TBSA):

- Outpatient management: "6 Cs"
  1. Clothing: Remove hot or burned clothing.
  2. Cooling: Cool (approximately 54° F [12.22° C]) for 10 to 30 min (under faucet or compress) to reduce edema/pain by conducting heat away from skin. Not recommended with extensive burns due to theoretical risk of hypothermia and shock. No ice packs.
  3. Cleaning: Wash gently with mild alcohol-free soap, then normal saline daily. Remove all old ointment and any loose skin. Blot dry. No evidence supports vigorous cleansing with antiseptic solutions. Embedded materials should be removed by copious irrigation using a large-gauge syringe.
  4. Chemoprophylaxis: Tetanus immunization (all deep second- and third-degree burns). Routine skin cultures are NOT recommended except when wound infection suspected, and prophylactic systemic antibiotics are NOT recommended. All second- and third-degree burns are treated with a topical antimicrobial agent. This may include silver sulfadiazine, bacitracin, bismuth-impregnated Vaseline gauze, or silver-impregnated synthetic dressings.
  5. Covering: All second- and third-degree burns should be covered with sterile dressing. If financial resources are limited, instead of gauze, can purchase cotton gloves, T-shirts, or similar at discount stores, wash, and reuse.
  6. Comfort: Analgesics (Tylenol and NSAIDs—alone or in combination with opioids) around the clock are recommended. Additional "rescue" analgesics before dressing changes and physical activity recommended.

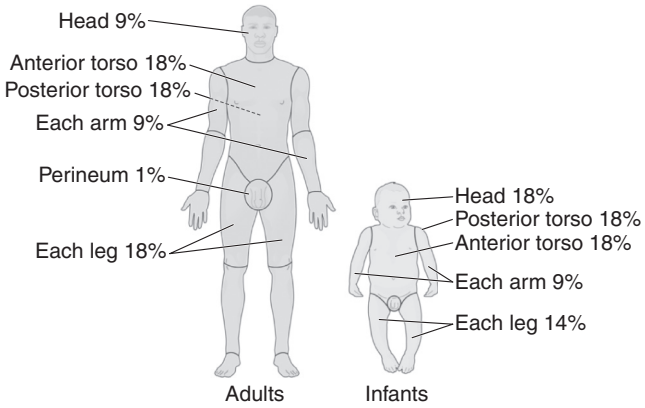

FIG. 1 The "rule of nines" for estimating second-degree and third-degree burns. Because infants have significantly larger heads and smaller legs than do adults, different rules must be used in evaluating these patients. A simple, practical rule is that the palm of the patient's hand, with fingers, equals 1% of the total body area. (From Ferri F: *Practical guide to the care of the medical patient,* ed 9, St Louis, 2014, Elsevier.)

MODERATE AND MAJOR BURNS (SECOND/THIRD-DEGREE BURNS OF EXTENSIVE TBSA):

- Patients with moderate/major burns (Fig. 1) should be admitted to the hospital or referred to a burn center. Indications for hospitalization for burns are described in Table 2. Burn care can be compartmentalized into four main phases: initial assessment and triage (phase I), resuscitation (phase II), burn wound coverage and critical care (phase III), and rehabilitation (phase IV) (Fig. 2).
  1. Assessment of ABCs: Establish airway and assess breathing (inspect for inhalation injury and intubate for suspected airway edema, often seen 12 to 24 hours later); O_2; establish circulation (place two large-bore peripheral IV lines, ECG).
  2. IV fluid resuscitation: Various fluid resuscitation formulas have been proposed and used to guide burn providers. These formulas each estimate the amount each patient may require during the course of a 24- to 48-hour postburn resuscitation period. The goal is to maintain optimal end-organ perfusion during this time with volume replacement at the lowest physiologic cost. Parkland formula (Ringer lactate at 2 to 4 ml/kg per % TBSA per 24 hours with half the calculated fluid given in the first 8 hours) is an effective modality in severe burns (Fig. 3) and has been commonly used. Once fluid resuscitation is initiated, the crystalloid rate should be titrated up or down on a regular basis while maintaining a urine output of around 0.5 to 1.0 ml/kg/h in adults. Various algorithms and clinical protocols have been proposed. One such algorithm is depicted in Fig. 4. The goal of burn resuscitation is to provide adequate fluid necessary to avoid end-organ failure while avoiding "fluid creep." Rescue therapy in the form of colloid infusion with albumin has been described as "colloid rescue." The military's Joint Trauma System Clinical Practice Guidelines recommend that 5%

TABLE 2 Classification of Burns by Severity and Indications for Hospitalization or Burn Center Referral

Criteria	Minor Burn	Moderate Burn	Major Burn
Total body surface area (%)	All 1st degree burns <10% adults <5% children or elderly <2% for 3rd degree	2nd degree burns 10%-20% adults 5%-10% in children or elderly 2%-5% 3rd degree	All 1st degree burns >20% adults >10% children and elderly >5% 3rd degree
Type of burn injury		Low-voltage burn Suspected inhalation injury	High-voltage burn Chemical burn Known
Location		Circumferential burn	Clinically significant burn to face, eyes, ears, genitalia, over joints
Coexisting conditions		Concomitant medical problem predisposing to infection (e.g., diabetes, sickle cell anemia)	Significant associated injuries (e.g., fracture, other major trauma)
	Outpatient management	Inpatient management—consider referral to burn center*	Referral to burn center

*Per the American Burn Association (ABA), any partial-thickness burn >10% total body surface area or any factors listed in moderate or major burn category warrant referral to burn center. Additional factors per the ABA include burned children in a hospital without qualified personnel or equipment for the care of children and burn injury in a patient who will require special social, emotional, or rehabilitative intervention (including suspected child abuse).

Modified from Singer AJ, Dagum AB: Current management of acute cutaneous wounds, *N Engl J Med* 359 (10):1037-1046, 2008.

albumin should be initiated as early as 8 hours after a burn if certain conditions are met. These conditions include that the hourly IV fluid rate exceeds 1500 ml/h or the projected 24-hour total fluid volume approaches 250 ml/kg.

3. Baseline neurologic and vascular assessment.
4. Foley catheter and NG tube (20% of patients develop an ileus): Urine output 30 ml/h.
5. Optimize nutritional support: Mayes equations to calculate energy requirements after burn (Box 1).

- Frequent reassessment in the first 24 to 72 hours, as wound depth can change significantly.

Phase I

Initial Assessment and Triage

- Stop the burning process. Remove patient and providers from harm.
- **Primary Survey**
  - **Airway**—Assess for ability to maintain patent
  - **Breathing**—Evaluate for inhalation injury/carbon monoxide
  - **Circulation**—Evaluate adequacy of perfusion
- **Begin Resuscitation**
  - Secure intravenous or intraosseous access and begin judicious fluids (lactated Ringer)
- **Secondary Survey**
  - Evaluate for other traumatic injuries
  - Use Rule of 9's for TBSA estimate, and Rule of 10's to calculate initial fluid rate

Phase II

Fluid Resuscitation: 0–48 h

- Titrate IV rate hourly based on a compilation of various endpoints centered on urine output
  - Urine output goal—30–50 mL/h (or approximately 0.5 mL/kg per hour)
  - Use other endpoints to guide resuscitation (lactate, base deficit, $ScvO_2$, CVP, MAP, etc.)
- Albumin early for "runaway" resuscitation. Consider other adjuncts such as plasma, high-dose vitamin C, and plasmapheresis
- Serial evaluation for resuscitation morbidity
  - Abdominal compartment syndrome, extremity compartment syndrome, pulmonary edema, cerebral edema

Phase III

Burn Wound Coverage and Critical Care—Continue Until Definitive Coverage Has Been Attained

- Surgical debridement (if indicated) via burn wound excision and autografting (definitive coverage)
  - Temporary coverage with skin substitutes if inadequate availability of autograft
- Optimize conditions for wound healing—Optimize hemodynamics, organ support, nutrition support
- Prevent and treat infectious complications (wounds, blood, lung, bladder, etc.)
- Prevent hospital complications (DVT, stress ulcers, decubitus)

Phase IV

Rehabilitation/Resilience—Begin Early and Continue Through Discharge and Beyond

- Proper limb positioning to prevent contractures
- Aggressive rehabilitation—Active range of motion, exercise
- Anabolic agents (propranolol, oxandrolone)
- Psychosocial support

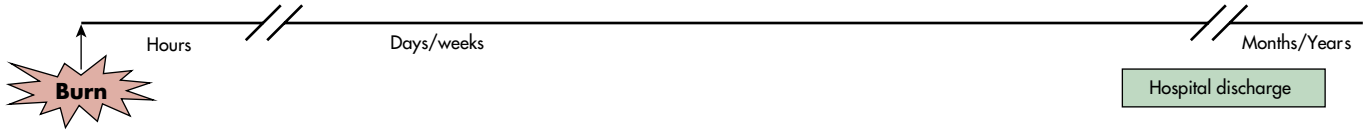

FIG. 2 The four major phases of burn care. Initial assessment and triage (phase I), resuscitation (phase II), burn wound coverage and critical care (phase III), and rehabilitation (phase IV). *CVP,* Central venous pressure; *DVT,* deep vein thromboses; *IV,* intravenous; *MAP,* mean arterial pressure; *Scv_{02},* central venous oxygen saturation; *TBSA,* total body surface area. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult*, ed 5, Philadelphia, 2019, Elsevier.)

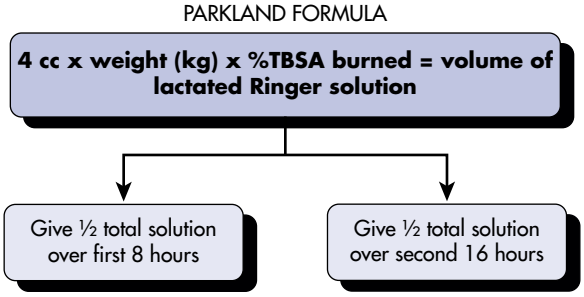

FIG. 3 Parkland formula. *TBSA,* Total body surface area. (From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.)

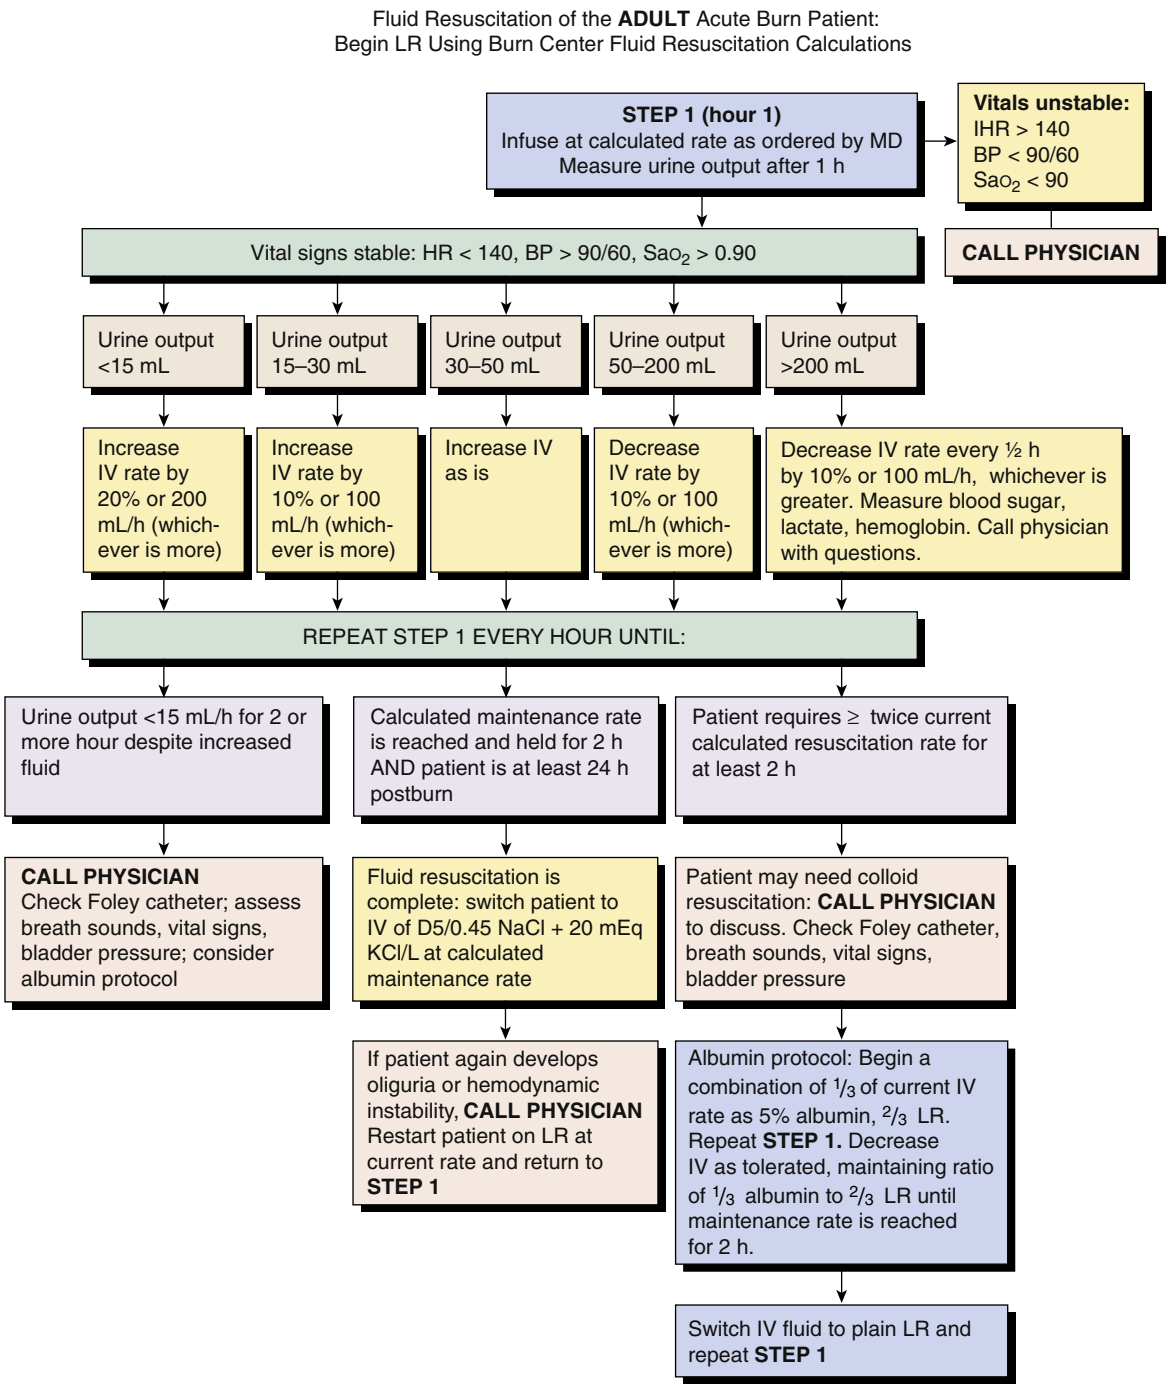

FIG. 4 Burn fluid resuscitation protocol used at the University of Utah. Physicians order an initial infusion rate of lactated Ringer solution based on Parkland formula calculations and indicate the target maintenance rate. The nursing staff measures hourly urine output and increases or decreases fluids based on this response. If patients experience unexpected changes in vital signs or do not respond appropriately, physicians are contacted. An option for the use of colloid-containing resuscitation is included for patients whose requirements fail to decline. This regimen permits close titration of fluids without requiring hourly physician input. *BP,* Blood pressure; *D5/0.45,* glucose 5.0% and sodium chloride 0.45%; *HR,* heart rate; *IHR,* intrinsic heart rate; *IV,* intravenous; *LR,* lactated Ringer solution; *MD,* physician; *Sao_2,* oxygen saturation. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

BOX 1 Mayes Equations to Calculate Energy Requirement after a Burn

Mayes equation for a 5- to 10-yr-old burn patient with injury <50% TBSA:

$$818 + 37.4\ (\text{weight in kilograms}) + 9.3 \times \text{TBSA burn}$$

Mayes equation for a 5.5-yr-old patient with a 45% TBSA scald burn weighing 20 kg:

$$818 + 37.4\ (20\ \text{kg}) + 9.3 \times 45\ \text{TBSA scald}$$

$$818 + 748 + 481.5 = 2047.5\ \text{calories/day}$$

TBSA, Total body surface area.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, WB Saunders.

BURN WOUND CARE BY BURN DEPTH Rx

GENERAL:

- Vigilant wound care with dressings to prevent evaporation and minimize threat of wound colonization and infection of nonintact skin
- Daily activity necessary to maintain function of burned extremity, decrease pain and swelling, and promote healing
- First-degree burns (skin intact):
  1. *Dressing:* None required (except to protect from injury); topical antibacterial agents NOT recommended
  2. *Other:* Emollients, cool compresses (avoid ice), if pruritic, trial of antihistamines
  3. *Prognosis:* Heals within 1 wk without scarring; may heal with pigmentary changes (limit by sunscreen and sun avoidance of area for 1 yr)
- Second-degree (superficial partial-thickness) burns without adherent exudate or eschar:
  1. *Blisters:* Sharp debridement of ruptured blisters; leave intact blisters. Quicker healing and reduced infections when intact blisters are not disturbed. Consider unroofing blisters that show no sign of resorption over several wks or contain cloudy fluid.
  2. *Dressing:* Topical antimicrobial ointment (e.g., Bactroban) or A&D ointment with nonadherent dressing twice a day. Alternate: Biosynthetic dressing (alginates, hydrofibers, or foam dressings)—many with silver as antimicrobial (absorb exudates, maintain moist environment, require fewer dressing changes, which reduces pain/anxiety).
  3. *Prognosis:* Heals with minimal scarring in 10 to 14 days. May heal with pigmentary changes (reduced with sunscreen and sun avoidance of area × 1 yr).
- Second-degree (deep partial-thickness) burns with adherent exudates; localized third-degree burns; cellulitic wounds:
  1. *Dressing:* Silver sulfadiazine 1%: Broader spectrum, better penetration of necrotic tissue than Bactroban, but inhibits epithelialization and promotes hypertrophic scarring in studies. Must stop use once exudates and eschar have separated from wound. Alternative: Enzymatic debrider (e.g., Santyl or Accuzyme)—chemically debrides devitalized tissue without harming healthy tissue.
  2. *Referral:* Burn specialist for consultation regarding need for excision and grafting.
  3. *Prognosis:* Deep second-degree burns heal with significant scarring, often take 3 to 4 wk to heal. If infected, convert to third-degree burns. Third-degree burns typically require skin graft, but small areas may heal from edges after wks.

DISPOSITION/FOLLOW-UP CARE

- Outpatient: Evaluate next day to assess level of injury, level of pain, and ability to manage dressing changes on own. If insufficient, daily evaluation until complete wound epithelialization recommended. Epithelialization: Tiny islands of epithelialization throughout wound. If no epithelialization after 2 wk, or subsequent evaluation reveals third-degree burn, referral to burn surgeon recommended. Box E2 describes common complications in burn patients.
- Following re-epithelialization, visits every 4 to 6 wk to monitor for hypertrophic scar formation (early referral to burn/scar specialist if occurs).
- Mortality rates higher in patients >60 yr of age, with burns >40% TBSA, or with inhalation injury. Long-term risk of developing squamous cell carcinoma of the skin within burn injury. Long-term skin monitoring necessary.

REFERRAL

Consultation of burn specialist or burn center referral per Table 2.

PEARLS & CONSIDERATIONS

COMMENTS

- In circumferential skin burns, look for compartment syndrome of limbs (e.g., tightening, progressive deterioration of peripheral motor and sensory exam findings, severe pain, and loss of arterial Doppler signals). Escharotomy may be necessary.
- If child abuse is suspected, social services at the hospital or child protective services must be contacted.
- Fig. E5 describes an algorithm for the treatment of chemical burns.

SUGGESTED READINGS

Kessides MC, Skelsey MK: Management of acute partial-thickness burns, *Cutis* 86:249-257, 2010.

Moss L: Treatment of the burn patient in primary care, *Adv Skin Wound Care* 23(11):517-524, 2010.

BOX E2 Common Complications in Burn Patients

Cardiovascular

- Endocarditis and suppurative thrombophlebitis are intravascular infections that typically present as fever and bacteremia without signs of local infection.
- Hypertension occurs in up to 20% of children and is best managed with β-adrenergic blockers.
- Venous thromboembolic complications are so infrequent in patients with large burns that routine prophylaxis is not routine in all programs. Iatrogenic catheter insertion complications are minimized by meticulous technique.

Pulmonary

- Carbon monoxide intoxication, best managed acutely with effective ventilation with pure oxygen, can be associated with delayed neurologic sequelae.
- Pneumonia may occur with or without antecedent inhalation injury and is treated with pulmonary toilet and antibiotics.
- Respiratory failure may occur early postinjury secondary to inhalation of noxious chemicals or later in the course (secondary to sepsis or pneumonia).

Neurologic

- Transient delirium occurs in up to 30% of patients and generally resolves with supportive therapy when the possibility of anoxia, metabolic disturbance, and structural lesions is eliminated by appropriate studies.
- Seizures most commonly result from hyponatremia or abrupt benzodiazepine withdrawal.
- Peripheral nerve injuries occur from direct thermal injury, compression from compartment syndrome or overlying inelastic eschar, major metabolic disturbances, or improper splinting techniques.
- Delayed peripheral nerve and spinal cord deficits develop wks or mos after high-voltage injury secondary to small vessel injury and demyelinization.

Hematologic

- Neutropenia and thrombocytopenia, as well as disseminated intravascular coagulation, are common indicators of impending sepsis and should prompt appropriate investigations.
- Global immunologic deficits associated with burn injury contribute to a high rate of infectious complications.

Renal

- Early acute renal failure follows inadequate perfusion during resuscitation or myoglobinuria.
- Late renal failure complicates sepsis and multi-organ failure or the use of nephrotoxic agents.

Adrenal

- Acute adrenal insufficiency secondary to hemorrhage into the gland presents as hypotension, fever, hyponatremia, and hyperkalemia.

Otolaryngologic

- Auricular chondritis secondary to bacterial invasion of cartilage results in rapid loss of viable tissue and is prevented by routine use of topical mafenide acetate on burned ears.
- Sinusitis and otitis media can be caused by transnasal instrumentation and are treated by relocation of tubes, antibiotics, and judicious surgical drainage.
- Complications of endotracheal intubation include nasal alar and septal necrosis, vocal cord erosions and ulcerations, tracheal stenosis, and tracheoesophageal and tracheoinnominate artery fistulas. The occurrence of such complications is minimized by compulsive attention to tube position, avoidance of oversized tubes, and attention to cuff pressures.

Gastrointestinal

- Hepatic dysfunction secondary to transient hepatic blood flow deficits and manifested as transaminase elevations is common during resuscitation from large burns and resolves with volume restitution. Late hepatic failure, beginning with elevations of cholestatic chemistries and progressing through coagulopathy and frank failure, complicates sepsis and multiorgan failure.
- Pancreatitis, beginning with amylase and lipase elevations and ileus and progressing through hemorrhagic pancreatitis, is generally coincident with splanchnic flow deficits early and sepsis-induced organ failures later in the hospital course.
- Acalculous cholecystitis can present as sepsis without localized symptoms or signs accompanied by rising cholestatic chemistries. A standard radiographic evaluation can be followed by bedside percutaneous cholecystostomy in unstable patients.
- Gastroduodenal ulceration secondary to splanchnic flow deficits that degrade mucosal defenses is extremely common and often life threatening if routine histamine-receptor blockers and antacids are not administered.
- Intestinal ischemia, which can progress to infarction, is secondary to inadequate resuscitation and splanchnic flow deficits.

Ophthalmologic

- Ectropia from progressive contraction of burned ocular adnexa results in exposure of the globe. This requires acute eyelid release. Tarsorrhaphy is rarely helpful, more often resulting in injury to the tarsal plate as contraction forces pull out tarsorrhaphy sutures.
- Corneal ulceration, which develops after initial epithelial injury or later exposure due to ectropion, can progress to full-thickness corneal destruction if secondary infection occurs. This is prevented by careful globe lubrication with topical antibiotics in the former case and acute lid release in the later.
- Symblepharon, or scarring of the lid to the denuded conjunctiva after chemical burns or corneal epithelial defects complicating toxic epidermal necrolysis, is prevented by daily examination and adhesion disruption with a fine glass rod.

Genitourinary

- Urinary tract infections are minimized by maintaining bladder catheters only when absolutely required and are treated with appropriate antibiotics. Neither catheterization nor colonic diversion is usually required for management of perineal and genital burns.
- Candida cystitis occurs in those patients treated with bladder catheters and broad-spectrum antibiotics. Catheter change and amphotericin irrigation for 5 days is generally successful. If infections are recurrent, the upper tracts should be screened ultrasonographically.

Musculoskeletal

- Burned-exposed bone is generally debrided with a dental drill until viable cortical bone is reached, which is then allowed to granulate and is autografted. Patients whose overall condition and wounds are appropriate are managed with local or distant flaps.
- Fractured and burned extremities are best immobilized with external fixators while overlying burns are grafted. Burn patients with coincident fractures in unburned extremities benefit from prompt internal fixation.
- Heterotopic ossification develops wks after injury, is seen most commonly around deeply burned major joints such as

BOX E2 Common Complications in Burn Patients—cont'd

the triceps tendon, and presents as pain and decreased range of motion. Most patients respond to physical therapy, but some require excision of heterotopic bone to achieve full function.

Soft Tissue

- Hypertrophic scar formation is a major cause of long-term functional and cosmetic deformities seen in burn patients. This poorly understood process is heralded by a secondary increase in neovascularity between 9 and 13 wk after epithelialization. Management options include grafting of deep dermal and full-thickness wounds, compression garments, judicious steroid injections, topical silicone products, and scar release and resurfacing procedures. NOTE: Systematic reassessment of seriously ill burn patients facilitates timely detection of complications. It is the very rare burn patient who does not experience complications during their care, particularly while in the intensive care unit. Unfortunately, many common burn complications are obscured by the fevers and hyperdynamic physiology that accompany a large burn.

BASIC INFORMATION

DEFINITION

Bursitis is an inflammation of a bursa, which is a thin-walled, synovial-lined sac. A bursa functions as a cushion to reduce friction while also facilitating movement of tendons and muscles over bony prominences. Olecranon bursitis and prepatellar bursitis are the most common, usually due to chronic microtrauma from repetitive pressure or activity.

SYNONYMS

Student elbow, miner elbow, draftsman elbow (olecranon bursitis)
Housemaid knee, carpet-layer knee (prepatellar bursitis)
Weaver bottom (ischial gluteal bursitis)
Baker cyst (gastrocnemius-semimembranosus bursa)
Pump bumps (subcutaneous calcaneal bursitis)
Pes anserine bursitis (goose foot, insertion of conjoined tendon into medial knee)

ICD-10CM CODES

M70.20	Other shoulder lesions, unspecified shoulder
M70.40	Olecranon bursitis, unspecified elbow
M70.60	Trochanteric bursitis, unspecified hip
M70.70	Other bursitis of hip, unspecified hip
M71.20	Other specified enthesopathies of unspecified lower limb, excluding foot
M75.80	Prepatellar bursitis, unspecified knee
M76.899	Synovial cyst of popliteal space [Baker], unspecified knee
M77.50	Other enthesopathy of unspecified foot

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Local swelling, tenderness, erythema, warmth over the site of bursa is common with prepatellar and olecranon bursitis.
- Subacromial bursitis may present with chronic shoulder pain, worse with overhead and repetitive activities, without weakness or stiffness.
- Range of motion may be markedly limited in septic arthritis, whereas ROM is relatively preserved in nonseptic bursitis.
- Subacromial/subdeltoid bursitis and trochanteric bursitis may also be found in polymyalgia rheumatica (PMR), thus can present with symptoms of PMR.

ETIOLOGY

- Acute traumatic
- Chronic microtrauma from repetitive activity or pressure
- Infection (septic bursitis)—spread from contiguous skin or soft tissue infection (*Staphylococcus aureus* causative in >80%)
- Crystal diseases (e.g., gout, pseudogout)
- Systemic inflammatory arthritis, particularly rheumatoid arthritis
- Bleeding (from diathesis, anticoagulation, or trauma)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute monoarthritis caused by septic arthritis or crystal arthritis (gout, pseudogout)
- Tendinitis, tenosynovitis
- Cellulitis

WORKUP

Bursal fluid aspiration: Send for Gram stain, culture and sensitivity, cell count, and crystal analysis

IMAGING STUDIES

- Plain radiography can rule out foreign body penetration and other bone or joint problems such as fracture (Fig. E1)
- MRI to define soft tissue involvement
- Musculoskeletal ultrasound to visualize superficial and deep bursae; assess inflammatory activity with Doppler and directly guide aspiration/injection

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid direct pressure or repetitive irritation
- Joint protection (e.g., kneeling pads, compression wraps)
- Rest, ice, elevation for acute phase
- Physical therapy
- Activity modification

ACUTE GENERAL Rx

- Septic:
  1. Appropriate antibiotic coverage and drainage. If MSSA, use nafcillin or oxacillin 2 g IV q4h or dicloxacillin 500 mg PO qid. If MRSA, use vancomycin 15 to 20 mg/kg IV q8-12h or linezolid 600 mg PO bid
  2. Serial aspirations of purulent fluid or surgical drainage may be indicated
- Nonseptic:
  1. Aspiration of bursal fluid or blood from acute trauma
  2. Nonpharmacologic therapy
  3. Traumatic bursitis may respond well to aspiration and corticosteroid injection
  4. Inflammatory arthritis such as gout or RA: Treat underlying condition with specific therapies and with systemic antiinflammatory medications for active disease; can consider intrabursal injection of steroids

CHRONIC Rx

- Aspiration and drainage of fluid can provide symptomatic improvement if large fluid collection, followed by compression dressing to prevent fluid reaccumulation
- Steroid injection into nonseptic bursa if inflammatory, recurrent, or persistently symptomatic (40 mg triamcinolone mixed with 1 to 3 ml lidocaine, depending on size of bursa)
- Oral NSAIDs, over-the-counter analgesics
- Patients in whom conservative therapy fails to resolve symptoms of chronic inflammatory may be considered for surgical bursectomy

DISPOSITION

- Conservative nonsurgical treatment is effective in most cases. Surgical drainage may be indicated for loculated bursitis or if septic. Recurrent bursitis affecting function may require surgical bursectomy.

REFERRAL

Orthopedic consultation may be needed as part of treatment of septic bursitis, or for persistent or recurrent bursitis that interferes with daily function.

PEARLS & CONSIDERATIONS

Bursae in patients with RA are not usually the sole site of active flare. Therefore, in patients with RA, acute bursitis should be considered septic bursitis until proven otherwise.

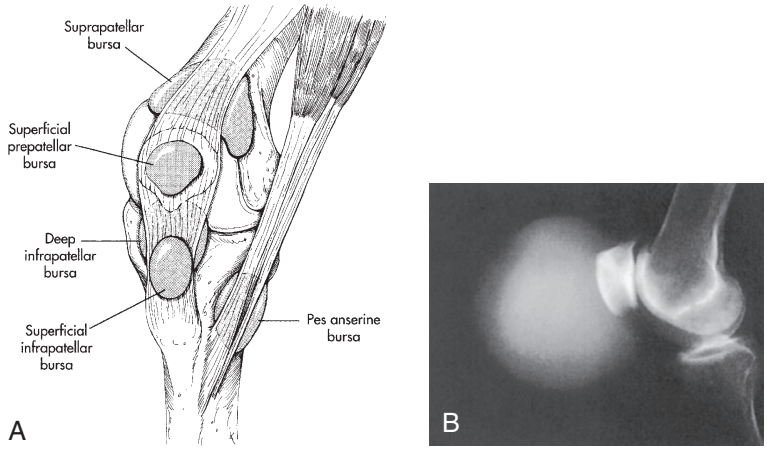

FIG. E1 A, Bursae around the knee. **B,** Markedly swollen prepatellar bursa. (From Scudieri G [ed]: *Sports medicine principles of primary care,* St Louis, 1997, Mosby.)

COMMENTS

- Scapulothoracic bursitis is underrecognized and undertreated. It results from friction between superomedial angle of scapula and adjacent second and third ribs. Crepitus, snapping, and tenderness are suggestive findings; it can also cause chest wall pain.
- Do not incise and drain sterile bursae because chronic draining sinus tract may develop and risk iatrogenic septic bursitis.
- In bursitis caused by infectious or systemic inflammatory disorders, the leukocytosis in bursal fluid may be substantially less intense than the elevations in the joint fluid.
- Investigate crystal-induced bursitis for underlying metabolic or hematologic diseases (hemochromatosis, hyperparathyroidism [calcium pyrophosphate deposition disease]), and for hyperuricemia (gout).

BASIC INFORMATION

DEFINITION

Calcium pyrophosphate dihydrate crystal deposition (CPPD) disease refers to the precipitation of calcium pyrophosphate dihydrate (CPP) in connective tissues that may be asymptomatic or may be associated with several clinical syndromes, including acute and chronic arthritis. CPP was formerly abbreviated and commonly referred to as "CPPD," but the abbreviation is now reserved for "CPP deposition." Alternative names (Table 1) representing specific clinical or radiographic features of CPPD disease include pseudogout, chondrocalcinosis, and pyrophosphate arthropathy.

Pseudogout/acute CPP crystal arthritis is used to describe acute attacks of CPP crystal-induced arthritis that clinically resembles the arthritis that is commonly encountered in gout. The term *acute CPP crystal arthritis* is now preferred in place of *pseudogout*.

Chondrocalcinosis (CC) refers to radiographic calcification in hyaline cartilage and/or fibrocartilage and does not confirm the diagnosis of CPP-related arthritis as it can be present in other types of crystal deposition diseases or be asymptomatic.

Pyrophosphate arthropathy is the term used for a chronic structural arthropathy related to CPP deposition.

SYNONYMS

Calcium pyrophosphate dihydrate crystal deposition disease
CPP crystal deposition disease
CPPD
Chondrocalcinosis (CC)
Pseudogout
Pyrophosphate arthropathy

ICD-10CM CODES

M11.2	Other chondrocalcinosis
M11.9	Crystal arthropathy, unspecified
M11.8	Other specified crystal arthropathies
M11.1	Familial chondrocalcinosis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- The epidemiology of CPPD crystal deposition is described in Table 2.
- Most linked with advancing age (average age of 72).

GENETICS: Familial forms

- Associated with *ANKH* (ankylosis human) gene, which functions to transport inorganic pyrophosphate (PPi) out of cells, or the osteoprotegerin gene (TNFRSF11B).
- Familial mutations can increase extracellular PPi levels and lead to onset of CPPD disease in the third or fourth decade of life.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- *Acute* CPP *crystal arthritis/pseudogout:* Monoarticular attacks most commonly involve the knee and wrist but can be polyarticular (Fig. E1). Patients, especially the elderly, can have systemic manifestations such as fever and altered mental status. Situations that may trigger acute CPPD crystal arthritis are described in Box E1
- Asymptomatic disease ("asymptomatic CPPD")
- Pseudogout (acute CPP crystal arthritis)
- Pseudo-RA (chronic CPP crystal inflammatory arthritis): Symmetric polyarthritis
- Pseudo-OA, with or without superimposed acute attacks (OA with CPPD)
- Pseudo-neuropathic joint disease
- Crowned-dens syndrome caused by crystal deposition in the ligamentum flavum of the cervical spine, either asymptomatic or causing acute neck pain
- Pseudo-polymyalgia rheumatica (pseudo-PMR): Pain and stiffness in the neck and shoulder girdle mimicking PMR

ETIOLOGY

- Idiopathic
- Familial
- Trauma
- Metabolic and endocrine disorders (Table 3): Hyperparathyroidism, hypophosphatasia, hemochromatosis, hypomagnesemia, Gitelman syndrome, Bartter syndrome, gout, ochronosis, acromegaly, Wilson disease, familial hypocalciuric hypercalcemia, X-linked hypophosphatemic rickets

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gouty arthritis (Table 4)
- Septic arthritis
- RA
- Spondyloarthritis (ReA, PsA)
- PMR

Table 5 describes metabolic diseases predisposing to CPPD disposition. Section II describes the differential diagnosis of acute monoarticular and oligoarticular arthritis and crystal-induced arthritides. An algorithm for evaluation and treatment of CPPD is shown in Fig. 2.

LABORATORY TESTS

- Arthrocentesis with presence of weakly positive birefringent rhomboid-shaped crystals by compensated polarized light microscopy (Fig. E3).
- Synovial fluid should always be analyzed for cell count with differential, crystals, Gram stain, and culture because acute CPP crystal arthritis/pseudogout and septic arthritis can co-exist.
- Evaluate for possible metabolic causes, especially in younger patients aged <55 yr or patients with florid polyarticular disease. Box 2 describes screening blood tests for metabolic diseases associated with CPPD crystal deposition.

IMAGING STUDIES

- Plain radiographs (Figs. E4, E5, and E6) often reveal CC located parallel to subchondral bone.
  1. Classic locations for CC (Fig. E1) include knee menisci (Fig. E7), wrist triangular fibrocartilage, symphysis pubis, and glenoid and acetabular labra.
- Musculoskeletal ultrasound can detect deposition of CPP crystals within the hyaline

TABLE 1 Nomenclature of Calcium Pyrophosphate and Associated Syndromes

Definition	Old Terms	EULAR Recommendations	Preferred Term (Abbreviation)
Radiographic correlate of CPPD	Chondrocalcinosis, chondrocalcinosis articularis	Chondrocalcinosis	Chondrocalcinosis (CC)
Acute inflammatory arthritis caused by CPP crystals	Pseudogout	Acute CPP crystal arthritis	Acute CPP crystal arthritis
Calcium pyrophosphate dihydrate crystals	Calcium pyrophosphate dehydrate; calcium pyrophosphate dihydrate	Calcium pyrophosphate crystals	Calcium pyrophosphate crystals (CPP crystals)
All clinical syndromes associated with CPP crystals	Calcium pyrophosphate dehydrate deposition disease	None	Calcium pyrophosphate deposition disease (CPPD)
Chronic arthritis caused by CPP crystals ± inflammation	Calcium pyrophosphate dihydrate deposition disease: Pyrophosphate arthropathy; pseudorheumatoid arthritis; pseudoosteoarthritis	Chronic CPP crystal arthritis, OA with CPPD	Chronic CPP crystal arthritis, OA with CPPD
Deposition of calcium pyrophosphate crystals in joints or tissue with or without clinical symptoms	Calcium pyrophosphate dihydrate deposition	CPPD	Calcium pyrophosphate deposition (CPPD)

TABLE 2 Epidemiology of Calcium Pyrophosphate Dihydrate Crystal Deposition

Age Association	Rises with Age
Sex distribution	(F:M) 1:1
Chondrocalcinosis prevalence	8.1% (age range 63 to 93)
Pyrophosphate arthropathy prevalence	3.4% (age range 40 to 89)
Geography	Appears ubiquitous
Genetic associations	Mutations of *ANKH* gene on chromosome 5p (CCAL2) and unknown genes on chromosome 8q (CCAL1)

From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.

cartilage and/or fibrocartilage. In contrast to urate crystal deposits in gout, CPP crystals often deposit within the substance of the hyaline cartilage and fibrocartilage, providing a means to distinguish CPP from urate deposition that occurs on the surface of the hyaline cartilage as seen in gout (Fig. E8).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

General measures such as immobilization of inflamed joint

ACUTE GENERAL Rx

- Monoarticular pseudogout:
  1. Aspiration followed by intraarticular corticosteroid injection (often superior to systemic treatment in the elderly)
- Polyarticular pseudogout:
  1. Oral corticosteroids, colchicine, or NSAIDs, if not contraindicated

CHRONIC GENERAL Rx

Prophylaxis: Daily low-dose colchicine 0.6 mg twice daily or once daily as tolerated

- Pseudo-RA or refractory disease: Hydroxychloroquine or methotrexate
- Anakinra (Interleukin-1 receptor antagonist): Treatment and prophylaxis of polyarticular acute CPP crystal arthritis unresponsive to oral corticosteroids
- Treat underlying metabolic disease
- Management options for CPPD are summarized in Boxes E3 and E4

DISPOSITION

Structural joint damage may occasionally occur, requiring arthroplasty in rare cases.

REFERRAL

Rheumatology

TABLE 3 Diseases Associated with Calcium Pyrophosphate Dihydrate Crystal Deposition Disease

Disease	Strength of Evidence for a Link with CPPD	Recommended Testing
Hyperparathyroidism	Strong	Calcium, parathyroid hormone level
Hemochromatosis	Strong	Fe, TIBC, ferritin, C282Y
Hypophosphatasia	Strong	Alkaline phosphatase
Hypomagnesemia	Strong	Magnesium
Gout	Strong	Synovianalysis
Rheumatoid arthritis	Moderate	Clinical judgement
Osteoporosis	Moderate	Bone density if warranted

CPPD, Calcium pyrophosphate dihydrate crystal deposition disease; *TIBC,* total iron-binding capacity.

BASIC INFORMATION

DEFINITION

Calcium-alkali syndrome is the triad of hypercalcemia, metabolic alkalosis, and renal insufficiency due to consumption of large amounts of calcium and absorbable alkali. For conventional diagnostic purposes, only hypercalcemia with an appropriate history of ingestions must be present.

SYNONYM

Milk-alkali syndrome

PRESENTATIONS

Calcium-alkali syndrome presents in one of three patterns:

1. Acute: This stage occurs after approximately 1 week of excessive calcium and alkali intake. Symptoms are attributable to hypercalcemia and may include nausea, vomiting, weakness, mental status depression, and confusion. Metabolic alkalosis is present with a normal or elevated serum phosphorus level. An elevated serum creatinine reflects acute kidney injury. Cessation of exogenous calcium and alkali leads to resolution of signs and symptoms.
2. Subacute or intermediate ***(Cope syndrome):*** Patients typically are encountered after milk and alkali have been ingested intermittently for yrs. Affected patients demonstrate symptoms of acute and chronic hypercalcemia and respond to medication withdrawal with gradual improvement. Kidney function is often mildly and chronically impaired.
3. Chronic form ***(Burnett disease):*** Symptoms of chronic hypercalcemia present after prolonged high calcium and alkali intake and include polyuria, polydipsia, myalgias, and pruritus. Physical evidence of metastatic calcification is detectable as nephrocalcinosis and band keratopathy. Laboratory findings are like those of the acute syndrome. Muscle aches and pruritus improve slowly as the plasma calcium concentration gradually improves. Minimal or no improvement in kidney function occurs due to irreversible damage.

ICD-10CM CODE
E83.52 Disorders of calcium metabolism

EPIDEMIOLOGY & DEMOGRAPHICS

In the early twentieth century, the calcium-alkali syndrome was associated with the Sippy antacid regimen for peptic ulcer disease that entailed ingestion of large amounts of calcium salts, particularly from milk and absorbable bicarbonate compounds. Kidney injury and alkalosis were followed by hypercalcemia. Following the developments of type 2 histamine receptor blockers and proton pump inhibitors, the syndrome virtually disappeared. However, since the 1980s, a resurgence of hypercalcemia associated with calcium-containing product use for osteoporosis prevention occurred. In chronic kidney disease patients, calcium carbonate use as a phosphate binder instead of aluminum hydroxide produced the "calcium-alkali" syndrome. This updated term supplants "milk-alkali syndrome," as milk is no longer the source of calcium. The calcium-alkali syndrome was the third-most cause of hypercalcemia (12%) in hospitalized patients from 1990 to 1993, following hypercalcemia of malignancy and primary hyperparathyroidism.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Asymptomatic hypercalcemia:
  1. Less than half of all cases are incidental findings of hypercalcemia on random laboratory testing.
- Symptomatic hypercalcemia:
  1. Symptoms: Nausea, vomiting, anorexia, fatigue, vague abdominal pain, nephrolithiasis- and pancreatitis-related pain, constipation, myalgia, confusion, and psychosis. In chronic cases, polyuria and polydipsia may be reported.
  2. Physical examination and other testing: Mental status changes include anxiety, depression, and cognitive dysfunction; also shortened QT segment interval.

ETIOLOGY

Overconsumption of supplemental calcium of 3 to 20 g daily in association with volume depletion, renal impairment, or thiazide diuretic use is the most common etiology. The resulting hypercalcemia reduces glomerular filtration of calcium and induces salt-wasting reducing extracellular fluid volume that further lowers glomerular filtration and increases bicarbonate reabsorption with metabolic alkalosis. Vomiting or diuretic-induced volume depletion worsen hypercalcemia and alkalosis. The paradigm of demographics has shifted from young males with peptic ulcer disease in the nineteenth century to postmenopausal women, solid organ transplant recipients, bulimic patients, pregnant women, dialysis patients, and elderly individuals who experience greater bone loss and are prone to developing hypercalcemia in the presence of excess calcium supplements. Betel nut chewing, a practice in Asia and the South Pacific, is associated with calcium-alkali syndrome. The nuts are bitter and coated with a compound that is converted to bicarbonate, fostering metabolic alkalosis.

PATHOGENESIS

Calcium alkali syndrome has a generation and maintenance phase. Generation phase of hypercalcemia is due to the increased calcium absorption, decreased renal excretion, and saturation of bone buffering of calcium. Maintenance phase is promoted by hypercalcemia-induced volume depletion from diuresis and natriuresis by activation of CaSR in the thick ascending loop of Henle, a decrease in GFR which decreases filtration of calcium, and an increase in renal absorption of calcium as a result of volume depletion and metabolic alkalosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hypercalcemia from other causes includes primary hyperparathyroidism, certain malignancies, and granulomatous disorders including tuberculosis, sarcoidosis, and silicosis.

LABORATORY TESTS

- Elevated serum ionized calcium (wide variation reported)
- Elevated BUN and serum creatinine from acute kidney injury or chronic kidney disease
- Elevated serum bicarbonate and arterial pH from metabolic alkalosis
- Parathyroid hormone, usually suppressed by hypercalcemia in calcium-alkali syndrome, may be elevated, particularly if evaluated after treatment initiation
- Serum phosphorus level is variable (historically high with milk ingestion but low with calcium carbonate ingestion due to gut phosphate binding)
- Hypomagnesemia occasionally

TREATMENT

NONPHARMACOLOGIC THERAPY

Hemodialysis is indicated rarely for severe renal dysfunction or markedly symptomatic hypercalcemia.

ACUTE GENERAL Rx

- Discontinuation of all calcium and bicarbonate supplementation.
- Volume repletion by intravenous saline, followed by loop diuretic administration to increase urinary calcium excretion.
- Transient hypocalcemia can be seen when patients are treated with loop diuretic followed by rebound rise in PTH, which is something unique to calcium alkali syndrome as the hypercalcemic stimulus is suddenly removed.
- Bisphosphonates are avoided as they cause prolonged suppression of serum calcium in calcium alkali syndrome.
- Patient education to limit future calcium supplementation from over-the-counter calcium supplements (TUMS) and antacids containing calcium carbonate (Calcarb, CitraCal, Caltrate).

PROGNOSIS

Hypercalcemia and associated symptoms resolve with withdrawal of excess calcium supplementation and treatment of hypercalcemia. Acute cases typically resolve in 1 to 2 days while chronic cases take longer. Patients initially presenting with kidney failure may incur residual kidney damage.

DISPOSITION

Treatment is determined by degree of hypercalcemia and symptoms. Hospitalization is required for symptomatic patients or for patients whose

total serum calcium is >11.5 mg/dl and who may require IV volume repletion and other intensive treatments for hypercalcemia.

REFERRAL

- Nephrology

PEARLS & CONSIDERATIONS

COMMENTS

Detailed history of dietary supplements and over-the-counter medications (see Table E1) can provide important clues. Many patients do not list dietary supplements as a medication.

AUTHORS: **Jesse Goldman, MD, FASH,** and **M. Owais Hanif, MD**

TABLE E1 Potential Sources of Alkali

Alkali/Alkali Precursor	Source
Bicarbonate	Sodium bicarbonate: Pills, intravenous solutions Proprietary brands, e.g., Alka-Seltzer baking soda Potassium bicarbonate: Pills, oral solutions
Lactate	Lactated Ringer solution, peritoneal dialysis solutions
Acetate, glutamate, propionate	Parenteral nutrition
Citrate	Blood products, plasma exchange, potassium supplements, alkalinizing agents
Calcium compounds (alkalinizing effect minimal when given by mouth), acetate, citrate, and carbonate	Calcium supplements, phosphate binders

BASIC INFORMATION

DEFINITION

Carcinoma of unknown primary (CUP) refers to a diverse group of malignancies for which the anatomic site of origin cannot be determined despite extensive investigations.

SYNONYMS

Cancer NOS
Cancer unspecified site
Malignancy unspecified site
CUP

ICD-10CM CODE
C80.1 Malignant (primary) neoplasm, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- CUP accounts for about 4% of all cancers, and the annual incidence in the United States is 7 to 12 cases per 100,000 persons.
- It is the seventh most frequent common cause of cancer and the fourth most common cause of cancer death. It predominantly occurs in adults and is more common in males.
- In the United States, an estimated 31,810 new cases are expected in 2018. CUP incidence rates have been decreasing since the early 1980s, 3.6 % per yr in the last two decades.
- Most cases of CUP are carcinomas, which are divided into adenocarcinomas (90%), squamous cell carcinomas (5%), and undifferentiated carcinomas (5%).
- Recent data suggest that the risk of CUP is substantially increased in heavy smokers and to a lesser degree increased in obese patients.
- There is a variable rate of mutations detected in CUP (18%-30%). The tumor suppressor gene *p-53* has overexpression rates (40% to 50%) or mutation rates (25% to 40%) that are comparable to that seen in other solid tumors. The evaluation of VEGF-A (vascular endothelial growth factor-A, angiogenesis factor) and matrix metalloproteinases (enzymes that degrade stroma) showed that these are universally expressed and active angiogenesis is present in CUP.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical findings can be variable and include generalized and organ-specific findings.
- General findings can include cachexia, pallor, edema, icterus, edema, skin rash, muscle wasting among others.
- Organ-specific findings are related to the dysfunction of the underlying organ(s) involved with CUP.
- The clinical course is often highlighted by a short presentation history, with symptoms and signs associated with metastatic sites, early dissemination, aggressive clinical course, and occasionally an unpredictable metastatic pattern.
- Multiple organs are involved at diagnosis in up to half of patients.
- The clinicopathologic subsets comprising CUP are shown in Table 1.

DIAGNOSIS

WORKUP

- Comprehensive medical history
- Complete physical examination with particular attention to skin, lymph node sites, organ enlargement, and testes; also rectal examination and pelvic examination (in women) (Table 2)
- Histopathology review of biopsy specimens

LABORATORY TESTS

- Complete blood count.
- Comprehensive chemistry panel.
- Urine analysis.
- Stool for occult blood.
- Tumor markers (in selected cases): Prostate-specific antigen (PSA), β-human chorionic gonadotrophin, α-fetoprotein.
- Adequate tissue biopsy with immunohistochemical (IHC) staining is done to guide broad diagnostic category assignments—carcinoma, melanoma, sarcoma, or lymphoma. Commonly used immunoperoxidase stains to assist in the differential diagnosis of carcinoma of unknown primary cancer are summarized in Table 3.
- Subtyping with IHC panels helps further classifying into adenocarcinoma, squamous carcinoma, germ cell tumor, neuroendocrine, thyroid, hepatocellular, or renal origin.
- Stepwise approach for IHC-derived diagnosis of likely site of origin is depicted in Table 4.
- In up to 25% cases, a single site of origin can be narrowed down by IHC staining (e.g., TTF-1 positive and CK-1 positive lung cancer profile).
- Molecular diagnosis is carried out by commercially available multi-gene assays that utilize micro-array or polymerase chain reaction assays and can assist in finalizing diagnosis in up to 80% to 90% of cases in which initial IHC staining has been inconclusive.

IMAGING STUDIES

- CT scans of the chest, abdomen, and pelvis; also CT of the neck in case of neck lymphadenopathy
- For selected cases
  1. PET scan
  2. Mammography and/or breast MRI
  3. Testicular ultrasonography

TABLE 1 Clinicopathologic Subsets of Patients with CUP

	Median Age (Yrs)	Sex of Patients (M/F)	Histopathology
Lymph Nodes			
Mediastinal retroperitoneal	<50	70%/30%	UDF or PDF
Axillary	52	0%/100%	Adenocarcinoma (WDF, MDF, or PDF)
Cervical	57-60	80%/20%	SCC
Inguinal	58	50%/50%	UDF, SCC, mixed SCC and adenocarcinoma
Peritoneal Cavity			
Primary peritoneal in women	55-65	0%/100%	Adenocarcinoma (serous papillary)
Ascites of other unknown origin	–	–	Adenocarcinoma (MDF or PDF; mucin; with or without signet ring cells)
Neuroendocrine tumors	63	60%/40%	PDF with neuroendocrine features; low-grade neuroendocrine cancers; small-cell anaplastic cancers
Liver (mainly) or other organs, or both	62	61%/39%	Adenocarcinoma (MDF or PDF)
Lungs			
Pulmonary metastases	–	–	Adenocarcinoma (WDF, MDF, or PDF)
Pleural effusions	–	–	Adenocarcinoma (MDF or PDF)
Bones (one or more)	–	–	Adenocarcinoma (WDF, MDF, or PDF)
Brain (one or more)	51-55	M>F	Adenocarcinoma (WDF, UDF, or PDF); SCC

CUP, Cancer of unknown primary; *F,* women; *M,* men; *MDF,* moderately differentiated; *PDF,* poorly differentiated; *SCC,* squamous cell carcinoma; *UDF,* undifferentiated; *WDF,* well differentiated.
From Pavlidis N, Pentheroudakis G: Cancer of unknown primary site, *Lancet* 379(9824):1428-1435, 2012.

TREATMENT

- CUP patients often require early supportive care for their advanced cancer; also there is elevated psychosocial distress with the uncertainties of diagnosis and treatment options. Anxiety and depression are more common in CUP patients compared to patients with known primaries.
- Treatment is based according to the most likely site of origin for the cancer, with systemic chemotherapy typically being the mainstay of therapy.
- Treatment is typically palliative, and standard chemotherapy consists of platinum plus taxane combinations. In addition, gemcitabine-based regimens can be used.
- Next-generation gene sequencing and in situ hybridization techniques in a large study of 1806 CUP cases were able to identify potential biomarkers predictive of therapeutic efficacy in 96% of cases. Additionally, biomarkers associated with a potential lack of benefit were identified in numerous cases, which could further refine the management of patients with CUP.

TABLE 2 Recommended Evaluation Following Initial Light Microscopic Diagnosis

Diagnosis	Clinical Evaluation*	Special Pathologic Studies
Adenocarcinoma (or poorly differentiated adenocarcinoma)	PET CT of chest, abdomen; men: Serum psa; women: Mammogram; additional directed radiologic or endoscopic studies to evaluate abnormal symptoms, signs, laboratory values	Men: PSA stain; women: Estrogen and progesterone receptor stains (if clinical features suggest metastatic breast cancer)
Poorly differentiated carcinoma	PET CT of chest, abdomen; serum hCG, AFP; additional directed radiologic or endoscopic studies to evaluate abnormal symptoms, signs, laboratory values	Immunoperoxidase staining; electron microscopy (if immunoperoxidase stains indeterminate)
Squamous carcinoma, cervical nodes	PET direct laryngoscopy with visualization; biopsy of nasopharynx, pharynx, hypopharynx, larynx; fiberoptic bronchoscopy (if laryngoscopy is negative)	—
Squamous carcinoma, inguinal nodes	PET complete examination of perineal area (including pelvic examination); anoscopy cystoscopy	—

*In addition to a history, physical examination, complete blood cell counts, chemistry profile, and chest radiograph.
AFP, α-Fetoprotein; *CT*, computed tomography; *hCG*, human chorionic gonadotropin; *PET*, positron emission tomography; *PSA*, prostate-specific antigen.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 25, Philadelphia, 2016, Saunders.

TABLE 3 Commonly Used Immunoperoxidase Stains to Assist in the Differential Diagnosis of Carcinoma of Unknown Primary Cancers

Primary Tissue Stain	Immunoperoxidase Stain
Lung cancer	Thyroid transcription factor (TTF-1), surfactant protein A precursor (SP-A1)
Breast cancer	Estrogen receptor (ER), gross cystic disease fibrous protein-15 (GCDFP-15), mammaglobin, Her-2/neu, GATA3
Lymphoma	Leukocyte common antigen (LCA), CD3, CD4, CD5, CD20, CD45
Gastrointestinal cancers	CK7, CK20, CDX-2, carcinoembryonic antigen (CEA)
Müllerian or ovarian	CK7, estrogen receptor (ER), WT-1, PAX-8, PAX2
Prostate cancer	PSA, alpha-methylacyl CoA racemase/P504S (AMACR/P504S), P501S (prostein), and prostate-specific membrane antigen (PSMA), NKX3-1
Germ cell tumor	β-hCG, αFP, OCT3/4, CKIT, CD30 (embryonal), SALL4
Hepatocellular cancers	Hep Par-1, arginase-1 (Arg-1), Glypican-3
Sarcoma	Desmin1, factor VIII, CD31, smooth muscle actin for leiomyosarcoma, MyoD1 for rhabdomyosarcoma
Renal cell cancer	RCC, CD10, PAX-8
Neuroendocrine tumor	Chromogranin, synaptophysin, CD56
Melanoma	S100, vimentin, HMB-45, tyrosinase and Melan-A, SOX-10
Urothelial	CK7, CK20, thrombomodulin, uroplakin III
Mesothelioma	Calretinin, WT-1, D2-40, mesothelin

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

- In another study of 442 patients with CUP, the use of targeted clinical-grade, next-generation sequencing resulted in the detection of alterations in circulating tumor DNA in 80% of patients. Among the patients harboring characterized alterations, distinct genomic profiles were observed in the majority of cases exhibited potentially targetable alterations with currently available biologic therapies.
- Favorable and unfavorable CUP subsets are shown in Table 5.
- ***Favorable CUP:***
  1. Women with peritoneal adenocarcinoma when treated as advanced ovarian cancer with surgical cytoreduction and adjuvant systemic chemotherapy can have median survivals in the 36-mo range.
  2. Patients with a midline tumor characteristically treated as germ cell tumors have median survivals of 12 mo.
  3. Patients with poorly differentiated neuroendocrine cancers are treated with combination platinum-containing chemotherapy and median survivals are in the 15-mo range.
  4. Women with axillary nodal adenocarcinoma are approached as breast cancers with treatment plans incorporating axillary and breast surgery followed by adjuvant chemotherapy, hormone therapy and radiotherapy; survival rates are comparable to similarly staged breast cancers.
  5. Patients with metastatic squamous neck nodal cancer are treated as head–neck cancers with chemoradiotherapy and/or neck dissection.
  6. Patients with a colon adenocarcinoma profile are treated with systemic regimens as in metastatic colorectal cancers with median survivals in the 24-mo range.
  7. Men with blastic bone metastases and elevated prostate specific antigen are treated with initial androgen deprivation therapy and later on with systemic chemotherapy.
- ***Unfavorable CUP:***
  1. Account for 75% to 80% of all CUP patients.
  2. The most common presentation is advanced visceral disease, often with liver metastases; median survivals with systemic platinum and taxane-containing chemotherapy are typically in the range of 6 to 7 mo.

DISPOSITION

Newer clinical practice guidelines recommend that gene panel testing be routinely undertaken to support diagnosis based on the findings of genomic mutations and to select a therapeutic drug that is likely to be effective.

TABLE 4 Immunohistochemical Approaches for Diagnosis of CUP

	Diagnosis
Step One	
AE1 or AE3 pan-cytokeratin	Carcinoma
Common leukocyte antigen	Lymphoma
S100; HMB-45	Melanoma
S100; vimentin	Sarcoma
Step Two	
CK7 or CK20; PSA	Adenocarcinoma
PLAP; OCT4; AFP; human chorionic gonadotropin	Germ cell tumors
Hepatocyte paraffin1; canalicular pCEA, CD10, or CD13	Hepatocellular carcinoma
RCC; CD10	Renal cell carcinoma
TTF1; thyroglobulin	Thyroid carcinoma
Chromogranin; synaptophysin, PGP9.5; CD56	Neuroendocrine carcinoma
CK5 or CK6; p63	Squamous cell carcinoma
Step Three	
PSA; PAP	Prostate
TTF1	Lung
GCDFP-15; mammaglobin; ER	Breast
CDX2; CK20	Colon
CDX2 (intestinal epithelium); CK20; CK7	Pancreas or biliary
ER; CA-125; mesothelin; WT1	Ovary

Step one detects broad type of cancer. Step two detects subtype. Step three detects origin of adenocarcinoma. Positive results with any of these stains indicates a tumor is present, but without absolute certainty.

AFP, α-Fetoprotein; *CA-125,* cancer antigen 125; *ER,* estrogen receptor; *GCDFP-15,* gross cystic disease fluid protein 15; *OCT4,* octamer-binding transcription factor 4; *PAP,* prostatic acid phosphatase; *pCEA,* polyclonal carcinoembryonic antigen; *PLAP,* placental alkaline phosphatase; *PSA,* prostate-specific antigen; *RCC,* renal cell carcinoma antigen *TTF1,* thyroid transcription factor 1; *WT1,* Wilms tumor 1.

From Pavlidis N, Pentheroudakis G: Cancer of unknown primary site, *Lancet* 379:1428-1435, 2012.

TABLE 5 Prognostic Classification of CUP Patients

Favorable Subset
Women with papillary adenocarcinoma of the peritoneal cavity
Women with adenocarcinoma involving the axillary lymph nodes
Poorly differentiated carcinoma with midline distribution
Poorly differentiated neuroendocrine carcinoma
Squamous cell carcinoma involving cervical lymph nodes
Adenocarcinoma with a colon-cancer profile (CK20+, CK7−, CDX2+)
Men with blastic bone metastases and elevated prostate-specific antigen (adenocarcinoma)
Isolated inguinal adenopathy (squamous carcinoma)
Patients with one small, potentially resectable tumor
Unfavorable Subset
Adenocarcinoma metastatic to the liver or other organs
Nonpapillary malignant ascites (adenocarcinoma)
Multiple cerebral metastases (adenocarcinoma or squamous carcinoma)
Several lung or pleural metastases (adenocarcinoma)
Multiple metastatic lytic bone disease (adenocarcinoma)
Squamous cell carcinoma of the abdominopelvic cavity

From Pavlidis N, Pentheroudakis G: Cancer of unknown primary site, *Lancet* 379:1428-1435, 2012.

BASIC INFORMATION

DEFINITION

Infection caused by the species of the genus *Candida.* All the different *Candida* species can cause disease, but infections caused by *Candida albicans* are the most common. *Candida* species are ubiquitous and are the most common fungal pathogens affecting mankind. Cutaneous candidiasis comprises superficial *Candida* infections of the skin and mucosal membranes.

Cutaneous candidiasis can be classified into two subgroups: Cutaneous candidiasis syndromes and chronic mucocutaneous syndromes. Cutaneous candidiasis syndromes include:

- Generalized cutaneous candidiasis
- Intertrigo
- *Candida* folliculitis
- Paronychia/onychomycosis
- Perianal candidiasis
- Erosio interdigitalis blastomycetica
- Balanitis

Chronic mucocutaneous syndromes include:

- Oropharyngeal candidiasis
- Esophageal candidiasis
- Vulvovaginal candidiasis
- GI candidiasis (gastric/intestines/perianal)
- *Candida* cystitis

SYNONYMS

Yeast infection
Candidosis
Moniliasis
Oidiomycosis

ICD-10CM CODES	
B37.2	Candidiasis of skin and nail
B37.8	Candidiasis, unspecified
B37.89	Other sites of candidiasis

EPIDEMIOLOGY & DEMOGRAPHICS

- *Candida* species: It is the most common fungal infection in immunocompromised people.
- Most females (75%) experience an episode of vulvovaginal candidiasis in their lifetime.

INCIDENCE: Estimated to be 50 cases per 100,000 persons

PREVALENCE: Colonizes more than 50% of U.S. population

PREDOMINANT SEX AND AGE:

- Female > male
- No predominant age, but neonates and the elderly (adults >65 yr) are susceptible to *Candida* colonization and to getting mucocutaneous candidiasis

RISK FACTORS: Risk factors that allow *Candida* infection include:

- Age >65 yr
- Females in the third trimester
- Defects in the mucocutaneous barrier (e.g., wounds, burns, ulcerations)
- Decreased/defective granulocytes/monocytes
- Diseases of white blood cells (e.g., chronic granulomatous disease)
- Complement deficiency
- Certain diseases associated with cell-mediated immunity (e.g., HIV, DM)
- Use of certain medications (e.g., broad-spectrum antibiotics, high doses of corticosteroids)
- Increased skin pH due to panty liners and occlusive attire
- Chronic mucocutaneous candidiasis: (CMC) is characterized by susceptibility to *Candida* infection of skin, nails (Fig. E1), and mucous membranes. Patients with recessive CMC and autoimmunity have mutations in the autoimmune regulator *AIRE.* Mutations in the CC domain of *STAT1* underlie autosomal-dominant CMC and lead to defective Th1 and Th17 responses, which may explain the increased susceptibility to fungal infections (van de Veerdonk et al). Some patients have autosomal recessive polyglandular autoimmune syndrome type 1 (also autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy [APECED] syndrome)

Anatomical sites predisposed to *Candida* infection include:

- Axilla
- Beneath the breast, abdominal fold, intertriginous areas
- Periungual creases
- Inguinal creases
- Back and buttocks of bedridden persons

PHYSICAL FINDINGS & CLINICAL PRESENTATION

There are several clinical presentations of cutaneous candidiasis. A few are presented here.

- Cutaneous candidiasis
  1. Presents as erythematous, sometimes shiny with flakes and fluid lesions at the edge of the redness (satellite pustules). It is itchy, and the skin becomes inflamed. Pustules may be present in candidiasis of the scrotal and perineal skin
- Gastrointestinal tract candidiasis
  1. Oropharyngeal candidiasis [thrush]
     a. Usually seen in diabetics, after exposure to inhaled steroids, broad-spectrum antibiotics, chemotherapy, radiation to head and neck, and in immunosuppressed individuals (e.g., patients with a history of HIV infection). It is also seen in some patients who wear dentures
        Symptoms include:
        (1) White, thick patches on the oral mucosa (Fig. E2), tongue, palate, or oropharynx or under dentures
        (2) Dysphagia, mouth soreness, and pain on eating and swallowing
        (3) Tongue burning
     b. Physical examination shows:
        (1) Erythema of the buccal mucosa
        (2) White patches on buccal cavity surfaces (described previously)
        (3) Transverse fissuring
  2. Esophageal candidiasis:
     a. Most common in patients with:
        (1) Hematologic cancers
        (2) HIV/AIDS
     b. History of oropharyngeal candidiasis. Symptoms include:
        (1) Odynophagia (pain on swallowing), hallmark of the disease
        (2) Dysphagia
        (3) Epigastric pain
        (4) Retrosternal pain
     c. Physical examination shows:
        (1) Affects mainly the distal one third of the esophagus. Endoscopy shows areas of the erythema and edema; scattered white patches or ulcers
  3. Perianal candidiasis:
     a. Skin maceration
     b. Itching
     c. Frequently extends to the perineum
- Paronychia/onychomycosis
  1. Fungal infection of the nail and surrounding tissues
  2. Associated with diabetes mellitus and immersion of hands or feet in water
  3. History: Pain and redness around and beneath the nail and nail bed
  4. Physical exam: Inflammation around the toe nail. There may also be nail thickening and discoloration (dystrophic nails). Nail loss may also occur
- Respiratory tract candidiasis
  1. Usually seen in hospitalized patients
  2. About 25% of outpatients have their respiratory tract colonized by *Candida* species
- Genitourinary tract candidiasis
  1. Vulvovaginal candidiasis
     a. Most common form of mucosal candidiasis.
     b. Risk factors include increased estrogen level (e.g., contraceptive pill), steroid or antibiotic use, diabetes, HIV infection, IUD, and diaphragm use.
     c. It causes itching, curdy white discharge, and occasionally dysuria, dyspareunia, and vaginal irritation.
     d. On examination the mucosa may be inflamed with vulvar and vaginal erythema, and vaginal discharge, classically described as white and curdy.
     e. Painful erythema or itchy penile inflammation may occur in male sexual partners of affected females.
  2. *Candida* balanitis
     a. Usually acquired through sexual contact with a partner who has vulvovaginal candidiasis. Common in diabetic patients and uncircumcised individuals. The dominant species is *C. albicans.*
     b. Symptoms include penile pruritus and white patches on penis. There could be severe burning and itching. Infection could also spread to the perineum.
     c. Physical exam: Dry, erythematous, and scaly patches on penis and sometimes on the thighs, scrotum, and buttocks. Papules, vesicles or pustules and ulceration may also be present.

- **Others**
  1. Erosio interdigitalis blastomycetica: Denudating/macerating area commonly seen in third web space.
  2. Mastitis: Injured nipples in lactating women can lead to infections, including *Candida* infections.
  3. *Candida* folliculitis: Pustulous nodules in hairy areas.
  4. Intertrigo: This occurs in folds of the skin and creases (Fig. E3). It is characterized by erosions, exudation, oozing, and maceration.

ETIOLOGY

The most common cause of cutaneous candidiasis is *Candida albicans.*

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Intertrigo
Seborrheic dermatitis
Psoriasis
Bacterial vaginosis
Contact dermatitis

WORKUP

- Mucocutaneous and cutaneous candidiasis
  1. Obtain scrapings from the skin, oral, and vaginal mucosa or nails.
  2. The presence of hyphae/pseudohyphae or budding yeast cells on wet smear, as well as confirmation by culture, is the recommended procedure to diagnose cutaneous candidiasis.
  3. KOH smears are helpful.
- Respiratory candidiasis
  1. Sputum gram stain: Shows yeast cells
  2. Sputum cultures
  3. Lung biopsy: Establishes the diagnosis
- Gastrointestinal candidiasis
  1. Upper endoscopy with or without biopsy (Fig. 4)

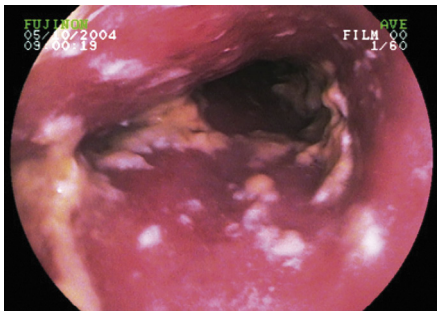

FIG. 4 Endoscopic appearance of esophageal candidiasis. (Courtesy Dr. B. Rembacken, Leeds, U.K.)

Rx TREATMENT

PHARMACOLOGIC THERAPY

- Cutaneous candidiasis
  1. Decrease/prevent moisture in area
  2. Apply antifungal agents (nystatin powder or cream with an azole or ciclopirox [e.g., clotrimazole, econazole, miconazole])
- Gastrointestinal candidiasis
  1. Oropharyngeal candidiasis
     a. Treat with either
        (1) Oral topical antifungal agent (e.g., nystatin 1:100,000 U/ml, 5 ml swish and swallow qid) OR
        (2) Systemic oral azoles (e.g., fluconazole 100 mg qd ×14 days)
  2. In HIV-positive patients, use high doses of fluconazole (100 to 200 mg PO qd for 7 to 14 days), itraconazole, or posaconazole
- *Candida* esophagitis
  1. Treat with systemic fluconazole for 2 to 3 wk
  2. Treat with IV fluconazole if patient is unable to take oral medication
- Genitourinary tract candidiasis
  1. Vulvovaginal candidiasis: Treatment options for acute cases include:
     a. A single dose of oral fluconazole (fluconazole 150 mg PO × 1 dose) OR
     b. Topical antifungal agent
  2. For chronic or recurrent cases, treat with fluconazole 150 mg qd × 3 doses and then 150 mg/wk for 6 mo
- Chronic mucocutaneous candidiasis
  1. Treatment with azoles is effective (e.g., fluconazole 100 to 400 mg daily)
  2. When patient improves, follow with maintenance treatment with same azole for life

FOLLOW-UP CARE

- Mucocutaneous candidiasis
  1. Patient should be instructed to call or follow up if symptoms persist, recur, or worsen.
  2. For recurrent infections:
     a. Check HIV antibodies.
     b. Check FBS, HbA_{1c}.
     c. Rule out hematologic malignancy or solid organ malignancy.
     d. Refer to infectious disease specialist if no etiology is found.

PREVENTION

- Maintaining dry environment (e.g., by wearing cotton underwear)
- Decreased use of antibiotic
- No douching

BASIC INFORMATION

DEFINITION

Severe and invasive diseases are caused by *Candida* infection. More than 15 different *Candida* species cause disease in humans, but at least 95% of invasive disease is caused by *C. albicans, C. glabrata, C. tropicalis, C. parapsilocis,* and *C. krusei*. These organisms cause serious disease referred to as invasive candidiasis. Invasive candidiasis embodies a variety of diseases caused by hematogenous spread of *Candida* to multiple viscera (e.g., kidney, brain, heart). These diseases include candidemia, disseminated candidiasis, meningitis, and endophthalmitis. Invasive candidiasis is a significant cause of morbidity and mortality for certain groups of patients.

SYNONYM

Systemic candidiasis

ICD-10CM CODES	
B37.89	Other sites of candidiasis
B37.1	Pulmonary candidiasis
B37.2	Candidiasis of skin and nail
B37.5	Candidal meningitis
B37.6	Candidal endocarditis
B37.7	Candidal sepsis
B37.9	Candidiasis unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Invasive candidiasis is the most common fungal disease among hospitalized patients in the developed world. It is an important nosocomial infection. It affects over 250,000 people worldwide each yr and causes more than 50,000 deaths.

In the U.S., *Candida* species cause 8% to 10% of nosocomial bloodstream infections (fourth most common bloodstream infection). *C. albicans* is the most common cause of candidemia, but other non-*albicans* species have been implicated in recent yrs. These include *C. glabrata, C. parapsilosis, C. tropicalis,* and *C. krusei.* Incidence rates of candidemia are between 2 and 14 cases/100,000 persons.

PREVALENCE: No data available

PREDOMINANT SEX AND AGE: Equal between males and females; all ages are susceptible.

RISK FACTORS: Prolonged hospitalization and ICU stay, use of broad-spectrum antibiotics, prolonged indwelling of catheters (especially central venous catheters), acute and chronic renal failure, surgery requiring general anesthesia, cancer (e.g., solid neoplasms), transplantation (bone marrow or solid organ), recent chemotherapy/radiation therapy, use of immunosuppressive drugs, parenteral alimentation, use of internal prosthetic devices, organ transplant, hemodialysis, mechanical, surgical procedures

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History
  1. Fever unresponsive to broad-spectrum antibiotics
  2. History of prolonged indwelling IV catheter
  3. A personal history of any of the risk factors listed earlier
- Physical findings (general)
  1. Fever
  2. Hypotension
  3. Generalized malaise
  4. Tachycardia
  5. Change in mental status
  6. Signs of multiorgan system failure
- Specific diseases
  1. Candidemia
     a. A positive blood culture is the gold standard for the diagnosis of candidemia. Obtain blood cultures in patients suspected to have candidemia. *Candida* species must be isolated from at least one blood culture. A positive culture for *Candida* should be investigated thoroughly because of the increased risk of morbidity and mortality. Attributable mortality to candidemia in adults is 15% to 20%.
     b. Most common manifestation of invasive candidiasis.
     c. Physical exam may include fever, macronodular skin lesions, septic shock, *Candida* endophthalmitis.
  2. Disseminated candidiasis
     a. Seen in patients with neutropenia who have undergone cytotoxic chemotherapy for a hematologic malignancy
     b. Associated with multiple deep-organ infections or failure
     c. Blood culture positive
     d. Fever not responding to broad-spectrum antibiotics
     e. Physical exam: Discrete erythematous or palpable rash, sepsis/septic shock
  3. Endophthalmitis
     a. Iatrogenic/accidental or traumatic fungal infection of the eye (exogenous) or hematogenous seeding of the eye (endogenous); *C. albicans* accounts for about 90% of cases of endogenous endophthalmitis
     b. Starts as choroidal lesion, progresses to vitreitis and endophthalmitis and eventually blindness
     c. Physical exam shows fever. An early funduscopic exam by an ophthalmologist should be performed in all patients with candidemia. Funduscopic examination may show large and off-white cotton ball–like lesions with indistinct borders. Patients usually present with decreased visual acuity and occasional pain
  4. *Candida* infection of the CNS
     a. Exogenous and endogenous forms
     b. Usually invades the meninges
     c. Commonly found in long-term ICU patients
     d. May present as meningitis, mycotic aneurysms, change in mental status
     e. Physical examination reveals fever, neck rigidity, confusion, headache, and coma
  5. Candidal musculoskeletal infections
     a. Candida infect the skeletal system, especially the joints as a result of trauma, joint injections, and other surgical interventions, such as IV drug use (hematogenous seeding)
     b. Previously uncommon; now relatively common probably due to increased frequency of candidemia and disseminated candidiasis
     c. Knee and vertebral column (especially lumbosacral vertebral disks and vertebral bodies, which can lead to vertebral osteomyelitis, with or without discitis) are involved
     d. Physical exam is usually unremarkable but may show tenderness over involved area, fever, erythema, bone deformity, weight loss, and sometimes a draining fistulous tract
  6. Candidal infections of the heart
     a. Usually found in patients with artificial heart valves, IV drug users, and patients with an indwelling central venous catheter
     b. May present as infective endocarditis, myocarditis, or pericarditis
     c. Physical examination reveals fever, hypotension, tachycardia, new or changing murmur, and signs and symptoms of heart failure
  7. Hepatosplenic candidiasis (chronic systemic candidiasis)
     a. Seen in patients with hematologic malignancy and neutropenia; usually develops during recovery from a neutropenic state (normally after undergoing myeloablative chemotherapy)
     b. On examination, patients have low-grade fever, right upper quadrant pain, palpable/tender liver, splenomegaly, and rarely jaundice
     c. MRI/CT/US may reveal multiple focal abnormalities in the liver, spleen, and kidneys
  8. *Candida* peritonitis
     a. Associated with GI surgery: Perforations, acute necrotizing pancreatitis, peritoneal dialysis
     b. Clinical manifestations include fever, chills, abdominal pain; nausea, vomiting, constipation
     c. Physical examination reveals abdominal distention, abdominal pain, absent bowel sounds
  9. Other forms of invasive candidiasis
     a. *Candida* splenic abscess
     b. *Candida* cholecystitis
     c. Renal candidiasis
     d. Mediastinitis
     e. Empyema
     f. Pneumonia (rare)
     g. Meningitis
     h. Septic arthritis

ETIOLOGY

- Several species of *Candida* exist in nature
- Medically significant include:
  1. *C. albicans:* Together with *C. glabrata,* they account for 70% to 80% of *Candida* in invasive candidiasis.
  2. *C. glabrata:* Together with *C. albicans,* they account for 70% to 80% of *Candida* in invasive candidiasis.

3. *C. parapsilosis:* Associated with indwelling vascular catheters and prosthetic devices
4. *C. tropicalis:* Especially in leukemic patients
5. *C. krusei:* Resistant to fluconazole and ketoconazole

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sepsis (bacterial)
- Septic shock
- Cryptococcosis
- Aspergillosis

LABORATORY TESTS

- Laboratory studies are nonspecific. It is often necessary to perform several diagnostic tests to achieve maximum accuracy.
- High index of suspicion is needed.
- Candidemia/disseminated candidiasis: Candidemia represents the tip of the iceberg with respect to the more invasive forms of candidiasis. Central lines often contribute to the propagation of candidemia. From the blood, infection can spread to almost any organ.
  1. Blood culture is the gold standard of diagnosis. They are helpful but have low positive yield. Only 40% to 60% of patients with infection have positive culture. 95% of blood cultures that are positive for *Candida* species become positive within 96 hours. Candida in a blood culture is NOT a contamination, and the source of the infection should be sought.
  2. Diagnosis can also be made from normally sterile sites. Specific species identification is necessary since only 10% of known *Candida* species produce disease in humans.
  3. The T2 magnetic resonance assay of whole blood can be performed on blood samples even after initiation of antifungal therapy.
  4. Serum (1,3) beta-D-glucan detection assay: High specificity and high positive predictive value. It can also be used for diagnosing invasive candidiasis when blood cultures are negative.
  5. New techniques allow for quick identification of *Candida* species in blood. These include:
     a. Peptide nucleic acid fluorescence in-situ hybridization (PAN-FISH)
     b. Matrix-assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS)
- Hepatosplenic candidiasis (focal):
  1. Elevated serum alkaline phosphatase.

IMAGING STUDIES

- Imaging studies are generally not required or useful.
- Ultrasound is useful for diagnosing hepatosplenic abscess. "Bull's eye or target lesions" are observed in the liver and spleen.
- CT scanning may be used to diagnose hepatosplenic candidiasis, as well as intraabdominal/renal abscesses.
- ECHO is useful to rule in or rule out *Candida* endocarditis.

Rx TREATMENT

- To successfully treat invasive *Candida* infection, it is important to start antifungal medication as early as possible. A small delay (approximately 12 to 24 hr) in starting treatment may result in a significantly excessive mortality rate.
  1. Do not dismiss *Candida* spp. as a contaminant when it is isolated in blood cultures or other sterile sites.
  2. Before treatment, also consider removal of an intravenous catheter.
- Antifungals available include:
  1. Azoles (e.g., fluconazole, posaconazole, itraconazole, voriconazole). They inhibit the synthesis of ergosterol, a fungal cell component.
  2. Echinocandins (e.g., caspofungin, micafungin, anidulafungin). These are glucan synthesis inhibitors. Glucan is an important component of fungal cell walls. Most studies have provided reasonable support for echinocandins as treatment of choice for the majority of patients with invasive candidiasis.
  3. Polyenes (e.g., amphotericin B, lipid formulation of amphotericin, nystatin). Broad spectrum. Their mechanism of action is to increase cytoplasmic permeability.
  4. Antimetabolites (e.g., flucytosine). Flucytosine is deaminated to 5-fluorouracil in fungal cell. 5-Fluorouracil inhibits RNA and protein synthesis.

TREATMENT PLANS

CANDIDEMIA: General principles:

- For documented candidemia, 2 weeks of antifungal treatment after the first negative blood culture is recommended.
- In nonneutropenic patients, a dilated funduscopic examination in the first week of treatment is recommended.
- In neutropenic patients, delay (b) above until neutrophil recovery because characteristic ocular findings may be delayed.
- Treatment depends on whether the patient is neutropenic or not.
  1. **Nonneutropenic adult patients:** The initial treatment is with an Echinocandin, e.g., caspofungin 70 mg loading dose, then 50 mg IV daily *or* micafungin 100 mg IV daily. Alternatives include fluconazole 800 mg as loading dose, then 400 mg/day for at least 2 wk after clinical improvement or negative blood culture. Amphotericin B is equally efficacious.
  2. **Neutropenic adult patients:** An echinocandin is the drug of choice (e.g., caspofungin) 70 mg IV loading dose then 50 mg/day IV or micafungin 100 mg/day IV or anidulafungin 200 mg IV loading dose then 100 mg IV all for at least 2 wk after clear blood culture and after clinical improvement. An alternative is fluconazole.
  3. **Preferred oral step-down therapy:** Neutropenic and nonneutropenic clinically stable patients who have
     a. *Candida*-susceptible fluconazole
     and
     b. Negative blood cultures can be transitioned to oral fluconazole (400 mg [6 mg/kg] daily) after about 5 to 7 days.

DISSEMINATED CANDIDIASIS: Fluconazole is the drug of choice.

DISSEMINATED CANDIDIASIS WITH END-ORGAN INFECTION:

- Treatment is the same as for candidemia of nonneutropenic patients. In most cases, therapy is prolonged for at least 4 to 6 wk.
- The echinocandins are the first-line therapy.

OSTEOMYELITIS OR SEPTIC ARTHRITIS:

- Fluconazole 400 mg IV or PO *or*
- Caspofungin 50 mg IV daily *or*
- Micafungin 100 mg IV daily

ENDOCARDITIS:

- Caspofungin 50 to 150 mg/day *or*
- Micafungin 100 to 150 mg/day *or*
- Anidulafungin 100 to 200 mg/day

MYOCARDITIS:

- Lipid-based amphotericin B 3 to 5 mg/kg daily *or*
- Caspofungin 150 mg/d *or* micafungin 100 mg/d.

ESOPHAGITIS:

- Caspofungin 50 mg IV daily
- Fluconazole 200 to 400 mg/day

PERICARDITIS: Lipid-based amphotericin B 3 to 5 mg/kg daily

SURGICAL CARE: Includes:

- Drainage
- Removal of any foreign bodies
- Surgical debridement
- Organ-specific care (e.g., valve replacement for endocarditis, splenectomy for splenic abscess, or vitrectomy for fungal endophthalmitis)

DISPOSITION

- Several factors affect prognosis: Infection site, degree of immune suppression, and how quickly diagnosis and therapy are initiated
- Overall mortality rate: 30% to 40%

REFERRAL

- Always involve an infectious disease specialist.
- Referral to specialist will depend on the organ involved. For example:
  1. Endocarditis will require a cardiothoracic surgeon.
  2. Endophthalmitis will require an ophthalmologist.

FOLLOW-UP CARE

- Prolonged periods, mainly in the hospital, of antifungal treatment may be necessary.
- Closely monitor patients on amphotericin B because of the high incidence of side effects. Check basic metabolic panel, magnesium, and CBC at least twice a week.

PEARLS & CONSIDERATIONS

PREVENTION

Basic preventive measures are similar to those used for nosocomial infections. This includes:

- Maximizing hand hygiene recommendations:
  1. Hand washing.
  2. Using alcohol/chlorhexidine solution.
- Adhering strictly to recommendations for placement and care of central lines and catheters.
- Judicious use of antimicrobials
  1. Notes on *C. auris*:
     a. CDC issued warnings in 2016 about the emergence of *C. auris*, a multidrug-resistant *Candida* species. It is resistant to fluconazole and amphotericin B in 93% and 35% of patients, respectively.
     b. It has caused invasive health care–associated infections in many countries and has high mortality rates.
     c. Initial treatment is with echinocandin. Patient should be closely followed with cultures.
     d. Special infection control precautions should be followed for patients infected with or colonized by *C. auris.*

PROPHYLAXIS

Antifungal prophylaxis should be limited to patients in whom it has proved beneficial: patients with gastrointestinal anastomotic leakage, patients undergoing transplantation of the pancreas or small bowel, selected patients undergoing liver transplantation who are at high risk for candidiasis, and extremely low-birth-weight neonates in settings with a high incidence of neonatal candidiasis.

PATIENT/FAMILY EDUCATION

- Inform them about the risk factors for invasive candidiasis.
- Inform them of the seriousness of the disease and the associated high morbidity/mortality rates, thus requiring aggressive treatment.
- Side effects and toxicities associated with treatment.

Carbon Monoxide Poisoning PTG

BASIC INFORMATION

DEFINITION

Carbon monoxide (CO) is a colorless, odorless, tasteless, nonirritating gas. When inhaled, it produces toxicity by causing cellular hypoxia and damage.

ICD-10CM CODES

T68	Toxic effect of carbon monoxide
T58.01	Toxic effect of carbon monoxide from motor vehicle exhaust, accidental (unintentional), initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

- A leading cause of accidental and intentional poisoning in the U.S.
- Can occur because of acute toxicity or chronic exposure.
- CO poisoning is seen more frequently during the fall and winter months in cold climates. Frequently seen after storm-related power outages, mostly due to the use of portable gasoline-powered electrical generators.
- Most fatal cases of CO poisoning occur in the home.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Depends on the severity and duration of exposure. The brain and heart are most sensitive to CO poisoning. Table 1 summarizes carboxyhemoglobin concentration and related symptoms.
- Presentation is often nonspecific and may be mistaken for a flulike illness.
- Severity of poisoning does not correlate with carboxyhemoglobin (COHb) levels.
- Mild to moderate poisoning may present with headache, malaise, dizziness, nausea, dyspnea, difficulty concentrating, confusion, and blurred vision. Patients may have tachypnea and tachycardia.
- Severe poisoning may present with hypotension, arrhythmias, myocardial ischemia, pulmonary edema, lethargy, ataxia, loss of consciousness, seizure, coma, or, rarely, cherry-red skin.
- Delayed neurologic sequelae may develop days to weeks after apparent recovery from acute poisoning. Patients may present with neurologic or psychiatric symptoms (cognitive deficits, memory loss, personality changes, movement disorders, Parkinson, psychosis, neurologic deficits).

ETIOLOGY

- CO results from the incomplete combustion of carbon-containing compounds. CO poisoning occurs from inhaling smoke from fires, motor vehicle/motor boat exhaust, or the burning of fuel (oil, wood, coal, gasoline, natural gas) in poorly functioning or improperly ventilated devices (heating systems, stoves/grills, portable generators, etc.). Methylene chloride (paint stripper) fumes are converted to CO by the liver.
- CO toxicity results from tissue hypoxia and direct CO-mediated damage at the cellular level. This may explain why COHb levels alone are not predictive of clinical toxicity. The mechanisms of CO toxicity are not completely understood.
- CO impairs oxygen delivery. CO reversibly binds hemoglobin with an affinity 250 times greater than oxygen, displacing oxygen from hemoglobin and decreasing the oxygen-carrying capacity of blood. By binding to hemoglobin, CO changes the structure of the hemoglobin molecule and decreases oxygen release to tissue.
- CO may also interfere with peripheral oxygen utilization by binding to other heme-containing proteins including cytochromes and myoglobin. Cellular respiration may be depressed by inhibition of mitochondrial function.
- Neurologic toxicity is not explained by hypoxia alone and is related to the complex intracellular actions of CO. CO precipitates an inflammatory cascade that results in oxidative damage and brain lipid peroxidation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral syndromes
- Cyanide, hydrogen sulfide
- Methemoglobinemia
- Amphetamines and derivatives
- Cocaine, phencyclidine (PCP)
- Cyclic antidepressants
- Phenothiazines
- Theophylline

WORKUP

History (duration and source of CO exposure, loss of consciousness), physical examination (detailed neurologic examination), laboratory and imaging tests

LABORATORY TESTS

- COHb level (measured by CO-oximetry on arterial or venous blood). COHb level >3% in nonsmokers confirms exposure. Heavy smokers may have baseline levels up to 10% to 15%. Levels may be low if the patient has already received supplemental oxygen or if delays occur between exposure and testing.
- NOTE: Pulse oximetry and arterial blood gas (ABG) may be falsely normal because neither measures oxygen saturation of hemoglobin directly. Pulse oximetry is inaccurate because of the similar absorption characteristics of oxyhemoglobin and COHb. An ABG is inaccurate because it measures oxygen dissolved in plasma (which is not affected by CO) and then calculates oxygen saturation of hemoglobin.
- Electrolytes, glucose, BUN, creatinine, cardiac biomarkers, ABG (lactic acidosis and rhabdomyolysis may develop), CBC (polycythemia from hypoxia in chronic CO poisoning).
- ECG (ischemia, arrhythmia).
- Pregnancy test (fetus at high risk).
- Consider toxicology screen.
- Table 2 summarizes treatment strategies for acute smoke inhalation.

IMAGING STUDIES

- Chest x-ray (noncardiogenic edema)
- Brain CT, MRI if neurologic abnormalities are present, to exclude other causes

TREATMENT

ACUTE GENERAL Rx

- Remove from site of CO exposure
- Ensure adequate airway
- Continuous ECG monitor
- Fetal monitoring if pregnant
- 100% oxygen by nonrebreather mask or endotracheal tube (decreases half-life of COHb from 4 to 6 hr to 60 to 90 min) until COHb level is <5% and patient is asymptomatic. Table 3 describes the half-life of COHb
- Hyperbaric oxygen (2.5 to 3 atm)
  1. Questionable beneficial effect over normobaric oxygen. Disparate findings in various studies: Some suggest hyperbaric oxygen treatment reduces the incidence of neurologic sequelae, and others have found it worsens neurologic outcomes compared to normobaric oxygen treatment. A large retrospective study suggests it may decrease short-term

TABLE 1 Carboxyhemoglobin Concentration and Related Symptoms

COHb (%)	Symptoms
<20	Slight headache and dilation of peripheral blood vessels
21-40	Severe headache and pulsating in temporal blood vessels, vertigo, dizziness, nausea and vomiting, circulatory collapse
41-60	Symptoms as above, syncope, tachycardia, hyperventilation, intermittent seizures, cyanosis, coma, shock, Cheyne-Stokes respiration
61-80	Coma, intermittent seizures, impaired heart and lung function, weak pulses, slow breathing, death within hours
>81	Death occurs within minutes

COHb, Carboxyhemoglobin.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

TABLE 2 Treatment Strategies for Acute Smoke Inhalation

Current	Under Investigation
Rescue victim from source	Activated protein C
High-flow 100% O_2	Antiinflammatory drugs: • Methylprednisolone • Phenytoin
Body check	Nitric oxide synthase inhibitors
Intravenous access	Antioxidants: • Gamma-tocopherol • 21-aminosteroid
± Intubation	Endothelin-I-receptor antagonist tezosentan
If upper airway edema: • Nebulized adrenaline • Nebulized corticosteroids	P-selectin blockade
If bronchospasm: • Nebulized alpha$_2$-agonists	Nebulized deferoxamine-pentastarch complex
If elevated COHb: • High-flow 100% O_2 • Hyperbaric oxygen	Mechanical ventilation: • High-frequency percussive ventilation • Airway pressure release ventilation • Volumetric diffuse ventilator
If cyanide intoxication: • Amyl nitrate • Sodium thiosulfate • Hydroxocobalamin (Cyanokit)	Extracorporeal membrane oxygenation
Mechanical ventilation, Low tidal volume	Arteriovenous carbon dioxide removal
Nebulized heparin	Pulmonary decontamination with nebulized amphoteric chelating agents
Nebulized *N*-acetylcysteine	

COHb, Carboxyhemoglobin.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult*, ed 4, Philadelphia, 2014, Elsevier.

TABLE 3 Half-Life of COHb

Oxygen Concentration	Half-Life
21% (room air)	4-5 hr
100% (mask or endotracheal)	60-90 min
100% (hyperbaric molecular oxygen)	20-30 min

COHb, Carboxyhemoglobin.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, Saunders.

and long-term mortality, especially in individuals <20 yr old and those with acute respiratory failure. Multiple sessions were associated with lower mortality than a single session
2. Decreases half-life of COHb to 20 to 30 min; increases amount of oxygen dissolved in plasma. It also reduces CO binding to other heme-containing proteins
3. Consider for:
   a. Severe intoxication (COHb >25%, history of loss of consciousness, neurologic symptoms or signs, cardiovascular compromise, severe metabolic acidosis)
   b. Pregnant women with COHb >20% or signs of fetal distress. CO elimination is slower in fetus than mother, fetal Hgb has greater affinity for CO than adult Hgb
   c. Should be instituted quickly if deemed necessary
- Consider concomitant poisoning with other toxic/irritant gases that may be present in smoke (e.g., cyanide) or thermal injury to airway. Toxic effects of CO and cyanide are synergistic
- Identify source of exposure and determine if poisoning was accidental

DISPOSITION

- Patients with mild accidental poisoning can be treated in an ambulatory setting. Those with moderate/severe poisoning or coexisting illness require hospitalization.
- About 35% of patients with moderate to severe poisoning have cardiac dysfunction (arrhythmia, LV systolic dysfunction, ischemia).
- Survivors of severe poisoning are at 14% to 40% risk for neurologic sequelae.
  1. Deficits are usually apparent within 3 wk of poisoning but may present months later.
  2. Risk of developing sequelae is greater if patient lost consciousness during acute poisoning and with older age.
  3. Brain MRI and functional CT may reveal changes; damage is seen most often in the globus pallidus and deep white matter.
  4. Recovery may occur over months to years.
- Severe CO poisoning is associated with increased long-term morbidity and mortality.
- High risk of fetal demise.

REFERRAL

- American Association of Poison Control Centers: 1-800-222-1222
- Hyperbaric unit; accredited facilities are listed on the Undersea & Hyperbaric Medical Society website (www.uhms.org)
- Psychiatric evaluation if intentional poisoning

PEARLS & CONSIDERATIONS

- Hookah smoking is increasingly being recognized as a cause of CO poisoning, especially among young adults.
- Severity of poisoning and prognosis do not correlate with COHb levels because hypoxia represents only a component of CO's toxic effect. New therapies to address CO toxicity are being proposed.
- Neuropsychometric testing is an objective measure of cognitive function but is not universally used.
- Imaging techniques and biomarkers to define severity of CO poisoning, early prediction of CNS damage and prognosis are being studied, but are not ready for application.
- Pulse CO-oximetry measurement of CO saturation has limited clinical use.
- Treatment with hydroxocobalamin (for cyanide toxicity) may make subsequent COHb testing unreliable.
- Contact local fire department to assess environment and identify source of CO.

Carcinoid Syndrome ALG PTG

BASIC INFORMATION

DEFINITION

Carcinoid syndrome is a symptom complex characterized by paroxysmal vasomotor disturbances, diarrhea, and bronchospasm. It is caused by the action of amines and peptides (serotonin, bradykinin, histamine) produced by tumors arising from neuroendocrine cells.

SYNONYMS

Flush syndrome
Argentaffinoma syndrome

ICD-10CM CODE
E34.0 Carcinoid syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Carcinoid tumors are found incidentally in 0.5% to 0.75% of autopsies.
- Carcinoid tumors are principally found in the following organs: Appendix (40%); small bowel (20%; 15% in the ileum); rectum (15%); bronchi (12%); esophagus, stomach, and colon (10%); and ovary, biliary tract, and pancreas (3%). Table E1 summarizes the relative frequencies of selected carcinoid tumors and their prevalence of metastases and carcinoid syndrome.
- The incidence of carcinoids is 2.47 to 4.48/100,000, depending on race and sex, and is highest in black men. The overall incidence has increased over the last 30 yr due in part to improved diagnostic modalities.
- Carcinoid tumors can be classified using the WHO classification as follows:
  1. WHO I: Well-differentiated, <2 cm diameter, low proliferation index (<2%), confined to mucosa and submucosa.
  2. WHO II: Differentiated, >2 cm diameter, invasive growth, high proliferation index (2% to 15%).
  3. WHO III: Poorly differentiated carcinomas with metastases and proliferation index >15%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cutaneous flushing (75% to 90%):
  1. The patient usually has red-purple flushes starting in the face, then spreading to the neck and upper trunk (Fig. E1).
  2. The flushing episodes last from a few minutes to hours (longer-lasting flushes may be associated with bronchial carcinoids).
  3. Flushing may be triggered by emotion, alcohol, or foods or may occur spontaneously.
  4. Dizziness, tachycardia, and hypotension may be associated with the cutaneous flushing.
- Diarrhea (>70%): Often associated with abdominal bloating and audible peristaltic rushes.
- Intermittent bronchospasm (25%): Characterized by severe dyspnea and wheezing.
- Facial telangiectasia.
- Tricuspid insufficiency, pulmonic stenosis from carcinoid heart lesions.

ETIOLOGY

- Carcinoid syndrome is caused by neoplasms originating from neuroendocrine cells.
- Carcinoid tumors do not usually produce the syndrome unless liver metastases are present or the primary tumor does not involve the gastrointestinal tract.

DIAGNOSIS

- See Fig. E2 for diagnostic algorithm.

DIFFERENTIAL DIAGNOSIS

- Flushing: Carcinoid syndrome must be distinguished from idiopathic flushing (IF); patients with IF more often are female, are younger, and have a longer duration of symptoms; palpitations, syncope, and hypotension occur primarily in patients with IF. Additional causes of flushing that need to be ruled out are menopause, medications (niacin, nitrates), alcohol, renal cell carcinoma, medullary cancer of thyroid, VIPoma, mastocytosis, and chronic use of food additives (nitrites, sulfites)
- Diarrhea: irritable bowel syndrome, inflammatory bowel disease, laxative abuse, infectious colitis
- Bronchospasm: Asthma, foreign body, gastroesophageal reflux disease, lung neoplasm

LABORATORY TESTS

- The biochemical marker for carcinoid syndrome is increased 24-hr urinary 5-hydroxyindoleacetic acid, a metabolite of serotonin (5-hydroxytryptamine).
- False elevations can be seen with ingestion of certain foods (bananas, pineapples, eggplant, avocados, walnuts) and certain medications (acetaminophen, caffeine, guaifenesin, reserpine); therefore patients should be on a restricted diet and avoid these medications when the test is ordered.
- Falsely low results can occur with use of alcohol, aspirin, monoamine oxidase inhibitors, and St. John's wort.
- Liver function studies are an unreliable indicator of liver involvement.

IMAGING STUDIES

- CT scan of chest is useful to detect bronchial carcinoids.
- CT scan or MRI of abdomen (Fig. E3) is useful to detect liver metastases (palpable in >50% of cases).
- Iodine-123–labeled somatostatin can detect carcinoid endocrine tumors with somatostatin receptors.
- Scanning with radiolabeled octreotide (Fig. E4) can visualize previously undetected or metastatic lesions.
- Positron emission tomography scan.

TABLE E1 Relative Frequencies of Selected Carcinoid Tumors and Their Prevalence of Metastases and Carcinoid Syndrome

	% of all Carcinoids[a]	% with Metastases	% with Carcinoid Syndrome
Gastric	2-6	22-31	10
Small intestinal[b]	10-28	14-71	3-13
Appendiceal	2-38	2-35	<1
Colonic	4-10	60-71	5
Rectal	10-19	3-14	<1
Pancreatic	<1	66-100	Up to 100
Tracheal/bronchial/pulmonary	85	13	13

[a]Other less-common sites for carcinoids not included here include esophagus, liver, gallbladder, biliary tract, larynx, cervix, ovary, and testis.
[b]Small intestine includes duodenum, ampulla, jejunum, ileum, and Meckel diverticulum.

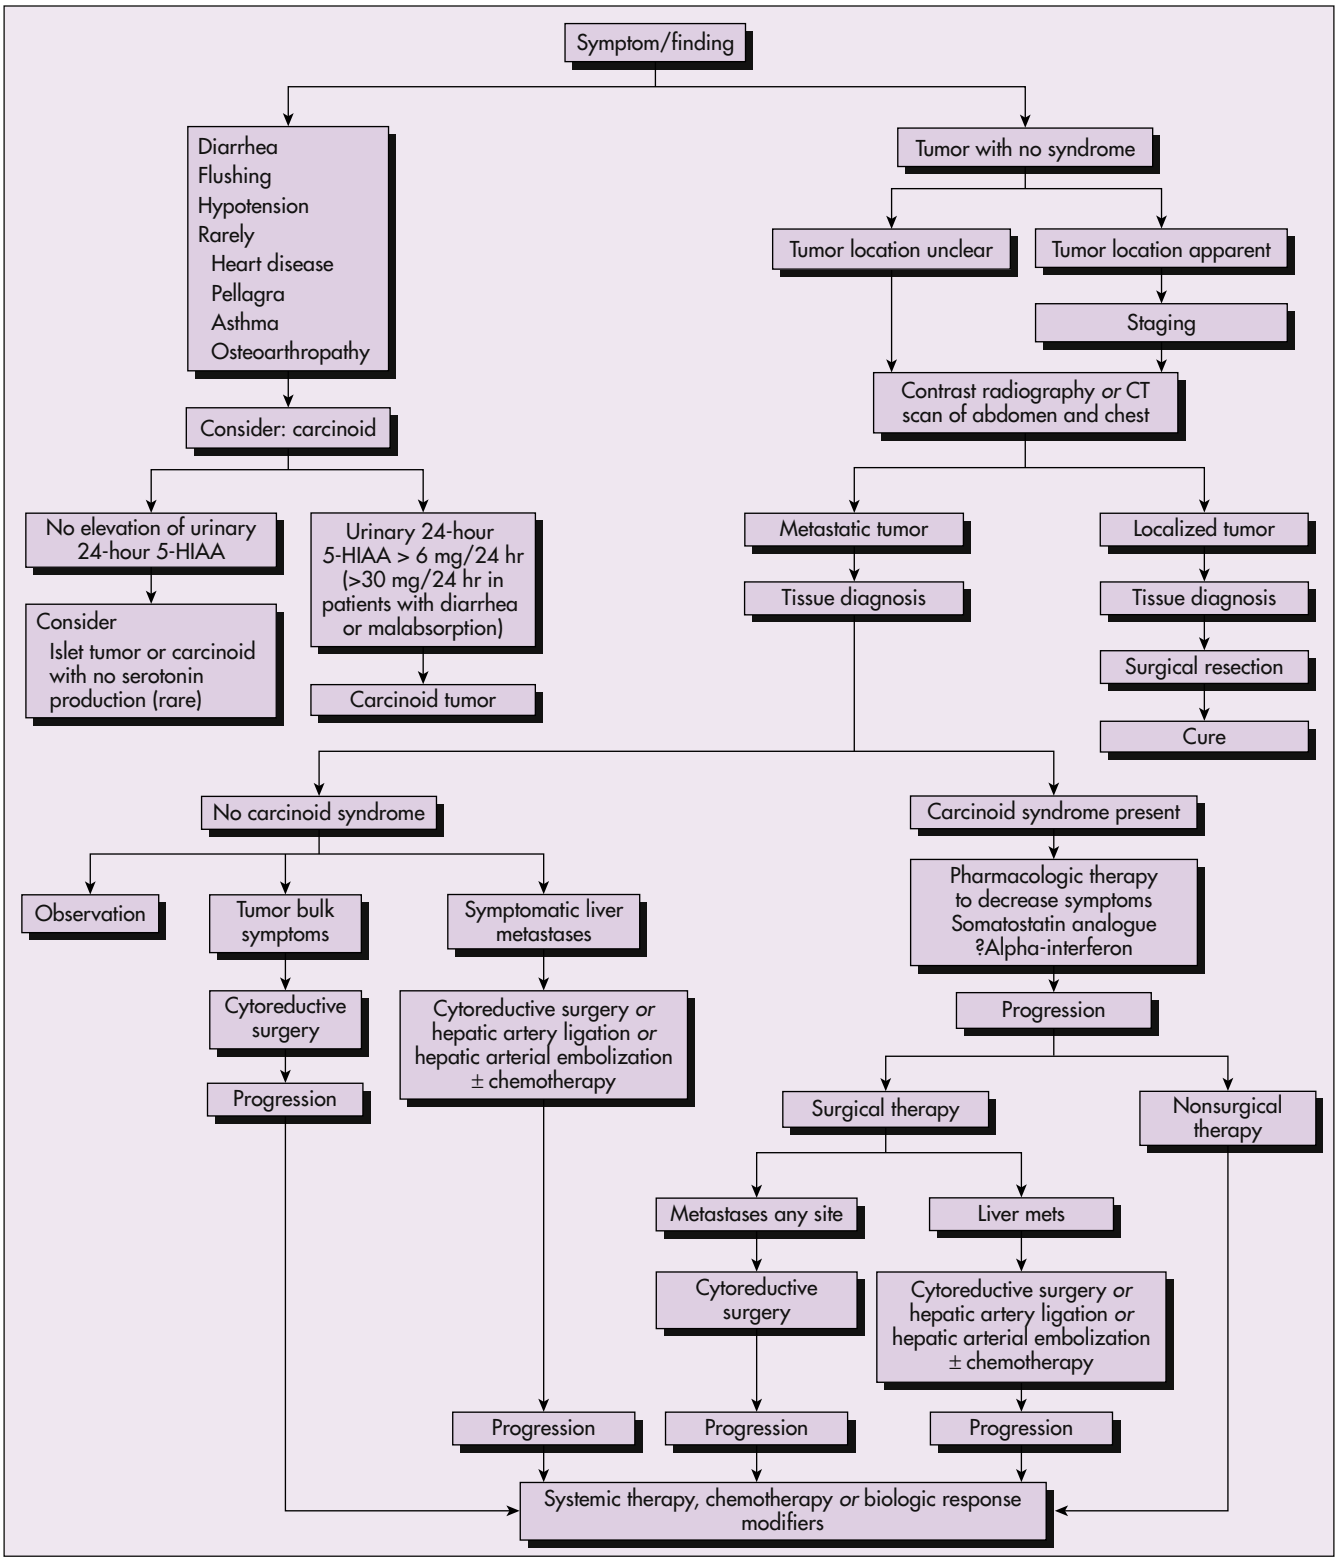

FIG. E2 Algorithm of diagnosis and treatment of carcinoid tumors. *CT,* Computed tomography; *mets,* metastasis. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Avoidance of ethanol ingestion (may precipitate flushing)

GENERAL Rx

- Surgical resection of the tumor can be curative if the tumor is localized or palliative and results in prolonged asymptomatic periods if metastases are present. Surgical manipulation of the tumor can, however, cause severe vasomotor abnormalities and bronchospasm (carcinoid crisis).
- Percutaneous embolization and ligation of the hepatic artery can decrease the bulk of the tumor in the liver and provide palliative treatment of tumors with hepatic metastases.
- Cytotoxic chemotherapy: Combination chemotherapy with 5-fluorouracil and streptozocin can be used in patients with unresectable or recurrent carcinoid tumors; however, it has only limited success. Control of clinical manifestations:
  1. Somatostatin analogues (octreotide and lanreotide) are effective for both flushing and diarrhea in most patients. Telotristat ethyl, a tryptophan hydroxylase inhibitor is FDA approved for use in combination with somatostatin analogues (SSA) for diarrhea inadequately controlled with SSA.
  2. Flushing may be controlled by the combination of H_1- and H_2-receptor antagonists (e.g., diphenhydramine 25 to 50 mg PO q6h and ranitidine 150 mg bid).
  3. Diarrhea may respond to diphenoxylate with atropine (Lomotil).
  4. Bronchospasm can be treated with aminophylline and/or albuterol.
- Nutritional support: Supplemental niacin therapy may be useful to prevent pellagra because the tumor uses dietary tryptophan for serotonin synthesis, resulting in a nutritional deficiency in some patients.
- Interferon alfa may be useful as an additive to control symptoms unresponsive to somatostatin analogues.

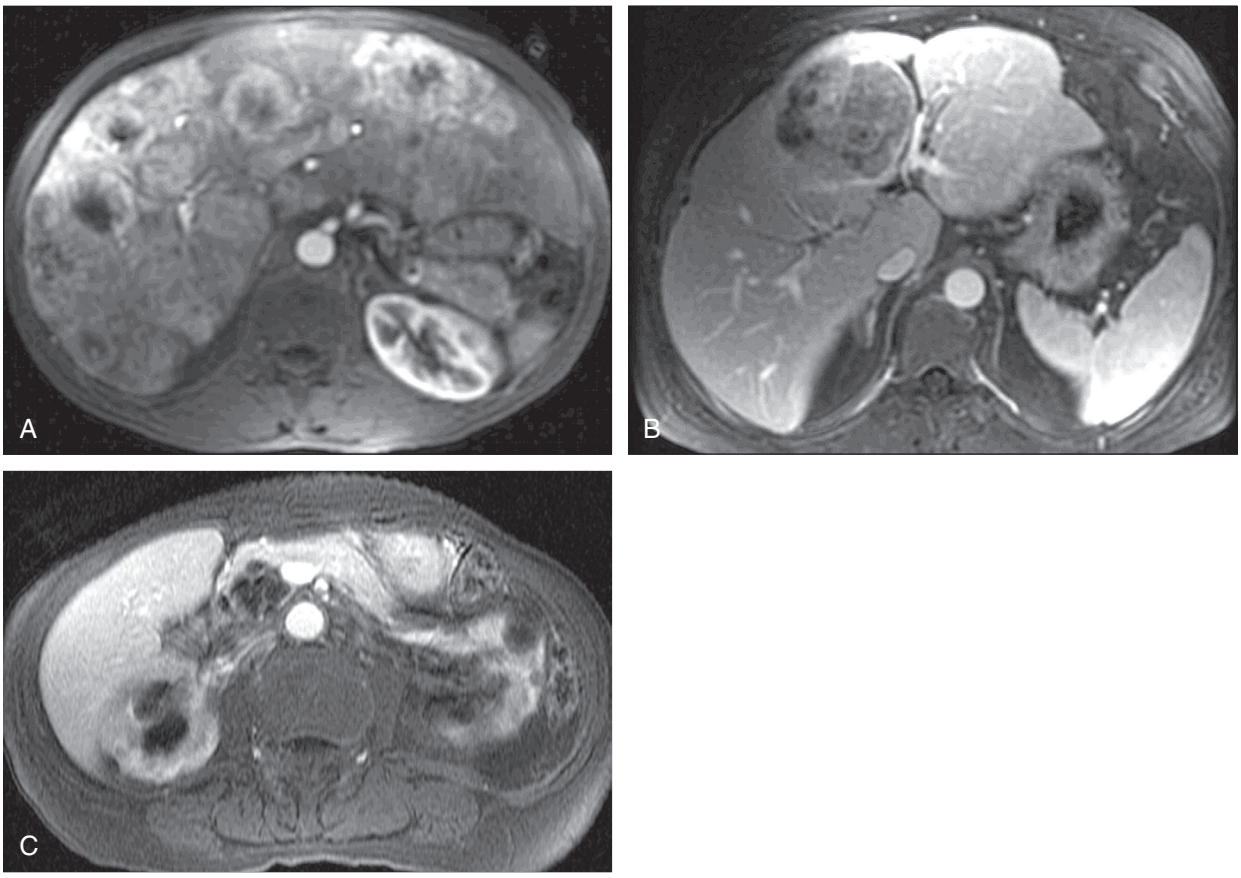

FIG. E4 (A) Carcinoid metastases to the liver. Axial magnetic resonance image with gadolinium shows multiple enhancing masses in both lobes of the liver. **(B)** Hepatoma. Axial magnetic resonance image with gadolinium shows a solid mass in the left lobe of the liver. **(C)** Intraductal papillary mucinous tumor of the pancreas. Axial T1-weighted magnetic resonance image of the abdomen shows a low–signal intensity cystic mass in the head of the pancreas. (Courtesy Dr. Ihab Kamel, The Johns Hopkins University in Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

- Echocardiography and monitoring for right-sided congestive heart failure are recommended for patients with unresectable disease because endocardial fibrosis, involving predominantly the endocardium, chordae, and valves of the right side of the heart, can occur.

DISPOSITION

Carcinoids of the appendix and rectum have a low malignancy potential and rarely produce the clinical syndrome; metastases are also uncommon if the size of the primary lesion is <2 cm in diameter. Table E2 summarizes the 5-yr survival rates of selected carcinoid tumors by stage.

BASIC INFORMATION

DEFINITION

Cardiac tamponade is a life-threatening condition in which an accumulation of fluid within the pericardial space causes impaired diastolic filling and cardiac output as well as arterial hypotension due to elevated pericardial pressure.

ICD-10CM CODE
I31.4 Cardiac tamponade

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Tachypnea/dyspnea
- Chest pain may be present
- Beck triad:
  1. Absolute or relative hypotension
  2. Elevated jugular venous pressure (with prominent *x* descent and blunted *y* descent)
  3. Muffled heart sounds
- Tachycardia (except in uremia or hypothyroid patients)
- Pulsus paradoxus (decrease in systolic arterial pressure of 10 mm Hg or more during normal inspiration while in normal sinus rhythm). Tamponade settings in which pulsus paradoxus may not be present are summarized in Box 1
- Pericardial friction rub may be heard in patients with cardiac tamponade due to inflammatory pericarditis
- Reduced or absent apical cardiac impulse
- Signs of hypoperfusion from reduced cardiac output (diaphoresis, cool extremities, peripheral cyanosis, and depressed sensorium)

ETIOLOGY

- Acute (rapidly accumulating pericardial effusion leading to cardiac tamponade): Does not need a large amount of effusion to cause tamponade; rather, it is the rapidity of fluid accumulation that leads to clinical tamponade. It requires urgent reduction of pericardial pressure. Causes for acute cardiac tamponade include:
  1. Penetrating chest trauma
  2. Aortic dissection (more commonly in Type A)
  3. Postinfarction myocardial rupture and/or hemorrhagic pericarditis (Dressler syndrome)
  4. Iatrogenic (right ventricular perforation during central line and pacemaker insertions, endomyocardial biopsy, cardiac ablation, post–coronary bypass surgery or post–percutaneous coronary intervention)
- Subacute or chronic: Occurs over days to weeks, and the effusion is usually large; causes include the following:
  1. Malignancy (e.g., lung, breast, lymphoma)
  2. Viral pericarditis (e.g., Coxsackie, human immunodeficiency virus, enterovirus, HSV 6, parvovirus, etc.)
  3. Bacterial, fungal, or tuberculous pericarditis
  4. Uremia
  5. Hypothyroidism/myxedema (rare)
  6. Collagen vascular disease (e.g., lupus, rheumatoid arthritis, scleroderma)
  7. Radiation
  8. Post–myocardial infarction or post–cardiac ablation inflammation
  9. Idiopathic
- Regional cardiac tamponade occurs when the localized or loculated hematoma compresses only selected cardiac chambers

BOX 1 Tamponade Settings in Which Pulsus Paradoxus May Not Be Present

- Nonrestrictive (large) atrial septal defect
- Severe aortic insufficiency
- Loculated effusion
- LV hypertrophy and other causes of elevated LV diastolic pressure
- Shock caused by hypovolemia, or profound circulatory collapse with tamponade
- Severe left ventricular dysfunction
- Low-pressure tamponade
- RV hypertrophy or other cause of impaired RV filling
- Positive-pressure ventilation
- Arrhythmias

LV, Left ventricular; *RV,* right ventricular.
From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

DIAGNOSIS

Cardiac tamponade is a clinical diagnosis made at the bedside using patient history and physical examination. The echocardiogram can help confirm or reject the clinical diagnosis. Tamponade can be confirmed invasively by the measurement of elevated intrapericardial pressures with an intrapericardial catheter and right heart catheterization. Typical findings are diastolic equalization of pressures, usually ranging from 10 to 30 mm Hg (diastolic pulmonary artery pressure = right ventricular diastolic pressure = right atrial pressure = intrapericardial pressure), and lowering of the intrapericardial pressure with fluid drainage. Thereafter, the underlying etiology must be determined with specific laboratory work (see "Laboratory Tests").

DIFFERENTIAL DIAGNOSIS

Other conditions that can also lead to elevated jugular venous pressure, decreased systemic pressure, and pulsus paradoxus include:

- Chronic obstructive pulmonary disease and asthma exacerbations
- Constrictive pericarditis (Table 1)
- Effusive-constrictive pericarditis
- Restrictive cardiomyopathy
- Right ventricular infarction
- Pulmonary embolism
- Chronic biventricular heart failure

LABORATORY TESTS

- Electrolytes, blood urea nitrogen, creatinine, erythrocyte sedimentation rate, thyroid function tests, antinuclear antibody, rheumatoid factor, PPD, blood cultures, viral titers, and pericardial fluid analysis including cytology and cultures
- Possible 12-lead ECG findings:
  1. Sinus tachycardia
  2. PR depression and/or diffuse ST elevations if acute pericarditis is present
  3. Electrical alternans (beat to beat alternations in the QRS complex heights) (Fig. E1)
  4. Low QRS voltage in patients with a pericardial effusion may be a specific manifestation of cardiac tamponade, not of the effusion (QRS complex <0.5 mV in the limb leads and <1.0 mV in precordial leads)

IMAGING STUDIES

- Chest radiograph (enlarged cardiac silhouette with clear lung fields) (Fig. 2)
- Chest CT (may overestimate size of the effusion) (Fig. 3)
- Cardiac MRI (as an adjunct to echocardiography)
- Echocardiogram findings (Fig. 4):
  1. Pericardial effusion
  2. Right atrial inversion for greater than one third of systole has a sensitivity of 94% and a specificity of 100% for the diagnosis of tamponade
  3. Diastolic collapse of the right ventricle (early diastole) is pathognomonic and very specific
  4. >25% mitral and >50% tricuspid valve inflow variation on the first beat of inspiration and expiration, respectively
  5. Plethoric inferior vena cava (IVC dilation and <50% decrease in the diameter of the IVC during inspiration)
  6. Left atrial collapse (high specificity)
- Cardiac catheterization as discussed earlier will see equalization of intracardiac diastolic pressures and increase of right-sided pressures and reduction of left-sided pressures, which subsequently causes pulsus paradoxus (the pathognomonic finding on physical examination)

TABLE 1 Hemodynamics in Cardiac Tamponade and Constrictive Pericarditis

	Tamponade	Constriction
Paradoxical pulse	Usually present	Present in ~1/3
Equal left- and right-sided filling pressures	Present	Present
Systemic venous wave morphology	Absent *y* descent	Prominent *y* descent (M or W shape)
Inspiratory change in systemic venous pressure	Decrease (normal)	Increase or no change (Kussmaul sign)
"Square root" sign in ventricular pressure	Absent	Present

From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, WB Saunders.

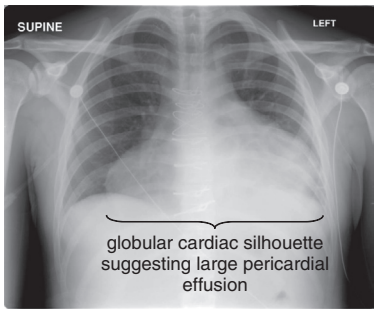

FIG. 2 Massive pericardial effusion and tamponade. This 23-yr-old male has a history of aortic valve replacement for infective endocarditis. He presented with increased chest pain and dyspnea. His chest x-ray shows a globular cardiac silhouette, suggesting a large pericardial effusion. The lung fields and right costophrenic angle appear clear, although the left costophrenic angle is hidden behind the heart and cannot be assessed. The patient underwent chest computed tomography to evaluate his aorta, as he complained of severe interscapular pain as well (see Fig. 3). (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, WB Saunders.)

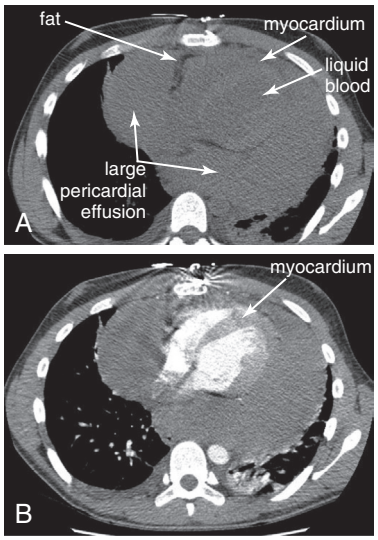

FIG. 3 Massive pericardial effusion. Same patient as Fig. 2. The patient underwent chest computed tomography (CT) without **(A)** and then with **(B)** intravenous contrast to evaluate his aorta, which was normal. However, the CT confirmed a massive pericardial effusion surrounding a normal-appearing heart. Without contrast, note that fluid blood within the chambers of the heart has a slightly lower density than the pericardial effusion, which has a density more similar to that of myocardium. When contrast is administered, the ventricular chambers fill completely, and the myocardium enhances and becomes somewhat brighter than the surrounding pericardial effusion. The heart itself is outlined by a thin stripe of fat, which appears nearly black on soft tissue windows. The patient developed hypotension, suggesting cardiac tamponade, and pericardial window was performed for drainage of the effusion. In the operating room, the effusion was found to be coagulated blood. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, WB Saunders.)

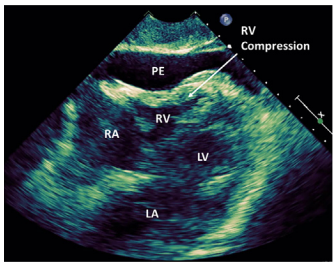

FIG. 4 Cardiac tamponade on echocardiography. Echo shows large pericardial effusion which is compressing the right ventricle. *LA,* Left atrium; *LV,* left ventricle; *PE,* pericardial effusion; *RA,* right atrium; *RV,* right ventricle. (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Cardiac tamponade should be treated emergently with removal of the pericardial fluid (Fig. E5).
- Avoid drugs that reduce preload (e.g., nitrates, diuretics).
- Large pericardial effusions (>20 mm) without hemodynamic compromise (tamponade) can be managed conservatively with careful monitoring, IV fluids, treatment of the underlying cause, clinical follow-up, and frequent serial surveillance echocardiography.

ACUTE GENERAL Rx

- Aggressive intravascular volume expansion (saline or blood)
- Emergency pericardial fluid removal by pericardiocentesis or surgical pericardiotomy by way of the subxiphoid pericardial window
- Pericardiocentesis should be performed under echocardiographic and fluoroscopic guidance when available
- Pericardiocentesis is an absolute contraindication if the etiology of the pericardial effusion is aortic dissection, wherein emergent surgical management is indicated
- Inotropic or vasopressor support if above measures cannot be performed immediately

CHRONIC Rx

- Depends on etiology. Patients with inflammatory causes of pericarditis leading to effusion should be treated with antiinflammatory therapy (NSAIDs) for an extended 3-mo course of colchicine
- Pericardiocentesis with draining catheter: The catheter can be left inside the pericardium to allow continued drainage for 24 to 48 hr. If residual fluid still persists with hemodynamic compromise, surgical drainage should be considered. In the absence of significant residual fluid (output <50 ml in 24-hr period), discontinuation of the draining catheter can be done with periodic postprocedure echocardiographic monitoring for reaccumulation (e.g., 24 hr, 7 days, 30 days, 3 mo, 6 mo, 12 mo) depending on the etiology and the rate of reaccumulation
- Other surgical drainage procedures include:
  1. Subxiphoid pericardiotomy drainage
  2. Pericardial window; draining the pericardial fluid into the left hemithorax
  3. Limited pericardiectomy
  4. Complete pericardiectomy, especially in patients with effusive-constrictive pericarditis, bacterial pericarditis, or tuberculous pericarditis (See "Pearls & Considerations")

DISPOSITION

The prognosis of cardiac tamponade depends on the underlying cause.

REFERRAL

- Emergent cardiology consultation along with thorough echocardiographic exam should be made if cardiac tamponade is suspected.
- Cardiothoracic surgery or interventional cardiology consultation should also be considered if pericardial drainage is indicated.

PEARLS & CONSIDERATIONS

- Cardiac tamponade should always be considered during pulseless electrical activity arrest and may require emergent pericardiocentesis at the bedside.
- Evaluation for pulsus paradoxus should always be performed during normal respiration because deep inspiration may render a false-positive finding.
- Strong consideration should be given to performing early pericardiocentesis in patients who have pericardial effusion associated with bacterial pneumonia or empyema because the incidence of bacterial pericarditis is especially high in this clinical situation and the subsequent development of cardiac tamponade and severe chronic constrictive pericarditis are ominous complications.
- Pericardiocentesis is an absolute contraindication if the etiology of the pericardial effusion is due to aortic dissection extending into the pericardial sac.
- As little as 100 ml of fluid can lead to acute cardiac tamponade if the rate of accumulation is rapid, whereas with gradual accumulation, the pericardial sac can hold up to 5 L of fluid before tamponade occurs.
- With effusions that are small, organized, and/or loculated, needle aspiration should generally be avoided. An exception is acute cardiac tamponade complicating a cardiac procedure (e.g., percutaneous coronary intervention) with anticoagulation. In this setting, the effusion is often small, but pericardial pressure rises very quickly, resulting in hemodynamic compromise.

This finding, particularly in concert with sinus tachycardia and relatively low voltage, is a highly specific, although not sensitive, marker of cardiac tamponade. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right. (From Bonow RO: *Heart disease,* ed 9, Philadelphia, 2012, WB Saunders.)

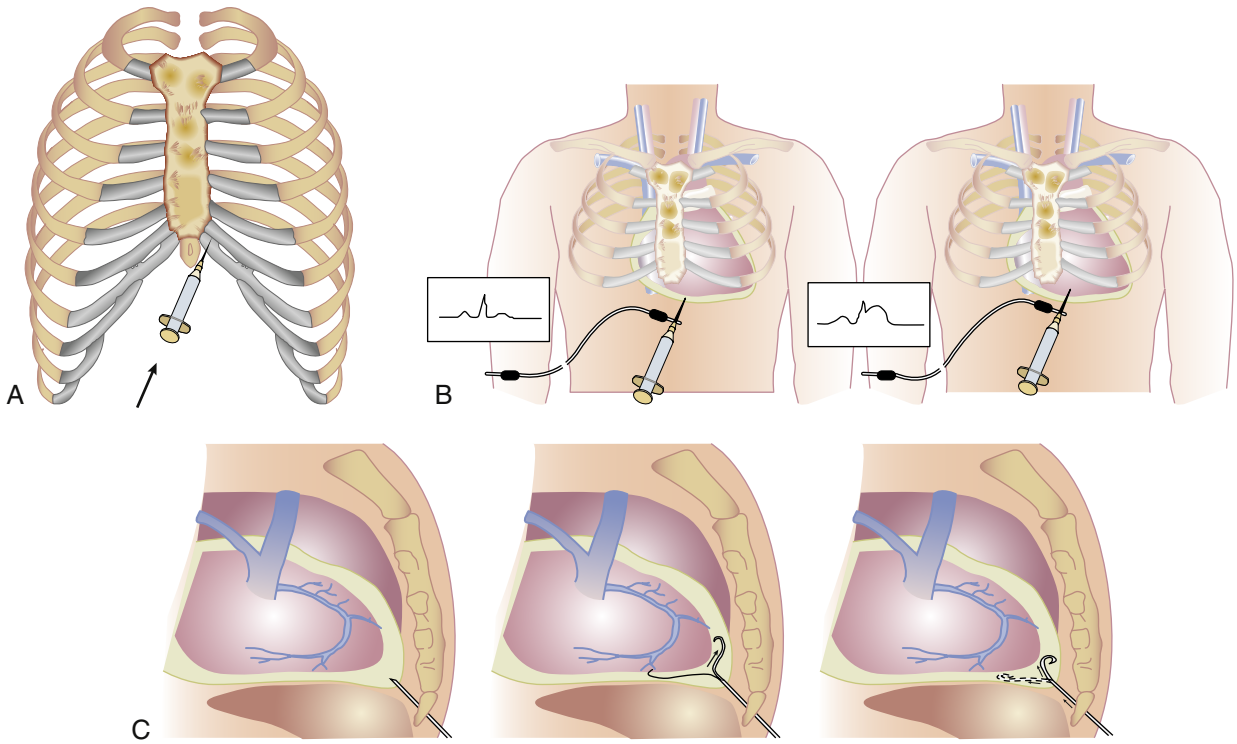

FIG. E5 Diagrammatic representation of a pericardiocentesis procedure via subxiphoid approach. **A,** A subxiphoid approach is used. **B,** A pericardial needle is connected to an electrocardiogram (ECG) lead and is advanced left, lateral to the subxiphoid area, aiming toward the left shoulder. ST-segment elevation is seen on the ECG lead tracing when the needle touches the epicardium. The needle should be retracted slightly until the ST-segment elevation disappears. **C,** After the pericardial space is entered with the pericardial needle, a guidewire is introduced in the pericardial space through the needle. The needle is removed, and a catheter is inserted in the pericardial sac over the guidewire (either anteriorly or inferiorly in the pericardial sac). (From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.)

Cardiomyopathy, Chemical-Induced

BASIC INFORMATION

DEFINITION

Cardiomyopathy, chemical-induced (CMc), is a change in myocardial structure and/or function caused by chemical compounds. Many chemicals, including environmental toxins prescription drugs, and illicit drugs, are associated with cardiomyopathy (CM). These include (but are not limited to) alcohol, cocaine, amphetamines, chloroquine, anabolic steroids, anthracyclines, 5-fluorouracil (5-FU), zidovudine, tyrosine kinase inhibitors, and trastuzumab.

SYNONYMS

Alcoholic cardiomyopathy (ACM)
Cocaine-induced CM
Anabolic steroid-induced CM
Anthracycline-induced CM
Chemotherapy-induced CM
CMc

ICD-10CM CODE
I42.7 Cardiomyopathy due to drug and external agent

EPIDEMIOLOGY & DEMOGRAPHICS

- ACM occurs in about 5% to 10% of alcoholics and accounts for 21% to 36% of dilated cardiomyopathy in high-income countries. Most patients in whom alcoholic cardiomyopathy develops have been drinking more than 80 to 90 g of ethanol per day for more than 5 yr. A key factor for diagnosing ACM is a history of heavy alcohol consumption in the absence of coronary artery disease.
- The risk of doxorubicin-induced cardiotoxicity is dose dependent: 3% to 5% with 400 mg/m^2, 7% to 26% at 550 mg/m^{22}, and 18% to 48% at 700 mg/m^2.
- The addition of trastuzumab to an anthracycline-based chemotherapy regimen markedly increases the incidence of heart failure (28% vs. 1.7% to 21% with trastuzumab alone). The incidence can be significantly reduced by introducing a drug-free interval between the agents. Long-term follow-up data regarding trastuzumab cardiotoxicity are favorable, as the cardiotoxic effects generally manifest during treatment and are reversible.
- Other chemotherapeutic agents known to cause cardiomyopathy include idarubicin (>90 mg/m^2, 5% to 18%), epirubicin (>900 mg/m^2, 0.9% to 11.4%), docetaxel (2.3% to 13%), cyclophosphamide (7% to 28%), bortezomib (2% to 5%), sunitinib (2.7% to 19%), 5-fluorouracil [5-FU] (6% to 7%), and carfilzomib (11% to 25%). Table 1 summarizes chemotherapeutic agents implicated in clinical syndromes of cardiotoxicity.

PREDOMINANT SEX AND AGE: The prevalence of ACM appears to be similar among alcoholic men and women, with women developing left ventricular (LV) dysfunction at a lower ethanol dose than men. Significant racial differences exist, with blacks having higher mortality rates than non-Hispanic whites. Anthracycline- and trastuzumab-induced cardiomyopathy is more common in those aged >50 yr.

RISK FACTORS:

- Consumption of more than 80 to 100 g/day of alcohol for more than 10 yr significantly increases the risk of ACM.
- The occurrence of chronic anthracycline-induced CM is correlated to cumulative dose, age, preexisting heart disease, concomitant chemotherapy, and history of mediastinal radiation therapy. Children are more susceptible to anthracycline-induced CM.
- Additional risk factors for anthracycline-induced CM include radiation therapy involving the cardiac silhouette as well as use of trastuzumab.
- Infusional dosing may reduce the risk for cardiotoxicity compared to bolus regimens.

GENETICS:

- In patients with ACM, the deletion (DD) genotype of angiotensin-converting-enzyme (ACE) is more common than insertion (II) and deletion, insertion (DI) genotypes. The underlying mechanism involves direct toxicity of ethanol to the myocardium through uncoupling of adenosine triphosphate.
- Anthracycline-induced CM is linked to an increase in cardiac oxidative stress via the pathways of mitochondrial nitric oxide synthesis, and nicotinamide adenine dinucleotide phosphate reduction.
- One study suggests that polymorphisms in the carbonyl reductase genes could be related to anthracycline-induced CM.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The majority of clinical characteristics of CMc are similar to dilated cardiomyopathy of other etiologies. Symptoms may be insidious or acute in onset.

- Acute anthracycline-induced CM can start at any time after the first dose and may present with arrhythmias (most commonly supraventricular tachycardia), left ventricular (LV) dysfunction, or pericardial disease. Typically the first manifestation of anthracycline-induced cardiotoxicity is subtle diastolic dysfunction noted on tissue Doppler. The subacute and chronic symptoms may occur 3 mo to 10 yr after the last dose. Patients usually present with heart failure. More recently, mortality has improved as a result of medical therapy with ACE inhibitors and beta-blockers. In fact, recent trials, including the OVERCOME trial, have demonstrated a benefit in preemptively treating low-cardiac-risk patients undergoing anthracycline therapy with beta-blockers and ACE-inhibitors to prevent the development of CM.
- Cardiac symptoms after 5-FU treatment include angina (most common), myocardial infarction, arrhythmia, acute pulmonary edema, cardiac arrest, and pericarditis. The mechanism of angina and myocardial infarction is coronary vasospasm and endothelial injury. The overall incidence of angina is approximately 10%.
- ACM typically occurs after yr of heavy drinking. Concurrent cirrhosis may be present. The presentation is typically heart failure with or without arrhythmia. Atrial fibrillation is the most common arrhythmia associated with chronic alcohol abuse and can also be seen with acute intoxication (holiday heart syndrome).
- Patients with cocaine-induced CM may present with adrenergic symptoms (palpitations, pallor, diaphoresis, and anxiety), hypertension, angina, atrial and ventricular arrhythmias, and heart failure.
- Anabolic steroids can cause LV hypertrophy and dilation, and lead to heart failure, arrhythmia, myocardial infarction, hypertension, and sudden death.

ETIOLOGY

- The underlying mechanism of chemotherapy-induced cardiotoxicity is not well established. Several pathways have been proposed (Fig. 1), including an increase in oxidative stress, free radical production, apoptosis, disturbance of DNA, RNA and protein synthesis, and vasospasm.
- Nutritional deficiencies, such as thiamine deficiency, also play a role in ACM.
- Table 2 describes mechanisms of ethanol-induced myocardial injury. Table 3 summarizes the effects of light-to-moderate and heavier alcohol intake on cardiovascular risk factors and outcomes.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious cardiomyopathy: Viral, HIV related, Lyme disease, Chagas disease
- Ischemic cardiomyopathy
- Dilated cardiomyopathy, related to valvular disease or hypertension
- Cirrhotic cardiomyopathy
- Tachycardia-induced cardiomyopathy
- Stress-related (takotsubo) cardiomyopathy
- Peripartum cardiomyopathy
- Genetic causes of dilated cardiomyopathy

WORKUP

- Chemical exposure history
- Electrocardiogram, serum electrolytes, renal function, and hepatic function
- Serum troponin and brain natriuretic peptide (BNP) levels
- Transthoracic echocardiogram for the evaluation of heart structure and function
- Rule out the diagnosis of coronary artery disease by coronary angiography
- Cardiac magnetic resonance (CMR) imaging can be used to evaluate for myocardial scar and fibrosis

LABORATORY TESTS

- There are no specific diagnostic tests to help differentiate CMc from other forms of

TABLE 1 Chemotherapeutic Agents Implicated in Clinical Syndromes of Cardiotoxicity

Agent	Frequency of Cardiotoxicity*	Comments
Left Ventricular Dysfunction–Heart Failure		
Chemotherapeutics		
Anthracyclines		
Doxorubicin	+++	Highly dose-dependent
Epirubicin	+	Risk factors include age (old and young), prior mediastinal radiation, history of heart disease, decreased ejection fraction; drop in ejection fraction on drug therapy, female sex (for children), and other agents (especially trastuzumab)
Idarubicin	++	Risk decreased by liposomal encapsulation or dexrazoxane
Alkylating agents		
Cyclophosphamide	+++	Primarily seen with high-dose "conditioning" regimens
Ifosfamide	+++	Risk factors are previous mediastinal irradiation and anthracycline drug therapy Also can have myocarditis, pericarditis, myocardial necrosis
Taxanes		
Paclitaxel	+/++	Also employed in paclitaxel-eluting stent
Docetaxel	+	
Proteasome inhibitor		
Bortezomib	+/++	Moderately high rates of HF seen in trials (5%), but rates only minimally higher than in patients receiving dexamethasone
Targeted Therapeutics		
Monoclonal antibodies		
Trastuzumab	++	Not common as single agent Increased risk with anthracyclines, paclitaxel, cyclophosphamide
Pertuzumab	+/++	Targets HER2 Rates of LV dysfunction as high as ~25% in one series
Bevacizumab	+/++	Targets VEGF-A (ligand for VEGFRs) and serves as a trap, preventing interaction with its receptor HF can be seen in setting of severe hypertension, which occurs in 10%-25% of patients, depending on dose; anthracyclines may increase HF risk
Tyrosine kinase inhibitors		
Imatinib, nilotinib	+	Can cause severe fluid retention with peripheral edema, pleural and pericardial effusion not secondary to LV dysfunction
Dasatinib	++	Same as above regarding fluid retention Can cause severe pulmonary hypertension; mechanism unclear
Sunitinib	+++	LV dysfunction common; hypertension likely plays role
Sorafenib	++	Rate of cardiotoxicity not clear as of yet
Ischemic Syndromes		
Fluorouracil, capecitabine	++	ACS; patients with CAD at increased risk Recurs with rechallenge; multiple mechanisms proposed; etiology remains unknown
Cisplatin, carboplatin	+	ACS caused by vasospasm or vascular injury Hypertension common; thromboembolism more common (see below)
Interferon-α	+	Risk of ischemia increased in patients with CAD; hypertension common
Paclitaxel	+	Myocardial ischemia in 1%-5%; serious ischemic cardiac events not common
Docetaxel	+	Limited data, but rate probably ~1%
Bevacizumab	++	Arterial thrombotic events including MI and stroke
Vinca alkaloids	+	~1% risk of cardiac events; ischemia possibly caused by coronary spasm
Sorafenib	+/++	~2.5% risk of ACS
Erlotinib, nilotinib	+/++	Limited data, but rate ~2%; concern over possible increase in peripheral vascular events
Hypertension		
Cisplatin	++++	
Bevacizumab	++++	Extremely common with all anti-VEGF therapeutics to date
Sunitinib	++++	Intrinsic in mechanism of action of these agents
Sorafenib	+++	
Venous Thrombosis		
Cisplatin	+++	Deep vein thrombosis or pulmonary embolism in 8.5%; most occur early in treatment Additional risk factors for deep vein thrombosis often present
Thalidomide	++++	Uncommon with monotherapy, but risk rises with concurrent chemotherapy
Lenalidomide	+++	See comments for thalidomide
Erlotinib	++	Rate with erlotinib plus gemcitabine ~2% over that with gemcitabine alone

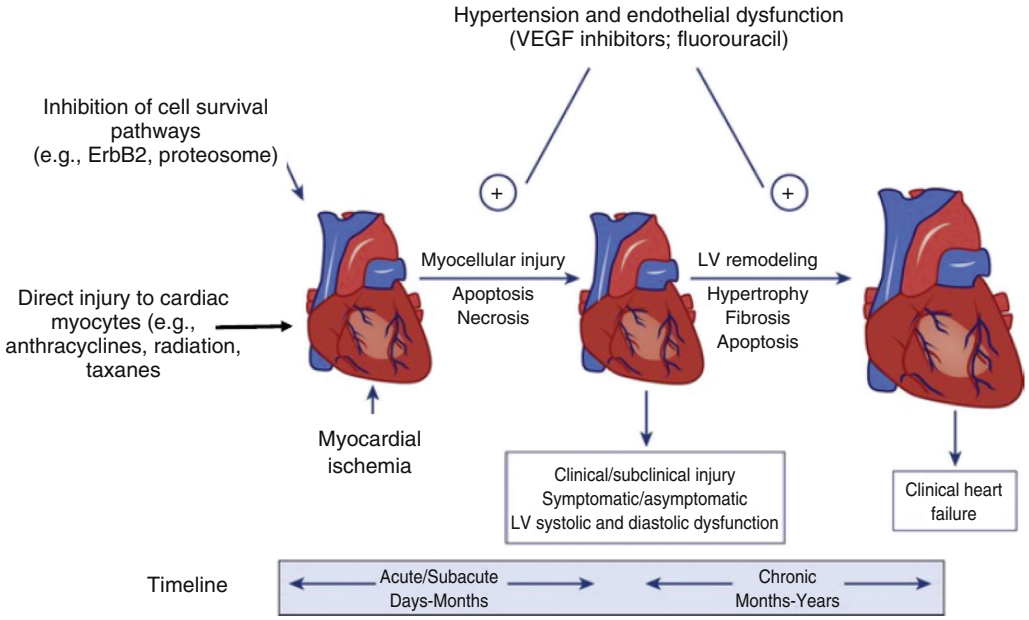

FIG. 1 Pathophysiology of chemotherapy-induced cardiotoxicity. The specific mechanisms and clinical manifestations of cardiac injury may vary according to each chemotherapy class, but the final common pathway linking the initial injury to acute, subacute, and chronic manifestations are often overlapping. Acute and subacute injury are often asymptomatic and may or may not be associated with a measurable change in ejection fraction. Chronic cardiac injury usually is associated with left ventricular *(LV)* remodeling characterized by LV enlargement, reduced ejection fraction, and eventually symptomatic heart failure. Hypertension associated with inhibitors of the vascular endothelial growth factor *(VEGF)* signaling pathway can exacerbate myocardial injury and cardiac disease progression in the acute, subacute, and chronic settings. (From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.)

TABLE 2 Mechanisms of Ethanol-Induced Myocardial Injury

Direct Toxic Effects
Uncoupling of the excitation/contraction system
Reduced calcium sequestration in the sarcoplasmic reticulum
Inhibition of the sarcolemmal adenosine triphosphate–dependent Na^+/K^+ pump
Reduction in the mitochondrial respiratory ratio
Altered substrate uptake
Increased interstitial/extracellular protein synthesis
Toxic Effect of Metabolites

CM, but the following laboratory tests are generally helpful; serum electrolytes, renal function, hepatic function, thyroid-stimulating hormone, iron profile, and inflammatory markers.

- Recent studies have suggested that early elevation of troponin levels, BNP, and myeloperoxidase following chemotherapy may be a predictor of future development of cardiomyopathy.

IMAGING STUDIES

- ECG
- Nonspecific findings of a cardiomyopathy may be present, including sinus tachycardia, nonspecific ST-T wave changes, decreased QRS voltage, interventricular conduction delay or bundle branch block, and QT interval abnormalities. In 5-FU toxicity, significant ST segment deviations may present.
- Echocardiogram
  1. Asymptomatic alcoholics may present with mild LV hypertrophy, diastolic dysfunction, LV dilation, and decrease in left ventricular ejection fraction (LVEF).
  2. Baseline LVEF should be performed before initiation of anthracycline-based chemotherapy, preferably with an echocardiogram or multigated acquisition (MUGA) scan.
     a. Anthracycline-based chemotherapy should generally be avoided for patients with an LVEF ≤40, or LVEF >40 but <50 with prior heart failure.
     b. Total doxorubicin dose should be limited to 450 mg/m^2.
     c. If baseline LVEF is ≥55%, then subsequent evaluation should be at the end of treatment if the doxorubicin dose is <200 mg/m^2 or serially at 200, 300, 350, and 400 mg/m^2 for higher doses. Doxorubicin therapy should be discontinued if there is a >15% absolute drop in LVEF, decease

TABLE 3 Qualitative Effects of Light-to-Moderate and Heavier Alcohol Intake on Cardiovascular Risk Factors and Outcomes

Cardiovascular Risk Factors and Outcomes	Light-to-Moderate Alcohol Intake (<2 Drinks per Day)	Heavier Alcohol Intake (>2 Drinks per Day)

in LVEF to ≤40%, or symptomatic congestive heart failure with an LVEF <50. There has been no direct causal link between anthracyclines and the development of heart failure with a preserved ejection fraction.

d. Peak systolic global longitudinal strain imaging (GLS) is an emerging echocardiographic measurement. A 10% to 15% early decrease in GLS by speckle tracking echocardiography during treatment seems to be the most useful parameter for the early detection of cardiotoxicity. Echocardiographic strain and strain rate imaging are sensitive, noninvasive methods for assessment of myocardial function.

- Radionuclide imaging (Fig. E2).
  1. If baseline LVEF is <50% with no prior history of heart failure, the cardiac risks vs. oncological benefits should be discussed with the patient, cardiologist, and oncologist before initiating therapy. Optimization of cardiovascular status, including hypertension control, is recommended. Cardio-protective agents such as ACE inhibitors and beta-blockers should be initiated and serial LVEF measurements done after each dose.
  2. Even after chemotherapy, periodic screening with echocardiography and/or biomarkers should be considered for up to 10 yr for those with high cumulative anthracycline doses or a history of reversible LV dysfunction during treatment.

Rx TREATMENT

ACUTE GENERAL Rx

- Treat decompensated heart failure with diuresis and inotropes if there is a low cardiac output state.
- For angina in acute cocaine intoxication or induced by 5-FU, benzodiazepines, nitrites, and calcium channel blockers are first-line therapy. If ECG provides evidence of acute myocardial infarction, patients should proceed to emergent cardiac catheterization and coronary angiography.

CHRONIC Rx

- Dexrazoxane is an ethylenediaminetetraacetic acid-like chelator that acts by binding to iron, which prevents anthracycline cardiotoxicity. Cardiooncology experts suggest a 10:1 ratio of dexrazoxane to anthracycline, given 15 to 30 min before doxorubicin administration. However, its routine use is not currently recommended in adults except in cases of a cumulative doxorubicin dose of 300 mg/m^2 or greater with an ongoing indication to receive doxorubicin-based chemotherapy.
- Those developing anthracycline-induced CM generally should not be rechallenged with the drug, as the cardiac damage is usually irreversible due to cell death.
- Beta-blocker: Carvedilol and nebivolol have been shown to have protective effects on LV systolic function during anthracycline therapy. Larger trials with metoprolol have shown no benefit.
- The following ACE inhibitors and angiotensin receptor blocker (ARB) have been shown to protect against anthracycline cardiotoxicity: Enalapril, ramipril, and telmisartan. Results from the PRADA trial suggest that use of the ARB candesartan mitigates anthracycline-induced decline in LVEF.
- There is growing interest in the use of statins for primary prevention of anthracycline-mediated cardiotoxicity based on their antioxidant and anti-inflammatory properties, although a cardioprotective effect has not been established.
- Thiamine, folic acid, and multivitamins are adjunctive treatments for ACM. Abstinence can usually reverse the cardiomyopathy.

DISPOSITION

Prognosis depends on the dosage of chemicals and the severity of LV dysfunction.

REFERRAL

Close follow-up with a cardiooncologist.

PEARLS & CONSIDERATIONS

The presentation of chemotherapy-induced cardiac toxicity ranges from an asymptomatic decline in LVEF to overt heart failure. The incidence is dose-dependent in the case of anthracyclines and may manifest up to 10 yr after the initial exposure. Therefore, regular clinical follow-up with echocardiographic surveillance is advised.

PREVENTION

- Noninvasive assessment of LV function before, during, and after anthracycline-containing chemotherapy with echocardiography or MUGA scan.
- To reduce the risk of doxorubicin cardiotoxicity, the lifetime cumulative dosage should be limited to <450 mg/m^2 in adults.
- Other approaches include the use of infusion rather than bolus dosing, liposomal encapsulated doxorubicin, less cardiotoxic analogs of doxorubicin such as epirubicin, and co-administration of protective agents such as dexrazoxane.
- 5-FU treatment should be terminated if cardiac symptoms develop. Readministration is not recommended.

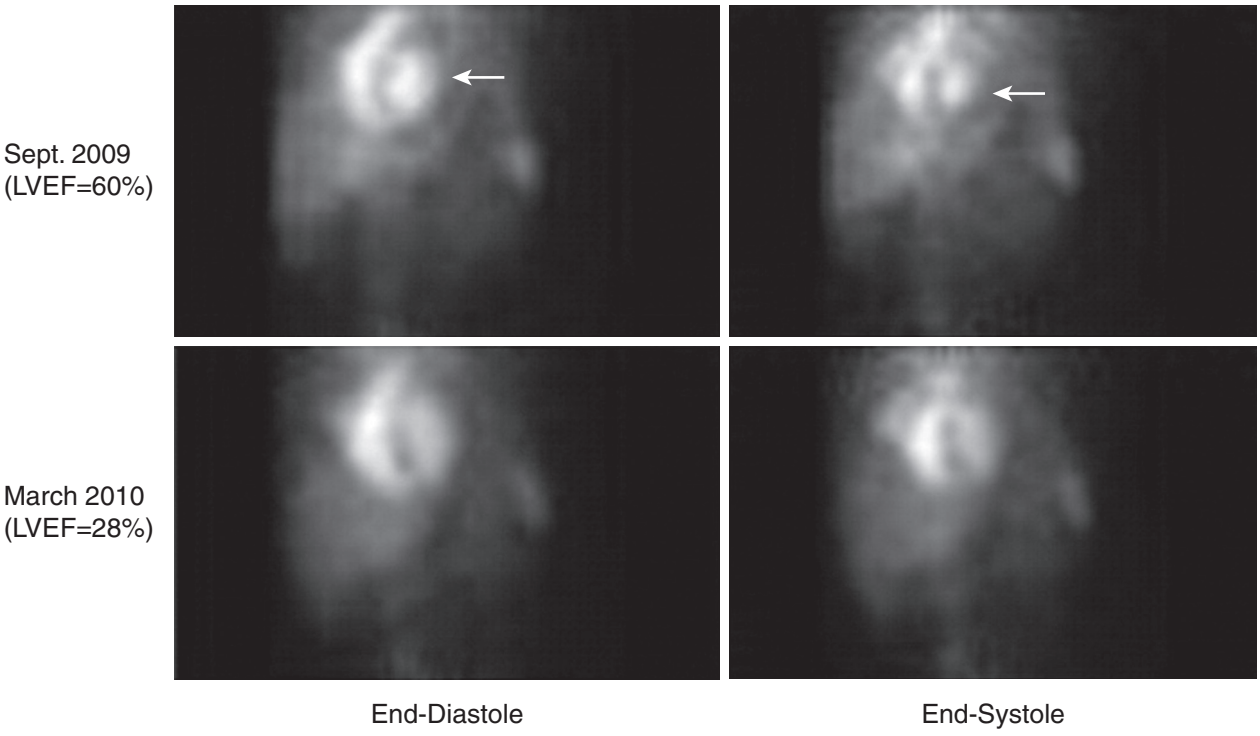

FIG. E2 Technetium-99m-pertechnetate multigated acquisition scans in a 47-year-old woman with breast cancer treated with doxorubicin. The top scan was taken before initiation of doxorubicin and cyclophosphamide therapy in September 2009. The left ventricular ejection fraction *(LVEF)* (left ventricular end-diastolic counts minus left ventricular end-systolic counts/left ventricular end-diastolic counts 100) was calculated at 60%. The bottom scan was taken in March 2010 after treatment with a total doxorubicin dose of 451 mg/m^2. Left ventricular ejection fraction was calculated at 28%. Left ventricle (*white arrows*) during end-diastole and end-systole. Cardiomyopathy, Dilated PTG

BASIC INFORMATION

DEFINITION

Dilated cardiomyopathy (DCM) describes a group of diseases involving the myocardium and characterized by dilation and impaired contraction of one or both ventricles that is not wholly the result of hypertension, coronary atherosclerosis, valvular dysfunction, congenital, or other structural heart disease. As a result, the systolic function of the heart is impaired, and the patient may develop overt heart failure, atrial and/or ventricular arrhythmias, and sudden death. The disease is considered idiopathic if primary and secondary causes of heart disease are excluded.

SYNONYMS

Congestive cardiomyopathy
Idiopathic cardiomyopathy

ICD-10CM CODES

B33.24	Viral cardiomyopathy
I11.0	Hypertensive heart disease with heart failure
I42.0	Dilated cardiomyopathy (includes congestive cardiomyopathy)
I42.9	Cardiomyopathy, unspecified (includes cardiomyopathy [primary] [secondary] NOS)
I43	Cardiomyopathy in diseases classified elsewhere
I50.20 to I50.9	(Unspecified, acute, chronic, or acute on chronic) + (systolic, diastolic, or combined) (congestive) heart failure
O90.3	Peripartum cardiomyopathy

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: DCM is the most common form of cardiomyopathy, comprising approximately 60% of all cases.

PREVALENCE: The estimated age-adjusted prevalence of DCM in the U.S. in general is approximately 36 per 100,000 or 1:2500. The incidence is approximately 5 to 8 per 100,000 persons per yr.

PREDOMINANT AGE: Although DCM can occur at any age, the incidence is greatest in the third and fourth decades of life in men.

GENETICS: African Americans have a three-fold increased risk for developing DCM, irrespective of comorbidities or socioeconomic factors, compared with whites.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Affected patients may present in a number of ways and the etiology most often is elucidated by obtaining a focused history. The patient may display common symptoms of congestive heart failure, which may be of insidious or sudden onset. The patient may also be asymptomatic and the diagnosis made by the incidental finding of cardiomegaly on a chest x-ray. Classical signs of heart failure may be absent. When present, findings are indistinguishable from other heart failure syndromes, including:

- Increased jugular venous pressure
- Narrow pulse pressure
- Pulmonary rales, hepatomegaly, peripheral edema
- S3, S4
- Mitral regurgitation, tricuspid regurgitation (less common)

ETIOLOGY

DCM can be attributed to genetic and nongenetic causes, including hypertension, valve disease, inflammatory/infectious processes, and toxins.

- Idiopathic (often a viral infection that cannot be confirmed)
- Infections (viral [human herpesvirus 6, influenza, echovirus, cytomegalovirus, Coxsackie B, adenovirus, parvovirus, HIV], rickettsial, mycobacterial, toxoplasmosis, trichinosis, Chagas disease)
- Ischemic heart disease
- Alcoholism (15% to 40% of all cases in Western countries)
- Uncontrolled tachyarrhythmia ("tachycardia-mediated")
- Sleep apnea–obstructive or nonobstructive
- Cirrhotic (not necessarily alcohol-induced)
- End-stage renal disease–related
- Nutritional deficiencies (selenium, L-carnitine, thiamine)
- Peripartum (greatest risk from last trimester of pregnancy to 6 mo postpartum)
- Chemotherapeutic (anthracycline, doxorubicin, daunorubicin) or pharmacologic agents (antiretrovirals, phenothiazines) (see "Cardiomyopathy, Chemical-Induced")
- Substance abuse (cocaine, heroin, organic solvents, "glue-sniffer's heart")
- Postmyocarditis
- Toxins (cobalt, lead, phosphorus, carbon monoxide, mercury) Collagen-vascular disease (systemic lupus, rheumatoid arthritis, polyarteritis, dermatomyositis, sarcoidosis)
- Hereditary familial neuromuscular disorders (e.g., muscular dystrophy, myotonic dystrophy)
- Endocrine dysfunction (acromegaly, osteogenesis imperfecta, myxedema, thyrotoxicosis, diabetes)
- Hematologic (e.g., sickle cell anemia, hereditary sideroblastic anemias and thalassemias, hypereosinophilia, hereditary hemochromatosis)
- Stress-induced (i.e., takotsubo or broken heart syndrome)
- Left ventricular (LV) noncompaction
- Autoimmunity ("anti-heart antibodies" [AHAs; beta-1 adrenoceptor, alpha-myosin heavy chain, beta-myosin heavy chain, myosin light chain] are hypothesized to cause DCM based on animal studies) appears to be applicable to humans, as AHAs can be detected in 38% of patients with an idiopathic DCM
- *TTN* truncating mutations (mutations in *TTN*, the gene encoding the sarcomere protein titin) are a common cause of DCM, occurring in approximately 25% of familial cases of idiopathic DCM and in 18% of sporadic cases

DIAGNOSIS

DCM is a diagnosis of exclusion, made after ruling out other potential causes of myocardial dysfunction.

DIFFERENTIAL DIAGNOSIS

- Coronary atherosclerosis, that is, left ventricular dysfunction secondary to ischemia and/or myocardial infarction
- Valvular dysfunction (especially aortic and mitral regurgitation)
- Other cardiomyopathies (restrictive, hypertrophic)
- Pulmonary disease (embolism, obstructive, restrictive)
- Pericardial abnormalities (constrictive pericarditis, tamponade)
- Hypothyroidism/myxedema
- Athlete heart

WORKUP

- Medical history: Emphasis on symptoms of dyspnea, orthopnea, paroxysmal nocturnal dyspnea, weight gain, palpitations, fatigue, or signs of systemic and pulmonary embolism, substance abuse history, possible toxin exposures (especially occupational)
- Physical exam (see "Physical Findings & Clinical Presentation")
- Testing (see "Laboratory Tests" and "Imaging Studies" for more detail): Laboratory, chest x-ray, ECG, echocardiogram, cardiac catheterization; myocardial biopsy is not routinely recommended, unless acute myocarditis requiring immunosuppressive therapy is considered (e.g., giant cell myocarditis)

LABORATORY TESTS

- Chemistries/metabolites (deficiencies), renal function tests (renal dysfunction)
- Cardiac biomarkers (elevation of cardiac troponin or brain natriuretic peptide)
  1. Persistently increased cardiac troponin T levels are a marker of poor outcome in cardiomyopathy patients
- Endocrine (particularly thyroid)
- Iron studies (hemochromatosis, deficiency)
- Rheumatologic and inflammatory (antinuclear antibody, erythrocyte sedimentation rate, and C-reactive protein tests)
- Others as indicated (HIV, Lyme, neurohormonal)

IMAGING STUDIES

Chest x-ray:

- Cardiac silhouette enlargement (particularly left ventricle)
- Pulmonary vascular redistribution and congestion (Kerley B lines, cephalization of vasculature), pleural effusion (may appear as unilateral, most often on the right side)

ECG:

- ECG findings are typically nonspecific, and sinus tachycardia is usually a reflection of underlying heart failure. Large voltage in precordial leads and low voltage in limb leads may be seen in advanced disease
- Intraventricular conduction defects and left bundle branch block

- Arrhythmias (atrial fibrillation, premature ventricular or atrial contractions, ventricular tachycardia)

Echocardiogram (Fig. 1):

- Low ejection fraction with global hypokinesis
- Four-chamber enlargement (LV enlargement usually predominates)
- Mitral or tricuspid regurgitation ("secondary" regurgitation from tethering due to incomplete leaflet closure caused by ventricular dilation)

Cardiac catheterization:

- On initial presentation to exclude obstructive epicardial coronary artery disease

Cardiac magnetic resonance imaging (CMRI):

- Particularly if infiltrative or inflammatory etiology suspected

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Treatment of underlying disease (systemic lupus, alcoholism)
- Dietary sodium restriction (<2 g/day)
- Exercise training has been shown to be associated with reduced risk for hospitalization and death in patients with history of heart failure in limited trials; enrollment in a formal cardiac rehabilitation program may be beneficial in improving patient's functional status

ACUTE GENERAL Rx

- Identify and treat the etiology of the acute exacerbation, when able. A helpful mnemonic is FAILURE: **F**ailure to take medications, **a**nemia/**a**rrhythmia, **i**schemia/**i**nfection/**i**nfarction, **l**ifestyle (dietary indiscretion), **u**pregulation of cardiac output (hyperthyroidism or pregnancy), **r**enal failure, **e**mbolus (pulmonary).
- Diuretics are indicated for all patients with current symptoms or history of heart failure and reduced left ventricular ejection fraction (LVEF) with evidence of volume overload (see "Physical Findings & Clinical Presentation") to improve symptoms. It is important to note that diuretics have not been shown to improve mortality rates.
- Patients with associated coronary atherosclerosis (angina, ECG changes, reversible defects on myocardial perfusion imaging) may benefit from percutaneous or surgical revascularization.

CHRONIC Rx

- Diuretics as noted in "Acute General Rx."
- ACE inhibitors (and angiotensin receptor blockers) have been shown to have favorable effects on ventricular remodeling in patients with cardiomyopathy and a demonstrable mortality benefit in these patients. They also reduce afterload and improve cardiac output. Recommended in all patients with reduced LV systolic function (ejection fraction [EF] ≤40%), regardless of symptoms unless specific contraindications exist.
- Beta-blockers work by inhibiting the adverse effects of the sympathetic nervous system in patients with ventricular systolic dysfunction (EF ≤40%). *Only* carvedilol, long-acting metoprolol succinate, and bisoprolol have shown a mortality benefit in patients with LV systolic dysfunction. Unless specifically contraindicated, they should be started after the acute exacerbation has resolved and titrated to the maximum tolerated dose.
- Aldosterone antagonists (spironolactone and eplerenone) have shown mortality benefit along with a decreased rate of hospitalization for heart failure in patients with symptomatic heart failure and reduced LV systolic function (EF ≤35%). They should be used following label guidelines and with close monitoring of renal function and potassium.
- Hydralazine/nitrates improve both morbidity and mortality, and should be considered in the following populations: African Americans with persistent New York Heart Association (NYHA) class III or IV heart failure with an EF <40%, on optimal medical therapy (beta-blocker and angiotensin-converting enzyme [ACE] or angiotensin II receptor blockers [ARB]); and those unable to take ACE inhibitors or ARBs due to intolerance, hypotension, or renal insufficiency.

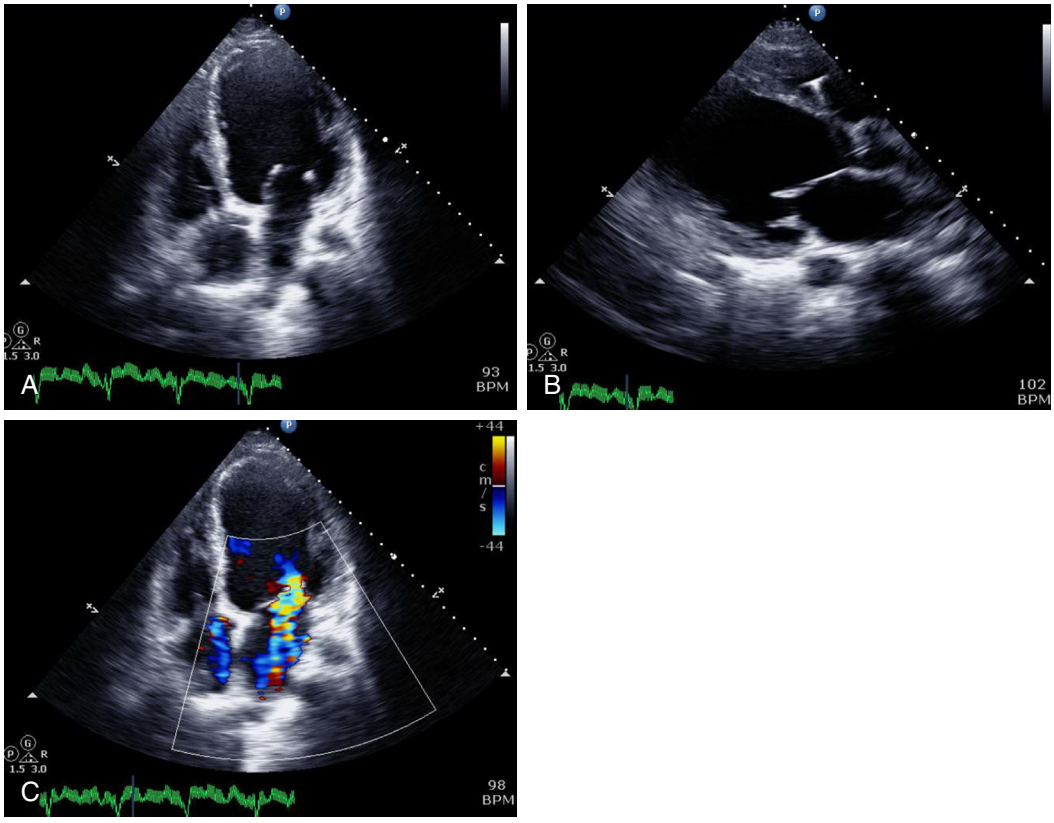

FIG. 1 2-Dimensional echocardiogram in a 37-year-old male with non-ischemic dilated cardiomyopathy showing a dilated, thinned left ventricle (LV). **A,** Apical four chamber. **B,** Parasternal long axis of the left ventricle. **C,** Mitral regurgitation ("secondary" regurgitation due to incomplete coaptation of the mitral valve leaflets). (Courtesy of J. Bell, MD.)

TABLE 1 Factors Associated with an Adverse Outcome in Dilated Cardiomyopathy

Clinical	Noninvasive	Invasive
NYHA Class III/IV	Low LV ejection fraction	High LV filling pressures
Increasing age	Marked LV dilation	
Low exercise peak oxygen consumption	Low LV mass	
Marked intraventricular conduction delay	≥Moderate mitral regurgitation	
Complex ventricular arrhythmias	Abnormal diastolic function	
Abnormal signal-averaged ECG	Abnormal contractile reserve	
Evidence of excessive sympathetic stimulation	Right ventricular dilation or dysfunction	
Protodiastolic gallop (S_3)		
Elevated serum BNP		
Elevated uric acid		
Decreased serum sodium		

BNP, Brain natriuretic peptide; *ECG,* electrocardiogram; *LV,* left ventricular; *NYHA,* New York Heart Association.
From Hare JM: The dilated, restrictive, and infiltrative cardiomyopathies. In Bonow RO et al (eds): *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 9, St Louis, 2011, Saunders.

- Digoxin is used for its positive inotropic effects in heart failure due to systolic dysfunction. It has no mortality benefit but has been shown to improve quality of life in appropriately selected patients.
- Angiotensin receptor-neprilysin inhibitor (ARNI), sacubitril-valsartan, approved in the U.S in 2015, was developed to block harmful effects of renin-angiotensin-aldosterone system (RAAS) activation while raising levels of endogenous vasoactive peptides degraded by neprilysin, such as natriuretic peptides, bradykinin, and adrenomedullin. Used in place of an ACE inhibitor or angiotensin receptor blocker and on top of optimal medical therapy in patients with class II-IV heart failure and an EF of 40% or less was found to significantly reduce multiple heart failure end points, including death, hospitalizations, and cardiovascular death in comparison to enalapril.
- Ivabradine was FDA approved in 2015 for patients with stable, symptomatic chronic heart failure with left ventricular ejection fraction ≤35% who are in sinus rhythm with resting heart rates ≥70 beats/min and either of the following: (1) Are on maximally tolerated doses of beta-blockers or (2) have a contraindication to beta-blocker use. It acts by blocking the hyperpolarization-activated cyclic nucleotide-gated (HCN) channel responsible for the cardiac pacemaker I_f current, which regulates heart rate.

DISPOSITION

- Annual mortality rate is 20% in patients with moderate heart failure, and it exceeds 50% in patients with severe heart failure. Once symptomatic, hospitalizations are frequent and readmission rates are high (>50% at 3 mo). A multispecialty treatment approach (e.g., primary care, cardiology, nutrition, cardiac rehabilitation) is recommended.
- Factors associated with an adverse outcome in DCM are described in Table 1.

REFERRAL

- Implantation of a cardiac defibrillator for primary prevention of sudden cardiac death can be considered for patients with LVEF ≤35% and on optimal medical therapy regardless of symptom status.
- Patients with LVEF <35%, left bundle branch block on ECG (QRS ≥0.13 sec), and persistent heart failure symptoms may benefit from cardiac resynchronization therapy via a biventricular pacemaker.
- Consider heart transplantation for relatively young patients (there is no precise age threshold) free of other significant comorbid conditions who are unresponsive to medical therapy. DCM is the reason for 45% of all heart transplantations in the U.S.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients should be encouraged to restrict or eliminate alcohol and reduce sodium intake (<2 g daily).
- Patients may benefit from daily weight checks as a means of early detection of volume overload and decompensated heart failure.
- Vulnerability to cardiomyopathy among chronic alcohol abusers is partially genetic and related to the presence of the ACE DD genotype.
- Idiopathic DCM is often familial, and apparently healthy relatives may have latent, early, or undiagnosed disease. Echocardiographic evaluation of family members is recommended.
- Incorporation of sequencing approaches that detect *TTN* truncations into genetic testing for DCM may substantially increase test sensitivity and allow earlier diagnosis of DCM.

BASIC INFORMATION

DEFINITION

Hypertrophic cardiomyopathy (HCM) is most commonly an autosomal dominant myocardial disorder characterized by disorganized myocyte architecture and marked thickening (hypertrophy) of the left ventricular wall (≥15 mm), without dilation, *not explained by another cardiac or systemic disorder*. The interventricular septum is the most common site of enlargement, though hypertrophy may involve other focal regions or may be concentric. HCM may result in hemodynamically significant obstruction within the left ventricular outflow tract (LVOT) and/or impairment of the diastolic function of the left ventricle. However, about one third of patients have no obstruction at rest or with provocation.

SYNONYMS

HCM
Hypertrophic cardiomyopathy
Idiopathic hypertrophic subaortic stenosis (IHSS)
Hypertrophic obstructive cardiomyopathy (HOCM)
Hypertrophic nonobstructive cardiomyopathy
Asymmetric septal hypertrophy (ASH)
Familial hypertrophic cardiomyopathy

ICD-10CM CODES

I42.1	Obstructive hypertrophic cardiomyopathy (includes hypertrophic subaortic stenosis)
I42.2	Other hypertrophic cardiomyopathy (includes nonobstructive hypertrophic cardiomyopathy)
I42.8	Other cardiomyopathies
I42.9	Cardiomyopathy, unspecified (includes cardiomyopathy [primary] [secondary] not otherwise specified)

EPIDEMIOLOGY & DEMOGRAPHICS

- Prevalence in the general population in the U.S., China, and Japan is estimated to be between 1/500 to 1/200 (the most common genetically transmitted cardiovascular disease).
- HCM is the most common cause of sudden cardiac death in young athletes (more commonly among blacks).
- There is equal prevalence in men and women (probably underdiagnosed in women).
- It occurs across ethnicities, perhaps underdiagnosed among blacks.
- Mortality rate is approximately 1%/yr, as high as to 2%/yr in children.
- The most common form of the disease is familial (60% to 70% of cases), and it follows an autosomal dominant inheritance pattern with variable expression.
- Spontaneous mutations can also occur, accounting for approximately 20% of cases. It is otherwise indistinguishable from the familial form.
- A variant form seen in the elderly (5% to 10% of cases) has a better prognosis, and it is not typically associated with sudden cardiac death.
- The familial form is usually diagnosed in young patients. It is most often caused by a mutation in one of the contractile protein genes of the cardiac sarcomere. See "Etiology" for more details.
- Nonsarcomeric genetic mutations that cause storage disease (e.g., Fabry disease) have a very similar clinical presentation.
- Apical HCM is a variant more common among Asians: As many as 41% of Chinese HCM and 15% of Japanese HCM patients. Clinically there is no LVOT obstruction.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients may have subtle symptoms of progressive congestive heart failure (CHF). At the time of diagnosis, most patients are asymptomatic, referred and diagnosed based on family history. HCM may be suspected on the basis of abnormalities found on physical examination. Classic findings include:

- Harsh, systolic, crescendo–decrescendo murmur at the left sternal border or apex. The murmur increases with maneuvers that decrease venous return or LV size (Valsalva, standing), and decreases with those that increase venous return or afterload (squatting, hand grip, post-Valsalva release).
- Paradoxical splitting of S2 (if left ventricular obstruction is present).
- S4 may be present.
- Double or triple LV apical impulse ("triple ripple": Atrial contraction, early rapid ejection, and late slow ejection).
- Pulsus bisferiens (double pulsation on palpation of the carotid pulse).

Increased obstruction can occur with:

- Drugs: Digitalis, β-adrenergic stimulators (isoproterenol, dopamine, epinephrine), nitroglycerin, vasodilators, diuretics, alcohol, inhalation of amyl nitrate
- Hypovolemia
- Tachycardia
- Valsalva maneuver
- Standing position

Decreased obstruction is seen with:

- Drugs: β-adrenergic blockers, calcium channel blockers, disopyramide, α-adrenergic stimulators
- Volume expansion
- Bradycardia
- Hand-grip exercise
- Squatting position
- Release phase of the Valsalva maneuver

Clinical manifestations are as follows:

- Syncope or presyncope (usually seen with exercise)
- Angina
- Palpitations
- Sudden cardiac death
- Heart failure (typically with advanced stages): Dyspnea on exertion, orthopnea, edema, increased jugular venous pressure, paroxysmal nocturnal dyspnea

ETIOLOGY

- Genetic: Autosomal dominant trait with variable penetrance caused by mutations in multiple genes encoding proteins of the cardiac sarcomere and calcium regulation. To date, >1400 mutations have been identified among at least 13 genes, with variable phenotypes, expressivity, and penetrance. The most vigorous evidence indicates that eight genes are known to definitively cause HCM: Beta myosin heavy chain, myosin binding protein C, troponin T, troponin I, tropomyosin alpha-1 chain, actin, regulatory light chain, and essential light chain. HCM may be caused by a single mutation in one of two alleles; however, 5% of patients have at least two mutations. Sarcomeric protein gene mutations account for up to 60% of cases of HCM.
- Metabolic: Most are autosomal recessive, but some are X-linked. Most commonly, they are due to Anderson-Fabry disease (a lysosomal storage disease). Other metabolic etiologies include the glycogen storage diseases Pompe and Danon, AMP-kinase (PRKAG2), and carnitine disorders.
- Mitochondrial: These comprise autosomal dominant, autosomal recessive, X-linked, and maternally inherited traits. Most frequently, they are due to mutations in the respiratory chain protein complexes. The age of onset and severity of involvement are variable.
- Neuromuscular: These are most commonly associated with Friedreich ataxia, but they are also associated with *FHLI*.
- Malformation syndromes: These etiologies include Noonan (formerly referred to as LEOPARD), Costello, and cardiofaciocutaneous.
- Amyloidosis: These include familial ATTR, wild-type TTR (senile), and amyloid light-chain (AL) amyloidosis.
- Drug-induced: Tacrolimus, hydroxychloroquine, and steroids.
- Sporadic occurrence.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hypertensive heart disease
- Aortic stenosis
- Subaortic stenosis
- Athlete heart
- Volume depletion

WORKUP

- Medical history: Unexplained clinical manifestations and/or family history of sudden death.
- Physical exam: See "Physical Findings & Clinical Presentation."
- Genetic counseling with or without testing.
- ECG is abnormal in 75% to 95% of patients, although there are no pathognomonic findings. Typical findings include:
  1. Left ventricular (LV) hypertrophy (abnormally tall R waves in the precordial leads) in up to 80% of patients (Fig. E2).

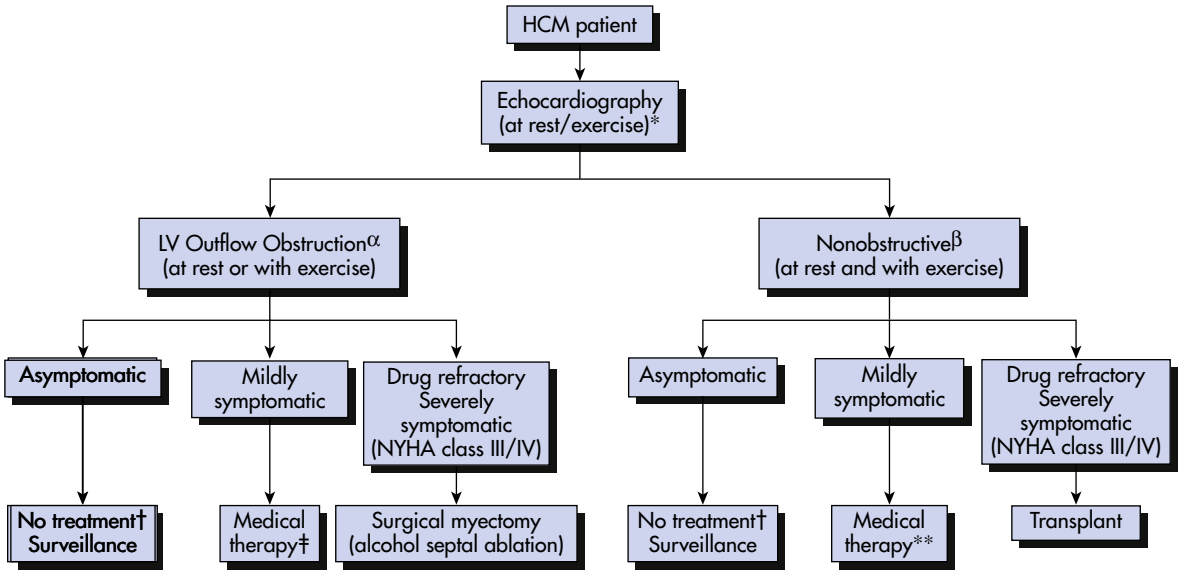

FIG. 1 Heart failure management strategies starting with echocardiography. *Patients without LV outflow tract gradient (<30 mm Hg) at rest should undergo stress (exercise) echocardiography. †No data on benefit of pharmacologic therapy, although beta-blockers often are administered prophylactically in clinical practice. **Beta-blockers, calcium channel antagonists, and possibly diuretics administered judiciously. ‡Usually, beta-blockers or calcium channel antagonists (verapamil), or disopyramide. α, generally regarded, by definition, as ≥30 mm Hg outflow gradient, but ≥50 mm Hg when septal reduction intervention is considered (i.e., septal myectomy; alcohol ablation). β, no or trivial (<30 mm Hg) outflow gradient at rest and with exercise. *HCM,* Hypertrophic cardiomyopathy; *LV,* left ventricle; *NYHA,* New York Heart Association. (From Maron BJ et al: State-of the art review: hypertrophic cardiomyopathy: present and future, with translation into contemporary cardiovascular medicine. *J Am Coll Cardiol* 2014;64:83, in Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

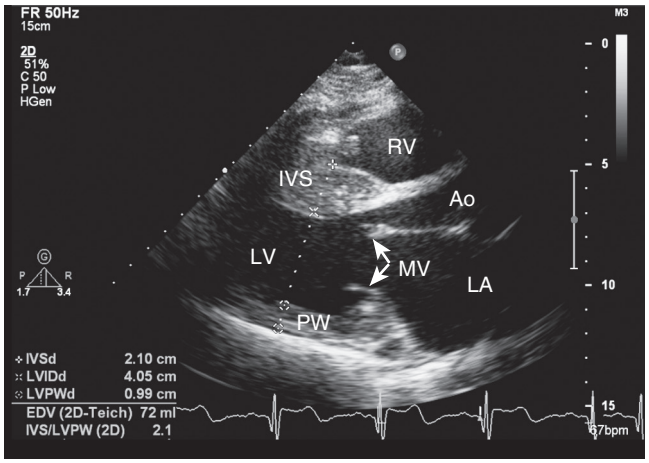

FIG. 3 Echocardiographic appearance of hypertrophic cardiomyopathy. Parasternal long-axis view from a patient with hypertrophic cardiomyopathy demonstrating asymmetrical septal hypertrophy. The interventricular septum (marked by *arrow*) measures 2.1 cm; the posterior wall measures 0.99 cm. *Ao,* Aorta; *IVS,* interventricular septum; *LA,* left atrium; *LV,* left ventricle; *MV,* mitral valve; *PW,* posterior wall; *RV,* right ventricle. (From Issa Z et al: *Clinical arrhythmology and electrophysiology,* ed 2, Philadelphia, 2012, Saunders.)

2. Abnormal Q waves in lateral and inferior leads.
3. T wave inversions (associated with the apical hypertrophy predominant variant).

- Echocardiography (Fig. 3) is usually diagnostic as the majority of patients have significant LV hypertrophy (See "Imaging Studies" for details) and should be repeated every 12 to 24 months or as clinically needed.
- 24-hour Holter monitor to screen for potentially lethal ventricular arrhythmias (principal cause of syncope or sudden death in obstructive cardiomyopathy) should be performed at the initial diagnosis and in patients that subsequently develop palpitations, lightheadedness, or syncope. The presence of these arrhythmias identifies patients who are candidates for implantable cardioverter-defibrillator (ICD) therapy.
- In the absence of significant LVOT obstruction, exercise testing is indicated at diagnosis and annually thereafter to evaluate for symptoms and response to exercise. A drop in systolic blood pressure by at least 20 mmHg or failure to augment by at least 20 mmHg with exercise are markers of poor prognosis and are indicators for referral for myotomy/myomectomy. Cardiopulmonary exercise testing can provide objective evidence for worsening diseases, but need only be performed every 2 to 3 yr.
- Biomarkers of myocardial fibrosis in HCM include brain natriuretic peptide and high-sensitivity cardiac troponin T and I. Other labs include complete blood count, basic metabolic panel, liver function test, thyroid stimulating hormone, serum protein electrophoresis, urine protein electrophoresis free light chain ratio (Kappa/Lambda).

- Screening for sarcomere protein gene mutations in family members of patients with HCM can identify a broad subgroup of patients with increased propensity toward long-term impairment of left ventricular function and adverse outcome, irrespective of the myofilament (thick, intermediate, or thin) involvement.
- In individuals with pathogenic mutations who do not express the HCM phenotype, it is recommended to perform serial electrocardiogram (ECG), transthoracic echocardiogram (TTE), and clinical assessment at periodic intervals (12 to 18 months in children and adolescents and about every 5 yr in adults), based on the patient's age and change in clinical status.
- Endomyocardial biopsy may be helpful to rule out diseases other than HCM if a diagnosis remains inconclusive after extensive testing.

IMAGING STUDIES

- Chest x-ray may be normal or show cardiomegaly.
- Two-dimensional echocardiography is used to establish the diagnosis and assess the severity of obstruction when present. LV wall thickness will usually be ≥15 mm (although some may be genetically positive but phenotype negative), and most patients (up to 95%) will have asymmetric (ratio of septum thickness to left ventricular wall thickness >1.3:1) LV wall hypertrophy. Symmetric LV hypertrophy is less common. The septum is most often affected, followed by the left ventricular midcavity and apex. In addition, 25% to 30% of patients will manifest systolic anterior motion (SAM) of the anterior leaflet of the mitral valve, causing obstruction of the LVOT and mitral regurgitation. Two-dimensional strain imaging echocardiography is useful for differentiation of HCM and cardiac amyloidosis from other causes of ventricular wall thickening. Up to 80% of HCM patients will also have diastolic dysfunction as evidenced by pulsed mitral valve inflow pattern and tissue Doppler.
- Cardiac MRI or cardiac CT may be of diagnostic value when echocardiographic studies are technically inadequate. MRI is also useful in identifying unusual segmental hypertrophy undetectable by standard echocardiography and can detect myocardial replacement fibrosis (an independent predictor of adverse cardiac outcomes and ventricular arrhythmias) using late gadolinium enhancement. cardiac magnetic resonance evaluation may be considered every 5 yr or every 2 to 3 yr in patients with progressive disease.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid volume depletion: An underfilled left ventricle causes closer approximation of the hypertrophic interventricular septum and anterior mitral valve leaflet, worsening the outflow tract obstruction and mitral regurgitation, potentially leading to dizziness, hypotension, and/or syncope.
- Exercise restriction: The risk of sudden cardiac death is increased by exercise in HCM patients and rapid heart rates may cause LV underfilling as described above; therefore, participation in competitive sports and intense physical activity should be avoided. As a part of a healthy lifestyle, low-intensity aerobic exercise is reasonable.
- Avoidance of alcohol: Alcohol use (even in small amounts) may result in increased obstruction of the left ventricular outflow tract. Other stimulants such as cocaine and other sympathomimetic recreational drugs should also be avoided.

ACUTE GENERAL Rx

- Therapy for HCM is directed at blocking the effect of catecholamines and generally avoiding vasodilator or diuretic agents that can exacerbate the dynamic left ventricular outflow tract obstruction.
- Beta-blockers' beneficial effects on symptoms (principally dyspnea and chest pain) and exercise tolerance appear to be largely a result of a decrease in the heart rate with consequent prolongation of diastole and increased passive ventricular filling. By reducing the inotropic response, beta-blockers may also reduce myocardial oxygen demand and decrease the outflow gradient during exercise, when sympathetic tone is increased. Dose titration to a resting heart rate of less than 65 bpm is recommended.
- Nondihydropyridine calcium channel blockers (e.g., verapamil [preferred], diltiazem) can also decrease left ventricular outflow obstruction through a mechanism similar to beta-blockers. However, they are mainly second-line agents used in patients who cannot tolerate beta-blockers as they also theoretically have vasodilatory properties that may worsen severe outflow tract gradients.
- Disopyramide is an antiarrhythmic that is also a negative inotrope, resulting in further decrease in outflow gradient. It is sometimes used in combination with beta-blockers.
- Prophylactic antibiotics before dental, GI, and genitourinary procedures are no longer recommended according to the American Heart Association (AHA) guidelines.
- Avoid use of digitalis, intravenous inotropes, dihydropyridine calcium channel blockers (e.g., nifedipine, amlodipine), nitrates, and vasodilators.
- Diuretics, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers should be used with caution.
- Intravenous phenylephrine (or another pure vasoconstricting agent) is recommended for the treatment of acute hypotension in patients with obstructive HCM who do not respond to fluid administration.
- ICDs are a safe and effective therapy in HCM patients prone to ventricular arrhythmias. In their practice guidelines, the major cardiology societies (AHA/ACC/HRS) give a strong recommendation (Class I) for ICD implantation in all patients with HCM who have had an episode of sustained ventricular tachycardia or fibrillation. In addition, they endorse the prophylactic placement of an ICD (Class IIa recommendation) for patients with one or more of the major risk factors for sudden cardiac death (outlined in "Disposition"). In patients with New York Heart Association (NYHA) functional class III or IV heart failure symptoms on maximal medical therapy, an ICD also may be considered when ejection fraction (EF) is less than or equal to 50%.
- Dual-chamber pacing may provide symptomatic relief of symptoms attributable to LVOT obstruction and refractory to medical therapy.
- Systolic dysfunction in patients with HCM is defined as an EF of less than or equal to 50%, at which point medical therapy should follow guidelines for heart failure with reduced EF (ACE inhibitors, angiotensin II receptor blockers, beta-blockers, etc.).
- HCM patients are at an increased risk of atrial fibrillation (AF) as well as systemic thromboembolism. AF occurs in over 20% of the HCM population. AF is an important source of symptoms, morbidity, and mortality and correlates to a worse prognosis. Anticoagulation for AF is indicated independent of CHA_2DS_2-VASc score and should aim for thromboembolic risk mitigation with a vitamin K antagonist (unless contraindicated) and symptom alleviation via rhythm (generally preferred due to poor tolerance of AF with HCM) or rate control. If a vitamin K antagonist cannot be used in a patient (due to inability to maintain a therapeutic INR, inability to adequately perform INR monitoring, or other side effects), the 2014 ESC HCM (Class Ib) and 2014 ACC/AHA/HRS AF (Class Ic) guidelines recommend the use of direct thrombin or factor Xa inhibitors, even though there is no data on their use in patients with HCM.
- Fig. 1 summarizes heart failure management strategies.

DISPOSITION

HCM is not a static disease. Some adults may experience subtle regression in wall thickness, whereas others (~5% to 10%) paradoxically evolve into an end-stage cardiomyopathy resembling dilated cardiomyopathy, characterized by cavity enlargement, left ventricular wall thinning, and systolic dysfunction. Patients with HCM are at increased risk for sudden death, especially if the onset of symptoms began during childhood. Severe left ventricular outflow obstruction at rest is also a strong, independent predictor of severe symptoms of heart failure and death. ICD implantation for primary prevention should be considered if patients (particularly the young) have any of the following high-risk features:

- Personal history of sudden cardiac death or out of hospital cardiac arrest (major risk factor)
- Spontaneous sustained ventricular tachycardia or ventricular fibrillation (major risk factor)
- Family history of premature death in a first-degree relative possibly caused by HCM
- Unexplained syncope
- Nonsustained ventricular tachycardia during Holter monitoring
- Substantial septal hypertrophy (>30 mm)
- Abnormal blood pressure response during exercise

- Increased delayed gadolinium enhancement on cardiac magnetic resonance imaging is suggested in some recent studies as a marker of increased sudden cardiac death risk

REFERRAL

- Surgical treatment (septal myectomy involving resection of the basal septum) is now the gold standard for relieving outflow tract obstruction in patients with large outflow gradient (≥50 mm Hg) and moderate to severe symptoms unresponsive to medical therapy. The risk for sudden death from arrhythmias is not altered by surgery. When this operation is performed by experienced surgeons in tertiary referral centers, the operative mortality rate is <1%, and many patients are able to achieve near-normal exercise capacity after surgery. Mitral valvuloplasty or plication in combination with myectomy may be necessary in <5% of patients. Risks of surgery include AV nodal block, ventricular septal defect, and aortic regurgitation (AR).
- Alcohol septal ablation is a nonsurgical alternative to reduce the size of the interventricular septum. This can be done in patients with HCM refractory to pharmacologic treatment, particularly in those who are not candidates for myectomy due to high surgical risk or patient preference. This technique involves the injection of ethanol in a septal perforator branch of the left anterior descending coronary artery (Fig. E4), producing a controlled myocardial infarction of the interventricular septum, and thereby reducing septal mass and consequently the left ventricular outflow tract gradient. This method may lead to improvement in both subjective and objective measures of exercise capacity, but results are not as effective as surgery because they are associated with a high incidence of heart block, requiring permanent pacing in approximately 25% of patients, and/or recurrence of obstruction and symptoms. This should be done only at centers with experienced operators.
- Refractory end-stage heart failure symptoms can be treated with left ventricular assist device, biventricular assist device, or heart transplant.

PEARLES & CONSIDERATIONS

COMMENTS

- Clinical screening of first-degree relatives with two-dimensional echocardiography and ECG is indicated. Starting at the age of 12, periodic screening at 12- to 18-month intervals is recommended for children of patients with HCM and in competitive athletes. Periodic screening of first-degree adult family members not in competitive athletics is recommended at 5-yr intervals because hypertrophy may not be detected until the sixth decade of life. If the index patient does not have a definite pathogenic mutation, then genetic testing of relatives is not indicated.
- Genetic counseling and screening (Fig. E5, Table 1) is recommended in first-degree relatives of patients with HCM. Genetic screening of first-degree relatives can refine or eliminate the need for periodic clinical screening. At least 13 genes are known to cause HCM, among them: Cardiac myosin binding protein-C, beta-myosin heavy chain, troponin T, troponin I, alpha tropomyosin, actin regulatory light chain, and essential light chain. Clinical predictors of positive genotype, such as the presence of ventricular arrhythmias, age at diagnosis, degree of left ventricular wall hypertrophy, and family history of HCM, may aid in patient selection for genetic testing and increase the yield of cardiac sarcomere gene screening. Currently a mutation can be identified in 40% to 60% of all cases, sporadic or familial.
- All HCM patients who wish to become pregnant should be given prenatal counseling about the risk of transmission (about 50%) to their offspring and should be followed at a tertiary care center that specializes in high-risk pregnancies. Most patients with HCM tolerate pregnancy well due to the higher circulating blood volume.
- The mortality rate in HCM is approximately 1% to 2% per yr.
- About one third of HCM patients will not have a resting or labile outflow gradient (i.e., nonobstructive form of HCM), but it is important to note that lethal ventricular arrhythmias can occur in the absence of obstruction or symptoms.
- Myocardial fibrosis is a hallmark of hypertrophic cardiomyopathy. Biomarkers of collagen metabolism such as serum C-terminal propeptide of type I procollagen (PICP) are significantly higher in mutation carriers without left ventricular hypertrophy and in subjects with overt hypertrophic cardiomyopathy than in controls, indicating that a probiotic state precedes the development of hypertrophy of fibrosis identifiable with cardiac MRI.

TABLE 1 Proposed Clinical Family Screening Strategies with Echocardiography or Cardiovascular Magnetic Resonance (and 12-Lead Electrocardiography) for Detection of HCM with Left Ventricular Hypertrophy*

Age <12 yr
Optional unless:
Malignant family history of premature death from HCM, or other adverse complications
Competitive athlete in an intense training program
Onset of symptoms
Other clinical suspicion of early left ventricular hypertrophy
Age 12-21 yr†
Every 12-18 months
Age >21 yr
Imaging at onset of symptoms, or possibly at 5-yr intervals at least through midlife; more frequent intervals for imaging are appropriate in families with malignant clinical course or history of late-onset HCM

*In family members who had not undergone genetic testing, or in whom testing was unresolved or indeterminant.
†Age range takes into consideration individual variability in achieving physical maturity, and in some patients, screening may be justified at an earlier age; initial evaluation should be performed no later than early pubescence.

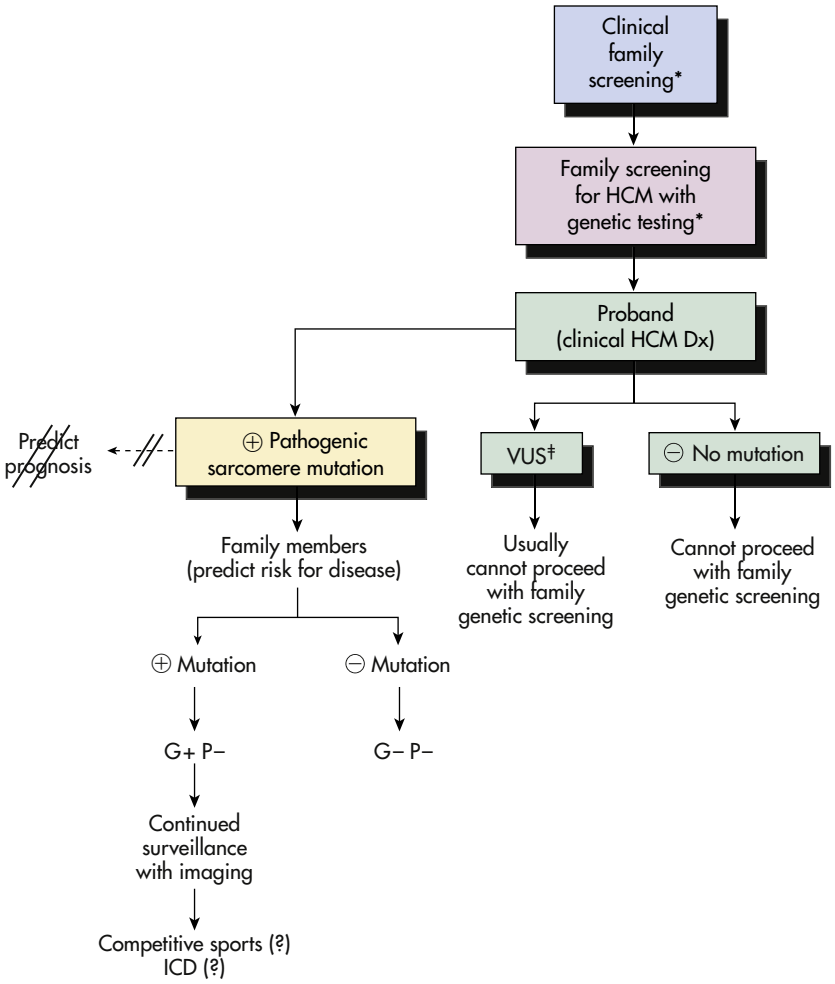

FIG. E5 Role of genetic testing in family screening strategies in hypertrophic cardiomyopathy *(HCM).* Some form of family screening for HCM in family members of the proband is universally recommended. The preferred first option (*) for clinical testing family members is usually with cardiac imaging and electrocardiography to identify phenotype-positive relatives. The predominant role for genetic testing in this setting is to identify those family members who are at risk for developing disease who do not have left ventricular (LV) hypertrophy. This strategy is initiated by successfully genotyping the proband with a clinically expressed HCM phenotype. Failure to identify the causative mutation in the proband is an indeterminate result that provides no useful information and precludes predictive testing in family members. The likelihood of obtaining a positive test result in the proband is less than 50%, insofar as all genes causing HCM have not yet been identified. Furthermore, many of the detected mutations will not be judged to be pathogenic, thereby eliminating substantially more than 50% of families from the option of genotyping for identification of relatives at risk for HCM. Accordingly, the genetic test results in the proband will be actionable in terms of family screening in only a minority of cases. *Dx,* Diagnosis; *G+ P–,* genotype-positive, phenotype-negative; *G– P–,* genotype-negative, phenotype-negative; *ICD,* implantable cardioverter-defibrillator; *VUS,* variant of uncertain significance. BASIC INFORMATION

DEFINITION

Restrictive cardiomyopathy refers to either an idiopathic or a secondary myocardial disorder (in the absence of ischemic, hypertensive, valvular, or congenital heart disease) characterized by restrictive filling (Fig. E1), normal or reduced left ventricular (LV) and right ventricular (RV) volumes, and normal or near normal systolic LV and RV function. Pathophysiologically, the myocardium is abnormally stiff, resulting in decreased compliance, abnormal relaxation in diastole, and increased filling pressures leading to enlarged left atria.

SYNONYMS

Idiopathic restrictive cardiomyopathy
Infiltrative cardiomyopathy

ICD-10CM CODES	
D86.XX	Sarcoidosis-related codes
E83.11X	Hemochromatosis-related codes
E85.X	Amyloidosis-related codes
I42.5	Other restrictive cardiomyopathy
I42.8	Other cardiomyopathies
I43.1	Cardiomyopathy in metabolic diseases
I42.9	Cardiomyopathy, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- A relatively uncommon cardiomyopathy, accounting for 5% of all primary myocardial diseases.
- Most frequently caused by amyloidosis or myocardial fibrosis (following open heart surgery, transplantation or radiation).
- Patients classified as having "idiopathic" restrictive cardiomyopathy may have mutations in the gene for cardiac troponin I, and restrictive cardiomyopathy may represent an overlap with hypertrophic cardiomyopathy in many familial cases.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Restrictive cardiomyopathy presents with symptoms of progressive left-sided and right-sided heart failure:

- Fatigue, weakness (caused by low output as patients are unable to augment cardiac output by increasing heart rate without compromising ventricular filling).
- Progressively worsening exercise intolerance and dyspnea.
- Anginal chest pain can be seen (particularly in patients with amyloidosis) from myocardial compression of small coronaries.
- Palpitations (atrial fibrillation is common), dizziness or syncope (from orthostasis, heart block, or malignant arrhythmia).
- Edema, ascites, hepatomegaly, distended neck veins (from elevated right heart pressures).
- Kussmaul sign may be present (rise, or failure to fall, of the jugular veins on inspiration).
- On auscultation: Murmurs of mitral or tricuspid regurgitation may be heard; an S3 may be present.
- Apical impulse may be palpable (can help distinguish it from constrictive pericarditis) and nondisplaced.

ETIOLOGY

Disease may be classified according to pathophysiologic processes:

- Infiltrative:
  1. Amyloidosis (most common overall): The main types include AA, AL, Aß (ß amyloid), and ATTR (transthyretin-mutated or wild type [commonly known as senile systemic])
  2. Sarcoidosis (more commonly causing a dilated cardiomyopathy with regional wall motion abnormalities)
- Noninfiltrative:
  1. Idiopathic (familial subtypes may have genetic overlap with hypertrophic cardiomyopathy)
  2. Scleroderma
  3. Diabetic cardiomyopathy
  4. Pseudoxanthoma elasticum
- Storage diseases:
  1. Hemochromatosis (more commonly associated with a dilated cardiomyopathy)
  2. Glycogen or other storage diseases (Gaucher, Hurler, Fabry—all rare)
- Endomyocardial:
  1. Endomyocardial fibrosis
  2. Hypereosinophilic syndrome (Loeffler syndrome)
- Carcinoid heart disease
- Radiation
- Metastatic cancers
- Drug related (anthracyclines, serotonin, ergotamine, busulfan, methysergide)

DIAGNOSIS

The diagnosis of idiopathic or primary restrictive cardiomyopathy is rare and is a diagnosis of exclusion.

DIFFERENTIAL DIAGNOSIS

- Constrictive pericarditis (see Table E1)
- Valvular dysfunction (especially aortic stenosis)
- Hypertrophic cardiomyopathy
- Hypertensive heart disease

WORKUP

- Complete blood count with differential (to identify eosinophilia), iron studies, serum renal function studies, chest x-ray, ECG, echocardiogram
- Right and left heart catheterization, magnetic resonance imaging, and computed tomography (in select cases)
- Aspiration biopsy of subcutaneous fat to detect amyloidosis
- Endomyocardial biopsy if diagnostic confirmation needed
- Brain natriuretic peptide (BNP) serum levels (>400 pg/ml): There are data suggesting that BNP levels are markedly elevated in restrictive cardiomyopathy but near normal in constrictive pericarditis, most likely resulting from the lack of myocardial stretching in constriction that is required for BNP release
- Genetic testing, including testing for transthyretin mutation in amyloidosis

IMAGING STUDIES

- Chest x-ray:
  1. Ranges from normal cardiomediastinal silhouette to moderate cardiomegaly (primarily because of biatrial enlargement).
  2. Evidence of heart failure may be present.
  3. Presence of pericardial calcification favors alternative diagnosis of constrictive pericarditis.
- ECG:
  1. Nonspecific ST-T wave abnormalities are the most common finding. Voltage may be low in infiltrative etiologies such as amyloidosis.
  2. Frequent atrial and ventricular ectopy are often present. Atrial fibrillation may be present.
  3. High-degree atrioventricular block, intraventricular conduction delay may be seen in advanced cases.
- Echocardiogram (Fig. 2):
  1. Biatrial enlargement almost always present.
  2. Wall thickness depends on etiology; often thickened in infiltrative disease.

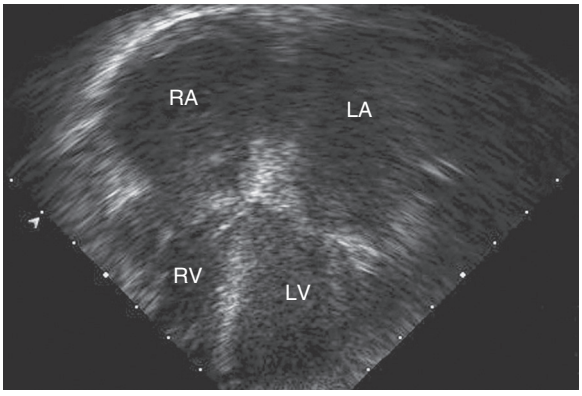

FIG. 2 Echocardiogram of a patient with restrictive cardiomyopathy. The optical four-chamber view shows the markedly enlarged right and left atria, compared to the normal-sized left and right ventricular chambers. *LA,* Left atrium; *LV,* left ventricle; *RA,* right atrium; *RV,* right ventricle. (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.)

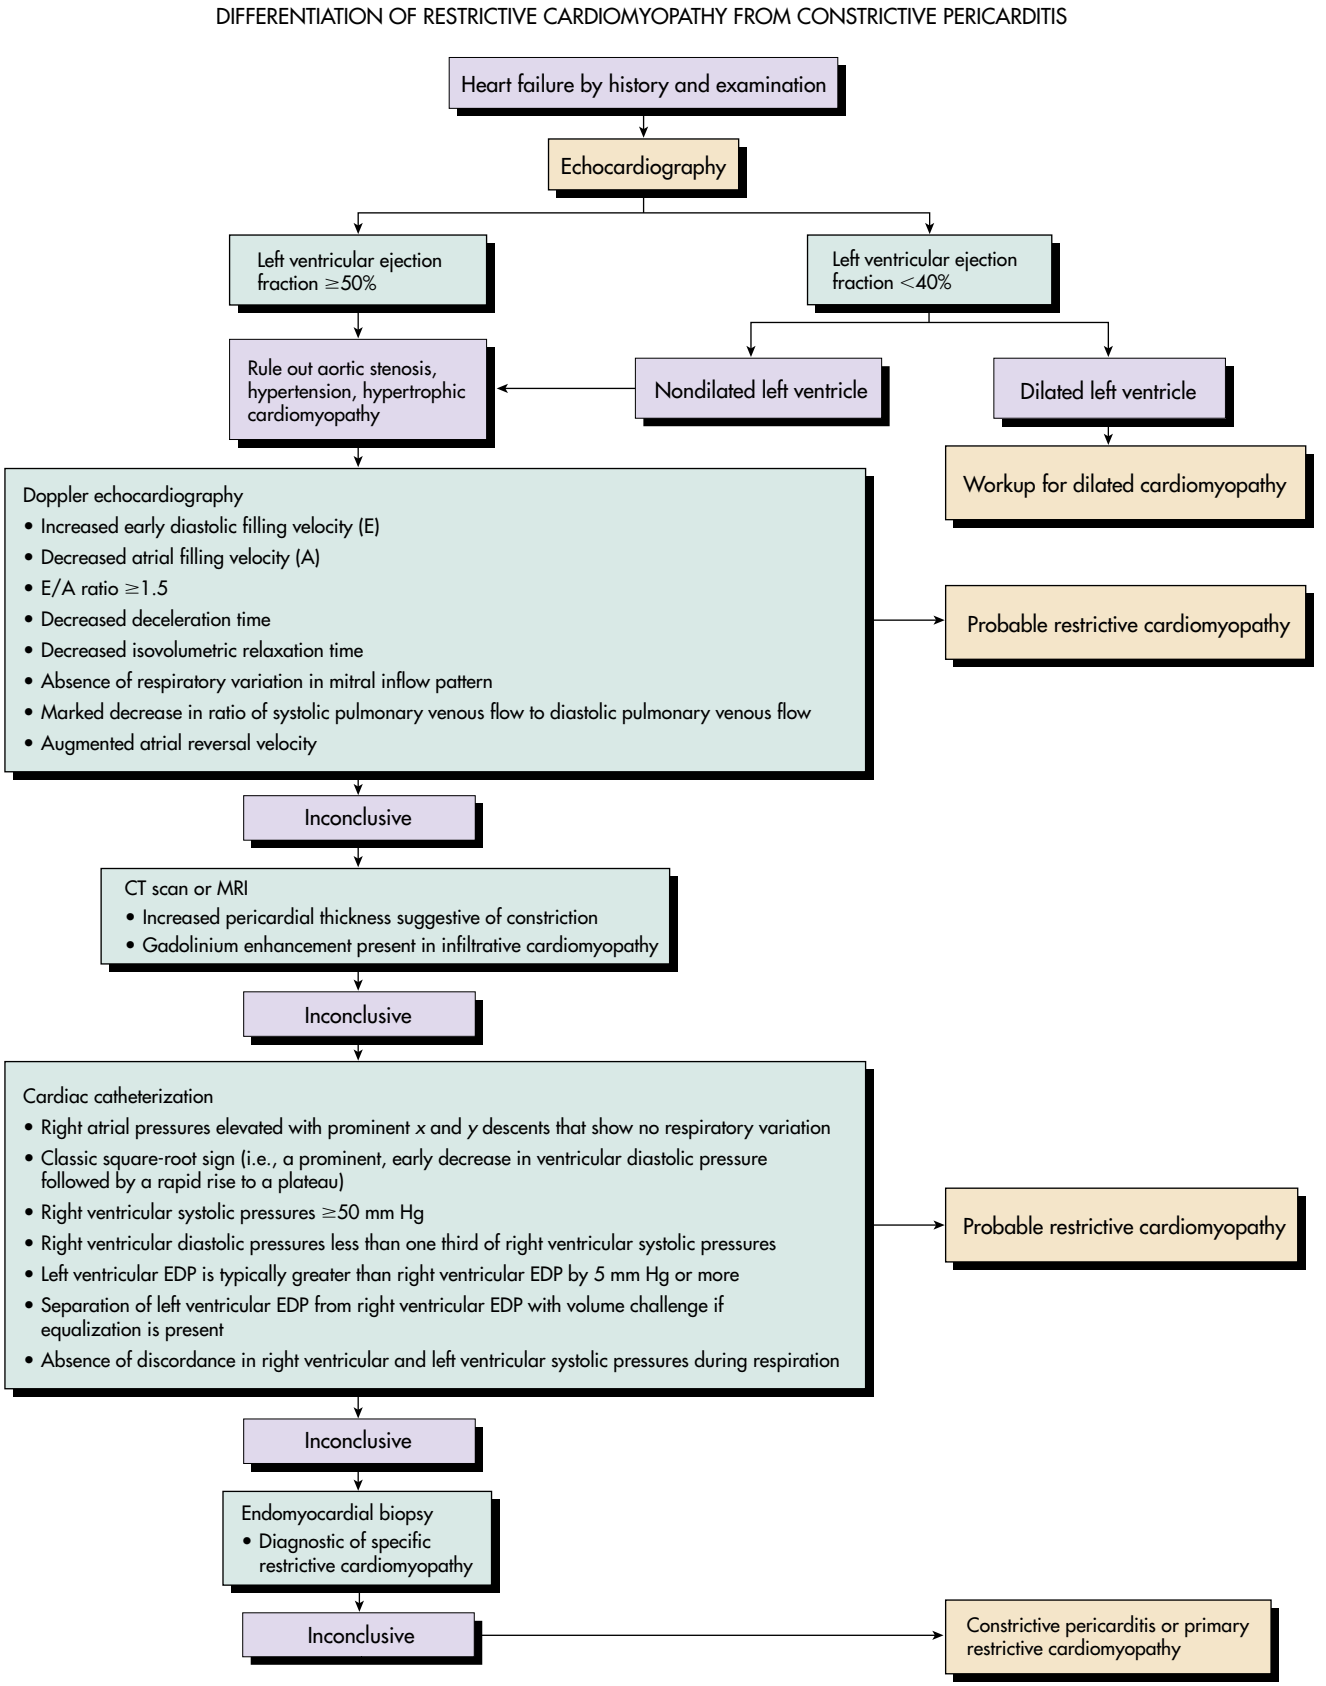

FIG. 3 Differentiation of restrictive cardiomyopathy from constrictive pericarditis. *CT,* Computed tomography; *EDP,* end-diastolic pressure; *MRI,* magnetic resonance image. (From Pereira NL, Dec GW: Restrictive and infiltrative cardiomyopathies. In Crawford MH et al: *Cardiology,* Philadelphia, 2010, Elsevier.)

3. Myocardial appearance may be altered (speckled pattern with apical sparing suggestive of amyloidosis).
4. Ventricular chamber sizes and systolic function are often normal or reduced.
5. Echo Doppler shows evidence of diastolic dysfunction. Tissue Doppler demonstrates low mitral annular velocities.

- Cardiac catheterization:
  1. Characteristic hemodynamic findings are a dip and plateau, or square-root sign, in the left ventricular tracing where a deep and rapid decline in ventricular pressure at the onset of diastole is immediately followed by rapid rise and plateau in early diastolic phase.
  2. To distinguish restrictive cardiomyopathy from constrictive processes (Fig. 3):
     a. Constrictive: Usually involves both ventricles and leads to equalization of diastolic pressures between all four cardiac chambers to within 5 mm Hg. There is discordance in RV and LV pressures generated during inspiration, which is due to increased ventricular interdependence and decreased left atrial filling (caused by a decreased gradient in inspiration between the pulmonary veins, which are outside the constrictive process and the left atrium).
     b. Restrictive cardiomyopathy: Impairs the left ventricle more than the right, often with left-sided end-diastolic pressures of 5 mm Hg greater than the right. The presence of increased pulmonary arterial systolic pressures is also suggestive of restrictive disease. Simultaneous RV and LV pressure tracings demonstrate concordant patterns during the respiratory cycle.
- Cardiac computed tomographic scan may be helpful to identify a thickened and calcified pericardium, consistent with constrictive pericarditis.
- Cardiac magnetic resonance imaging (CMRI) may also be useful to distinguish restrictive cardiomyopathy from constrictive pericarditis (thickness of the pericardium greater than 4 mm in the latter). CMRI is particularly helpful in the diagnosis of the amyloid or sarcoid variants and may have value in other variants as well. Late gadolinium enhancement can be seen with infiltrative diseases.
- Technetium pyrophosphate bone scintigraphy is useful in diagnosis of transthyretin cardiac amyloidosis and differentiates it from light chain amyloidosis.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Congestive symptoms may respond to dietary sodium restriction (<2 g/day).

ACUTE GENERAL Rx

Treatment of volume overload and heart failure symptoms with diuretic therapy.

CHRONIC Rx

- Treatment involves management of the underlying disease if it exists:
  1. Hemochromatosis may respond to repeated phlebotomy and iron chelators to decrease iron deposition in the heart.
  2. Sarcoidosis may respond to corticosteroid therapy.
  3. Primary amyloidosis may respond to chemotherapy (high-dose melphalan with autologous stem cell therapy or bortezomib-based regimens). ATTR may be treated with liver transplant or other promising novel therapeutic agents that are currently being tested in clinical trials.
  4. Eosinophilic cardiomyopathy may respond to corticosteroid and cytotoxic drugs.
  5. There is no effective therapy for other causes of restrictive cardiomyopathy.
- Overall, the goal of treatment is to reduce symptoms by decreasing filling pressures while preserving cardiac output. Since there is currently no drug available to specifically act on myocardial relaxation, therapy centers on low-dose diuretics to lower the preload.
- Beta-blockers or calcium channel blockers have not been demonstrated to improve symptoms or alter the course of disease. Must be careful not to decrease HR too far, as this will affect cardiac output (CO = HR × stroke volume).
- ACE inhibitors (or angiotensin receptor blockers [ARBs]) and vasodilators should be avoided in patients with amyloidosis as they are poorly tolerated. Even small doses can trigger profound hypotension (probably due to associated autonomic neuropathy). Adequate preload is necessary for LV filling and ultimately cardiac output.
- Atrial fibrillation is common and patients with it or with a history of embolization should be anticoagulated. Tachycardia (of any cause) is poorly tolerated and a common cause of decompensation. Rate control is of paramount importance. Cardioversion in case of rapid atrial fibrillation should be considered. Of note, digoxin should be used with caution as it is potentially arrhythmogenic (particularly in patients with amyloidosis).
- Fibrosis of the cardiac conduction system may result in complete heart block presenting as dizziness or syncope (especially in amyloidosis) and pacemaker implantation may be required. The course of restrictive cardiomyopathy is variable and depends on the underlying etiology. Death usually results from heart failure or arrhythmias, and interventions aimed at addressing these are recommended.
  1. For the amyloid variant, an implantable cardiac defibrillator offers little prophylactic benefit beyond the ability to pace because the cause of sudden cardiac death is usually electromechanical disassociation.

DISPOSITION

Prognosis varies with the etiology of the cardiomyopathy but is poor overall as disease is rarely detected before advanced stages.

REFERRAL

Cardiac transplantation can be considered in patients with refractory symptoms and idiopathic or familial restrictive cardiomyopathies.

Restrictive Cardiomyopathy (Patient Information)

AUTHOR: **Nathan Riddell, MD**

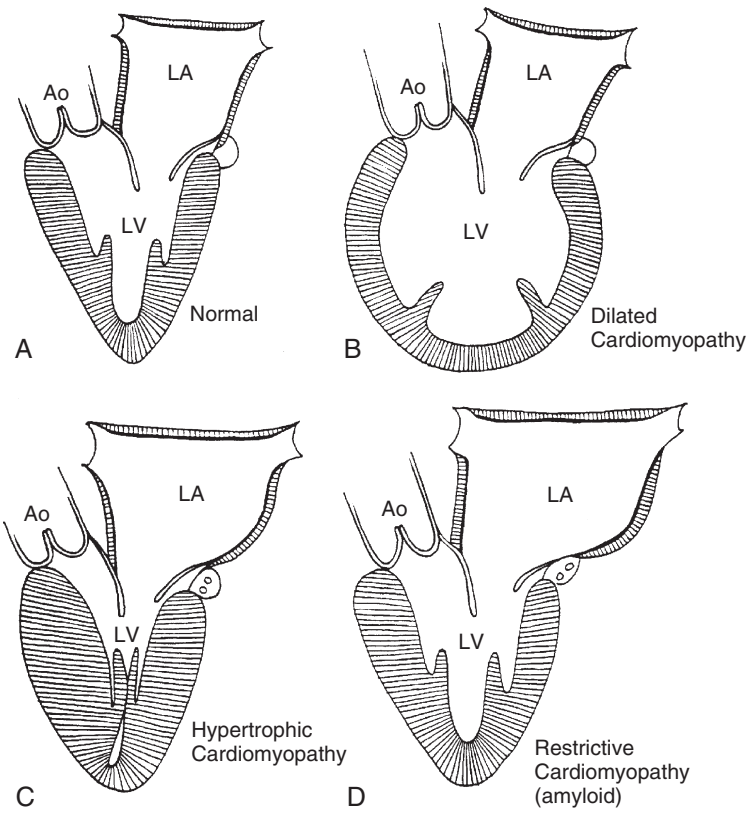

FIG. E1 Cardiomyopathies. A, Normal. **B,** Dilated. **C,** Hypertrophic. **D,** Restrictive. *Ao,* Aorta; *LA,* left atrium; *LV,* left ventricle. (Modified from Roberts WC, Ferrans VJ: Pathologic anatomy of the cardiomyopathies. *Hum Pathol* 6:289-342, 1975.)

TABLE E1 Differentiation between Restrictive Cardiomyopathy and Constrictive Pericarditis

Type of Evaluation	Restrictive Cardiomyopathy	Constrictive Pericarditis
Physical examination	Kussmaul sign present Apical impulse may be prominent Regurgitant murmurs are common	Kussmaul sign may be present Apical impulse usually not palpable Pericardial knock may be present Pulsus paradoxus may be present
Electrocardiography	Low QRS voltage (especially in amyloidosis) Pseudoinfarction pattern Bundle branch blocks AV conduction disturbances Atrial fibrillation	Low QRS voltage Repolarization abnormalities
Chest radiography		Calcification of the pericardium may be present
Echocardiography	Marked enlargement of the atria Increased wall thickness (especially in amyloidosis) Valvular thickening (especially in hypereosinophilia)	Atria usually of normal size Normal wall thickness Pericardial thickening may be seen
Doppler echocardiography	Restrictive mitral inflow (dominant E wave with short deceleration time) No significant variation of transvalvular velocities with respiration (<10%) Reversal of forward flow in hepatic veins during inspiration Low tissue Doppler velocities	Restrictive mitral inflow (dominant E wave with short deceleration time) Increased velocity of RV filling and decreased velocity of LV filling with inspiration; opposite with expiration; variation in velocity exceeds 15% Reversal of forward flow in hepatic veins during expiration Increased septal tissue Doppler velocities with below normal lateral velocities
Cardiac catheterization	Prominent atrial x and y descents (w sign) Dip-and-plateau appearance of ventricular diastolic pressure Diastolic pressures increased but not equalized (LV diastolic pressure higher than RV diastolic pressure)	Prominent atrial x and y descents (w sign) Dip-and-plateau appearance of ventricular diastolic pressure Increase and equalization of diastolic pressures Discordance of RV and LV peak systolic pressures (with inspiration, RV systolic pressure increases and LV systolic pressure decreases)
Endomyocardial biopsy	May reveal specific cause of restrictive cardiomyopathy	No specific findings on endomyocardial biopsy Pericardial biopsy may reveal abnormality
Computed tomography, magnetic resonance imaging	Late gadolinium myocardial enhancement in certain conditions	Pericardial thickening >4 mm
Laboratory testing	BNP is elevated	BNP may be normal to slightly elevated

AV, Atrioventricular; *BNP,* brain natriuretic peptide; *LV,* left ventricular; *RV,* right ventricular.

BASIC INFORMATION

DEFINITION

- The term *cardiorenal syndrome (CRS)* refers to disorders of the heart and kidneys in which acute or chronic dysfunction in one organ may induce acute or chronic dysfunction in the other.
- According to the recent definition proposed by the consensus conference of the Acute Dialysis Quality Initiative Group (September 2008), CRS has been used to define different clinical conditions in which heart and kidney dysfunction overlap.
- There are five types of CRS (Fig.E1).
- This section focuses on CRS types 1 and 2.

SYNONYM

CRS

ICD-10CM CODES

I13	Hypertensive heart and chronic kidney disease
I13.0	Hypertensive heart and chronic kidney disease (unspecified or stages 1-4) with heart failure
I13.2	Hypertensive heart and chronic kidney disease (stage 5 or ESRD) with heart failure

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of congestive heart failure (CHF) in the United States exceeded 6.2 million people from 2013 to 2016.
- Chronic kidney disease (CKD) is present in 20% to 67% of patients with CHF.
  1. Women, the elderly, Caucasians, and patients with diabetes mellitus or treatment-resistant hypertension have an increased incidence of CHF.
  2. In general, mortality is increased in patients with HF and reduced glomerular filtration rate (GFR).
  3. CKD patients have an increased risk of atherosclerotic heart disease and HF.
  4. Cardiovascular disease is responsible for up to 50% of deaths in patients with CKD.
- 20% to 30% of patients treated for acute or chronic CHF will develop acute kidney injury (AKI).
  1. In patients with acute CHF, the severity of AKI is increased with decreased left ventricular systolic function and baseline CKD.
  2. Only 9% of patients hospitalized with acute HF in the Acute Decompensated Heart Failure National Registry database (ADHERE) had normal renal function with GFR >90 ml/min per 1.73 m^2 on admission.
- Patients with acute HF experienced the highest frequency of CRS, but the impact on mortality was greatest in patients who developed CRS in the setting of cardiac surgery.

Cardiorenal syndrome (CRS) general definition:
A pathophysiologic disorder of the heart and kidneys whereby acute or chronic dysfunction in one organ may induce acute or chronic dysfunction in the other organ

CRS type I (acute cardiorenal syndrome)
Abrupt worsening of cardiac function (e.g., acute cardiogenic shock or decompensated congestive heart failure) leading to acute kidney injury

CRS type II (chronic cardiorenal syndrome)
Chronic abnormalities in cardiac function (e.g., chronic congestive heart failure) causing progressive and permanent chronic kidney disease

CRS type III (acute renocardiac syndrome)
Abrupt worsening of renal function (e.g., acute kidney ischemia or glomerulonephritis) causing acute cardiac disorder (e.g., heart failure, arrhythmia, ischemia)

CRS type IV (chronic renocardiac syndrome)
Chronic kidney disease (e.g., chronic glomerular disease) contributing to decreased cardiac function, cardiac hypertrophy, and/or increased risk of adverse cardiovascular events

CRS type V (secondary cardiorenal syndrome)
Systemic condition (e.g., diabetes mellitus, sepsis) causing both cardiac and renal dysfunction

FIG. E1 Definitions of cardiorenal syndromes. (From Ronco C et al: Cardiorenal syndrome, *J Am Coll Cardiol* 52(19):1527–1539, 2008.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute/subacute decompensated heart failure (ADHF)
  1. Clinical symptoms
     a. Dyspnea with exertion or at rest
     b. Orthopnea
     c. Paroxysmal nocturnal dyspnea
     d. Right upper quadrant pain
  2. Vital signs
     a. Sinus tachycardia
     b. Hypertension or hypotension
     c. Elevated respiratory rate
     d. Narrow pulse pressure
     e. Pulsus alternans: Poor prognostic indicator
  3. Physical exam findings
     a. Elevated jugular venous pressures
     b. Peripheral edema
     c. Third heart sound (S3)
     d. Respiratory crackles
     e. Abdominal ascites
     f. Hepatomegaly and splenomegaly
- Chronic heart failure
  1. Clinical symptoms
     a. Dyspnea
     b. Fatigue
     c. Anorexia is a poor prognostic feature
  2. Vital signs
     a. Hypotension may be present with a low cardiac output state; sinus tachycardia may be absent
     b. Physical exam findings
        (1) Like findings in ADHF, but rales may be absent, reflecting the rapidity of the collection of fluid. In chronic HF, the pulmonary vasculature may store large alveolar fluid volumes instead of total body intravascular volume
- Findings of HF will be associated with laboratory findings of kidney disease (discussed later). In extreme cases, physical exam findings of severe kidney disease such as asterixis, uremic frost, uremic smell, and uremic pericarditis may be present

ETIOLOGY

The major mechanism of acute CRS is believed to be systemic congestion leading to increased renal venous pressure that in turn reduces renal perfusion. The etiology of CRS can be divided into various categories (Figs. E2, E3, and E4):

- Increased renal venous pressure.
  1. Secondary to elevated central venous pressure or elevated intraabdominal pressure.
  2. Frequency of worsening kidney function is lowest in patients with central venous pressure (CVP) <8 mm Hg.
  3. GFR increase may occur following diuretic therapy, which is most likely mediated by a reduction in renal venous pressure and/or a reduction in right ventricular dilation.
- Reduced renal perfusion.
  1. Common cause of CRS type 1 (acute CHF results in AKI).

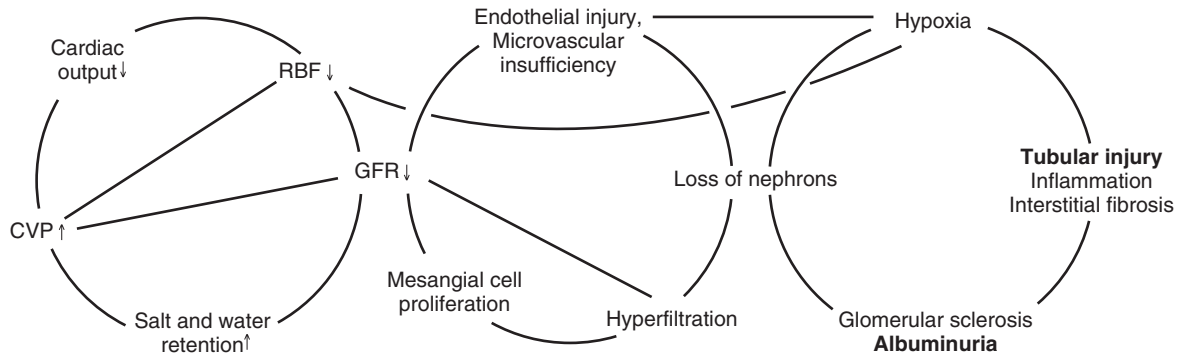

FIG. E2 Integrated pathways of the cardiorenal syndrome in heart failure. *CVP,* Central venous pressure; *GFR,* glomerular filtration rate; *HF,* heart failure; *RBF,* renal blood flow. (From Damman K et al: The cardiorenal syndrome in heart failure, *Prog Cardiovasc Dis* 54:144-153, 2011.)

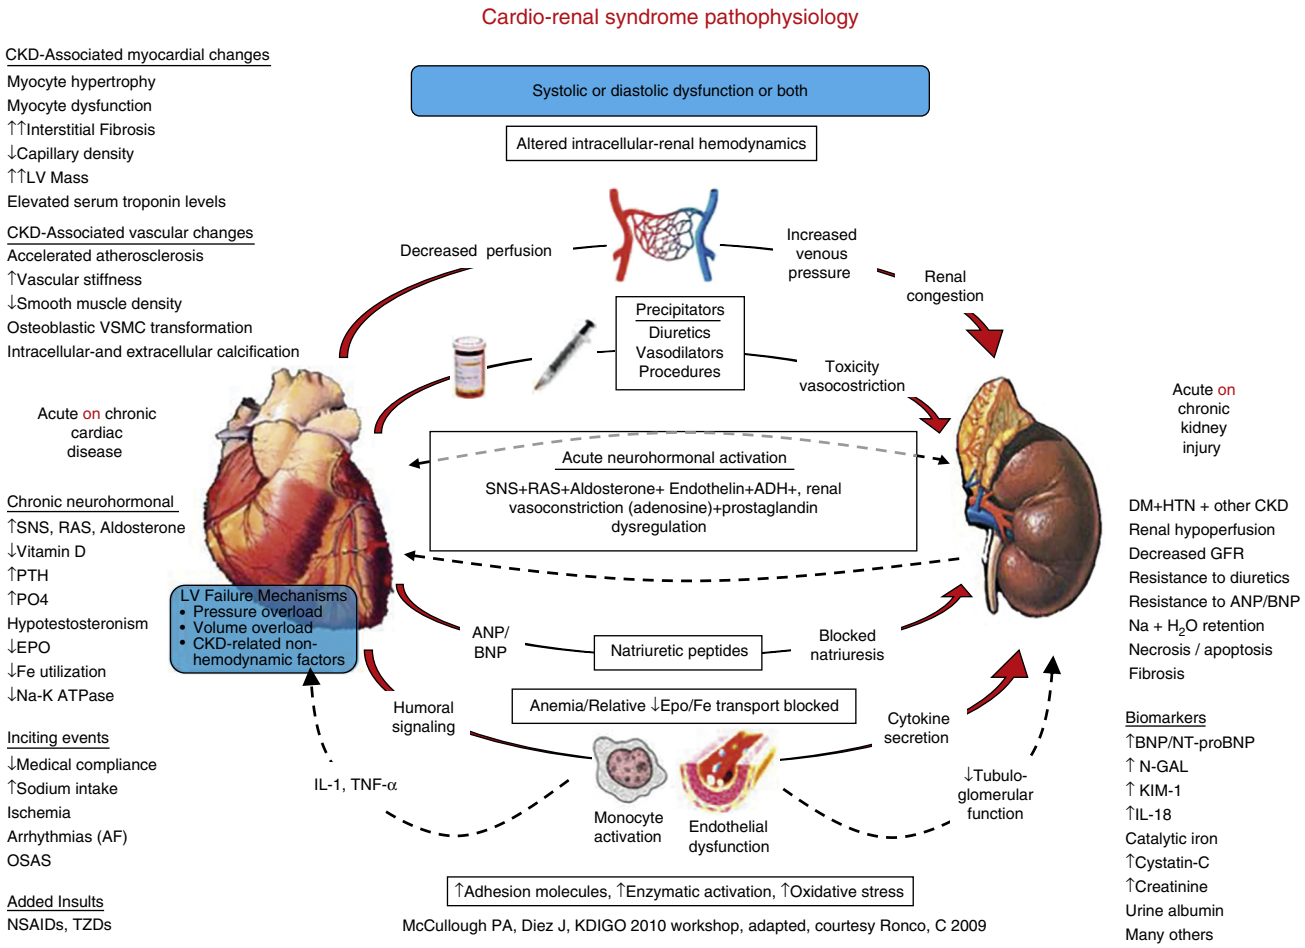

FIG. E3 Pathophysiology of type 1 cardiorenal syndrome or worsening renal function after hospitalization for acutely decompensated HF. *ADH,* Antidiuretic hormone; *AF*, atrial flutter; *ANP/BNP*, atrial natriuretic protein/B-type natriuretic peptide; *BNP*, B-type natriuretic peptide; *CKD*, chronic kidney disease; *DM*, diabetes mellitus; *EPO*, erythropoietin; *GFR*, glomerular filtration rate; *HTN*, hypertension; *IL*, interleukin; *KIM*, kidney injury molecule; *LV*, left ventricular; *N-GAL*, neutrophil gelatinase-associated lipocalin; *NSAIDs*, nonsteroidal antiinflammatory drugs; *NT-proBNP*, N-terminal pro B-type natriuretic peptide; *OSAS*, obstructive sleep apnea syndrome; *PTH*, parathyroid hormone; *RAS*, renin-angiotensin system; *SNS*, sympathetic nervous system; *TNF*, tumor necrosis factor; *TZDs*, thiazolidinediones; *VSMC*, vascular smooth muscle cell. (From Herzog CA et al: Cardiovascular disease in chronic kidney disease: a clinical update from Kidney Disease: Improving Global Outcomes (KDIGO), *Kidney Int* 80:572, 2011.)

2. Loop diuretic therapy can reduce ventricular preload and reduce cardiac output by as much as 20%.

- Right ventricular dilation and dysfunction.
  1. Increases central venous pressure that increases renal venous pressure and reduces GFR.
  2. Right ventricular dilation and dysfunction reduce left ventricular filling and renal blood flow.
- Neurohormonal.
  1. Activation of the renin-angiotensin-aldosterone system, sympathetic nervous system, antidiuretic hormone, and endothelin-1 increases salt and water retention. Systemic vasoconstriction decreases renal perfusion.
  2. Activation of the above neurohormonal systems supersedes vasodilatory effects of natriuretic peptides, nitric oxide, prostaglandins, and bradykinin.

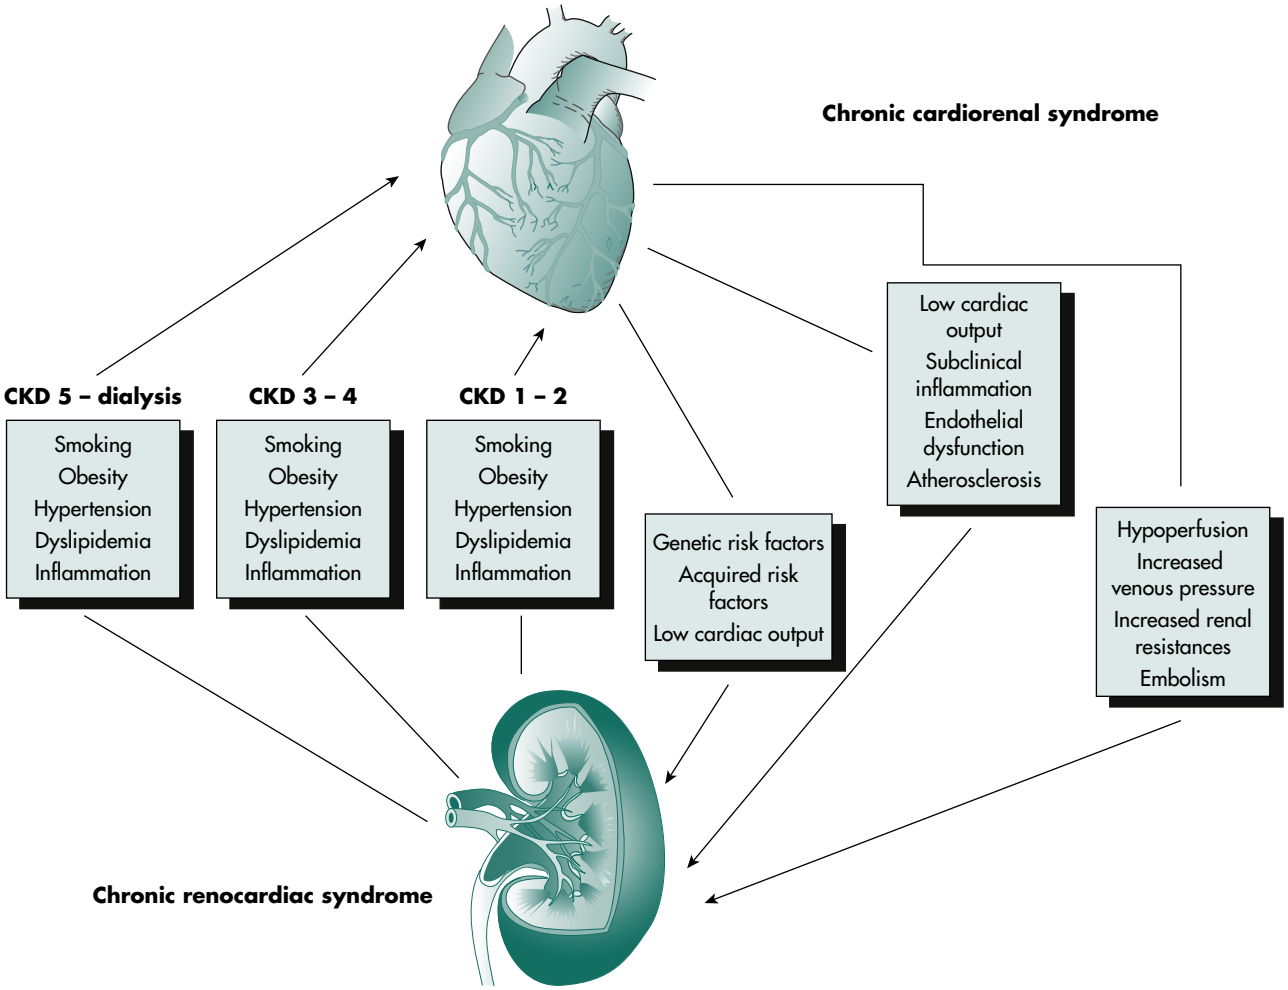

FIG. E4 Pathophysiology of type 2 cardiorenal syndrome. *CKD,* Chronic kidney disease. (Ronco C et al: *Critical care nephrology*, ed 3, Philadelphia, 2019, Elsevier.)

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Before establishing a diagnosis of CRS, rule out other causes of kidney failure
  1. Prerenal causes:
     a. Volume depletion (overdiuresis, gastrointestinal losses, or vomiting)
     b. Fluid overload states, excluding CHF (cirrhosis, nephrotic syndrome)
  2. Intrinsic renal disease:
     a. Acute tubular necrosis
     b. Glomerular disease: Nephrotic and nephritic syndromes
  3. Postrenal causes:
     a. Obstruction

WORKUP

- Medical history consistent with CHF symptoms including dyspnea, orthopnea, paroxysmal nocturnal dyspnea, edema, increasing abdominal girth, or weight gain. Laboratory results demonstrate signs of kidney injury.
- Diagnostic workup includes chest radiograph, echocardiogram, kidney ultrasound, and laboratory tests.

LABORATORY TESTS

- Serum creatinine:
  1. Patients with CRS had a mortality odds ratio of 1.48 for even mild increases in serum creatinine levels (0.3 to 0.5 mg/dl above baseline), with higher odds ratio for mortality with increases of serum creatinine >0.5 mg/dl
     a. For serum creatinine level increases of >0.5 mg/dl, the odds ratio for mortality increases to 3.22
- Glomerular filtration rate (GFR):
  1. Evaluation of GFR using estimated GFR (eGFR) or calculated GFR
- Blood urea nitrogen:
  1. Admission levels >43 mg/dl are associated with higher in-hospital mortality rate
- Brain natriuretic peptide (BNP):
  1. Initial admission values >480 pg/ml are associated with a 51% chance of death, hospital readmission, or an emergency department visit within 6 months versus levels <230 pg/ml
- It may be difficult to distinguish between CKD and impaired kidney function due to CRS, especially when prior renal function is unknown. Some patients have underlying CKD and CRS. Findings that support underlying CKD include significant proteinuria (>1000 mg/day), urine sediment with hematuria and/or pyuria, cellular casts, and/or small echogenic kidneys on ultrasound

IMAGING STUDIES

- Chest radiograph:
  1. May demonstrate signs of fluid overload, including pulmonary edema, effusions, or fluid in the fissures
- Echocardiogram:
  1. Determines presence of underlying systolic or diastolic dysfunction and/or significant valvular disease
- Kidney ultrasound:
  1. Kidney ultrasound can help distinguish between acute and chronic kidney disease and determine whether obstruction may be worsening kidney function

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Sodium and fluid restriction with sodium less than 2 g (87 mmol) daily is recommended for CHF patients
- Hemodialysis/ultrafiltration

1. Used when there is insufficient response to pharmacologic treatment or when pharmacologic agents are limited by hemodynamics or worsening laboratory values

- Left ventricular assist device/cardiac resynchronization therapy (CRT)
  1. Improves cardiac output by improving ejection fraction by 7% and HF symptoms in patients with New York Heart Association (NTHA) Class II to IV HF with left ventricular ejection fractions ≤35% and left bundle branch block with QRS duration >150 msec

ACUTE GENERAL Rx

No medical treatment directly improves GFR in the setting of CRS. Enhancing cardiac function may improve kidney function by alleviating any of the mechanisms of CRS listed.

- Diuretics:
  1. Extracellular fluid volume reduction improves the left ventricular Frank-Starling relationship.
  2. Reducing volume overload decreases central venous pressure, renal venous pressure, and right ventricular dilation. Consequently, right ventricular function and left ventricular performance improve.
  3. Twice-daily intravenous furosemide initiated at 2.5 times the daily oral furosemide equivalent dose is a recommended initial dosing strategy.
  4. High-dose intravenous bolus loop diuretic therapy improves cardiopulmonary congestion more effectively than low-dose loop diuretics. Continuous loop diuretic infusions are not more effective than frequently administered bolus loop diuretic regimens for fluid removal in non-oliguric patients.
  5. Diuretic resistance is frequently encountered. Common causes are inadequate dose of diuretic, nonadherence to the medical regimen, and/or high sodium intake. Pharmacokinetic factors include slow absorption of diuretic due to gut edema, impaired secretion of diuretic into the tubular lumen due to low renal plasma flow, CKD, hypoalbuminemia, hypotension, and antinatriuretic drugs.
  6. Combination diuretic regimes may optimize treatment (e.g., furosemide and metolazone).
- Blockade of the renin-angiotensin-aldosterone system:
  1. Angiotensin–converting-enzyme (ACE) inhibitors, angiotensin II receptor blockers, aldosterone receptor antagonists, and direct renin inhibitors
     a. Use limited by worsening kidney function, particularly if serum creatinine is greater than 2.5 mg/dl
     b. Permits reduced diuretic dosages
     c. Efficacy of anti-renin-angiotensin-aldosterone system therapy in the management of decompensated HF is well established, but its role in CRS is unproven
- Vasodilators:
  1. Nitroglycerin and nitroprusside
     a. Increase renal perfusion pressure by improving Frank-Starling relationships and cardiac output
- Inotropic agents:
  1. Dobutamine, dopamine, and milrinone
  2. Improve cardiac output and renal perfusion by vasodilation. Used to treat cardiogenic shock and low cardiac output states with normal blood pressure
  3. Dobutamine and milrinone may lower systemic blood pressure, limiting therapeutic efficacy
- Mechanical fluid removal such as extracorporeal ultrafiltration (UF) may be required to achieve control of fluid balance, particularly in patients resistant to diuretic therapy. UF removes plasma salt and water isotonically via convection through a highly permeable filter in an extracorporeal circuit. With slow continuous UF, the intravascular fluid volume remains stable as fluid shifts from the extravascular to intravascular space without inducing hypotension. UF may be indicated in highly refractory HF patients with diuretic resistance
- Sodium-glucose cotransporter-2 (SGLT-2) inhibitors may positively influence cardiovascular outcomes in patients with CKD. The EMPEROR heart failure trial will investigate the safety and efficacy of empagliflozin in patients with chronic HF and, respectively, preserved and reduced cardiac function

DISPOSITION

Based on improvements in heart failure and kidney function.

REFERRAL

Consultations by a cardiologist and nephrologist are recommended.

Carotid Artery Stenosis PTG

BASIC INFORMATION

DEFINITION

Carotid artery stenosis is narrowing of the carotid arterial lumen, typically as a result of atherosclerosis.

SYNONYM

Atherosclerotic disease of the carotid artery

ICD-10CM CODES

I65.29	Occlusion and stenosis of unspecified carotid artery
I65.21	Occlusion and stenosis of right carotid artery
I65.22	Occlusion and stenosis of left carotid artery
I65.23	Occlusion and stenosis of bilateral carotid arteries

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 2.2 to 8/1000 persons per yr
PREVALENCE: 11 to 77/100,000 persons; it is estimated that 5/1000 persons aged 50 to 60 yr and 100/1000 persons >80 yr have carotid stenosis >50%. (NOTE: The incidence of carotid artery stenosis is unknown as screening is not routine. However, the incidence of transient ischemic attack [TIA], a common presenting symptom of carotid stenosis, is well known.)
PREDOMINANT SEX AND AGE: Male:female ratio of 2:1; more common in whites than African Americans and Asians
PEAK INCIDENCE: Peak incidence is between 50 and 60 yr.
GENETICS: Multifactorial; twin studies (monozygotic versus dizygotic) suggest a familial influence.
RISK FACTORS: Hypertension, dyslipidemia, diabetes mellitus, and smoking are the four major risk factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Patients with carotid artery stenosis are often asymptomatic, but many either have a carotid bruit or experience a TIA.

- Carotid bruit: The presence of a carotid bruit is a better indicator of generalized atherosclerosis and is thus a better predictor of ischemic heart disease than future stroke.
- TIA: Carotid artery stenosis is classically heralded by ipsilateral transient monocular blindness (amaurosis fugax), contralateral numbness or weakness, contralateral homonymous hemianopsia, or aphasia.

ETIOLOGY

- Atherosclerosis (most common by far)
- Aneurysm
- Arteritis
- Carotid dissection
- Fibromuscular dysplasia
- Post-radiation necrosis
- Vasospasm

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Aneurysm, arteritis, and carotid dissection

WORKUP

Systematic history, examination, and diagnostic studies to assess for carotid stenosis and other risk factors of TIA and stroke. Carotid artery stenosis is responsible for approximately 10% of all ischemic strokes.

LABORATORY TESTS

CBC, comprehensive metabolic panel, fasting lipid profile, PT/international normalized ratio, APTT, HgA1C

IMAGING STUDIES

- Four imaging modalities are available for the evaluation of carotid artery stenosis (Table 1).
- Patients with transient ischemic attack or stroke should be evaluated for carotid artery stenosis via carotid duplex, magnetic resonance angiography, or computed tomography angiography. Conventional angiography may be obtained to confirm the degree of stenosis and plan for interventional (Fig. 1).
- The U.S. Preventive Services Task Force recommends against screening for asymptomatic carotid artery stenosis in the general adult population.
- Screening with carotid duplex may be considered in asymptomatic patients with carotid bruit, in those with multiple risk factors for atherosclerosis, or those with known atherosclerotic disease at other sites such as coronary artery disease, peripheral arterial disease, or abdominal aortic aneurysms.
- Patients identified to have >50% stenosis on carotid duplex may be re-imaged annually to assess progression and should have intensive medical management of vascular risk factors.

TREATMENT

ACUTE GENERAL Rx

- General medical therapy should be aimed at risk factor reduction. The major risk factors for carotid artery stenosis are hypertension, diabetes mellitus, dyslipidemia, and smoking (see "Stroke, Secondary Prevention").
- Antiplatelet therapy: Three antiplatelet options are available for patients with carotid artery stenosis: ASA, ASA plus dipyridamole, or clopidogrel.

TABLE 1 Imaging Modalities for Carotid Stenosis

Imaging Modality	Benefit	Drawback
Cerebral angiography	• Gold standard • Assesses plaque morphology • Assesses presence of collaterals	• Invasive • High cost • 4% incidence rate of complications • 1% incidence rate of serious complications or death
Carotid duplex	• Sensitive in detecting high-grade stenosis (>70%) • Less invasive • Lower cost	• Can be limited by body habitus • Technician dependent • Overestimates degree of stenosis • May not distinguish high grade stenosis from complete occlusion
Magnetic resonance angiography (MRA)	• Sensitive in detecting high-grade stenosis (>70%) • Less operator dependent	• Overestimates degree of stenosis • Cannot be performed in patients who are critically ill, unable to tolerate supine positioning, have pacemaker or other ferromagnetic hardware, or are claustrophobic* • Expensive • Takes much longer to obtain compared with other modalities
Computed tomography angiography (CTA)	• Sensitive for high-grade stenosis	• Contraindicated in patients with serum creatinine concentration >1.5 mg/dl • Uses ionizing radiation

*One study revealed that ~17% of patients are unable to tolerate MRA secondary to claustrophobia or are unable to lie still for procedure.

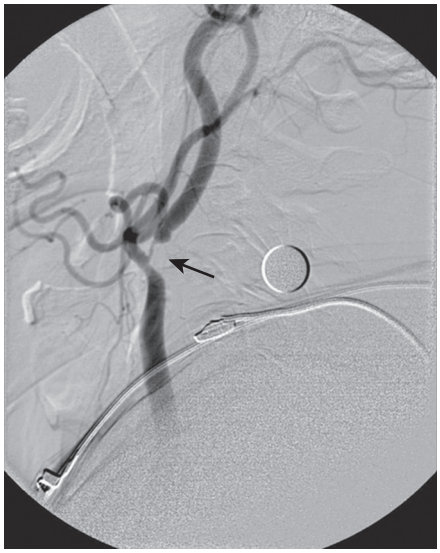

FIG. 1 Conventional angiography demonstrating severe stenosis of the internal carotid artery at the bifurcation.

NONPHARMACOLOGIC THERAPY

Carotid endarterectomy (CEA) and carotid angioplasty and stenting (CAS) (Fig. 2) are the two nonpharmacologic options available. The decision on which revascularization procedure to favor is dependent upon the presence or absence of symptoms, degree of stenosis, medical comorbidities, operative risk of the patient, and experience and outcomes data of the proceduralist. Factors associated with increased risk from carotid artery surgery are summarized in Table 2.

In a trial involving asymptomatic patients with severe carotid stenosis who were not at high risk for surgical complications, stenting was noninferior to endarterectomy with regard to the rate of the primary composite end point at 1 yr. In analyses that included up to 5 yr of follow-up, there were no significant differences between the study groups in the rates of nonprocedure-related stroke, all stroke, and survival.[1]

ASYMPTOMATIC CAROTID STENOSIS

The benefit of surgical revascularization of the carotids (CEA or CAS) in asymptomatic patients is not well established. In the U.S., more than 90% of carotid artery interventions are performed in asymptomatic patients, even though evidence suggests that up to 90% of these patients are undergoing an ultimately unnecessary and potentially harmful procedure. In contrast, the percentage of interventions performed for asymptomatic stenosis is approximately 60% in Germany and Italy, 15% in Canada and Australia, and 0% in Denmark.[2]

According to the most recent guidelines, revascularization procedures may be considered in asymptomatic patients with >70% stenosis if the anticipated perioperative risk is less than 3%, but surgery should only be recommended after considering medical comorbidities and life expectancy and after discussing the risks and benefits in detail with the patients. It is important to note that trials of CEA for asymptomatic carotid stenosis were performed prior to the era of aggressive medical management of vascular risk factors. Recently launched studies of asymptomatic carotid stenosis versus aggressive contemporary medical management will answer lingering questions from older studies.

SYMPTOMATIC CAROTID STENOSIS

In patients who have suffered a non-disabling ischemic stroke or TIA in the preceding 6 mo, surgical revascularization by CEA is recommended if the degree of carotid stenosis is severe (70% to 99%) and if the anticipated rate of perioperative stroke or mortality is <6%. The number needed to treat to prevent 1 stroke in 2 yr is 6.

In patients who have suffered a non-disabling ischemic stroke or TIA in the preceding 6 mo, and who have moderate carotid stenosis (50 to 69%), CEA is recommended based on an assessment of the patient's age, sex, and comorbidities. To prevent 1 stroke in 5 yr, 15 patients with moderate carotid stenosis would have to undergo CEA. Factors to consider in recommending CEA for patients with moderate symptomatic carotid stenosis are age, sex, and comorbidities. The NASCET trial, which studied the efficacy of CEA versus medical management, suggested that women experienced higher complication rates from CEA than men. However the CREST trial, which compared CEA to carotid stenting, did not find a sex-related outcome difference between the two interventions. It did find that patients older than 70 did better with CEA than with carotid stenting. All patients undergoing CEA should be started on aspirin (ASA; 81 or 325 mg daily) and a high dose statin before surgery. This therapy, along with blood pressure control and aggressive management of other vascular risk factors, should be continued indefinitely.

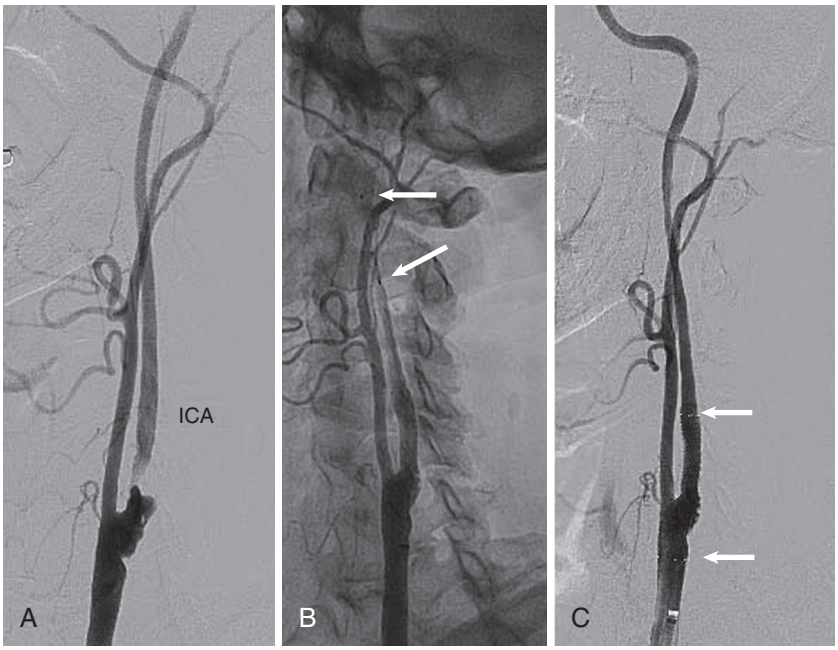

FIG. 2 Carotid stenting for symptomatic carotid stenosis. A, Stenosis at origin of left internal carotid artery. **B,** Stent deployed. Arrows indicate markers of embolic protection filter. **C,** Final angiogram with arrows indicating the margins of the stent. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.)

TABLE 2 Factors Associated with Increased Risk from Carotid Artery Surgery

Anatomic Criteria
High cervical or intrathoracic lesion
Previous neck surgery or radiation therapy
Contralateral carotid artery occlusion
Previous ipsilateral carotid endarterectomy
Contralateral laryngeal nerve palsy
Tracheostomy
Medical Comorbidities
Age >80 yr*
Class III or IV congestive heart failure
Class III or IV angina pectoris
Left main coronary disease
Two- or three-vessel coronary artery disease
Need for open heart surgery
Ejection fraction ≤30%
Recent myocardial infarction
Severe chronic obstructive lung disease

*The risk for a cerebrovascular accident (stroke) with carotid artery stent placement is increased, and the risk for myocardial infarction with carotid endarterectomy is increased.

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.

[1] Rosenfield K et al, for the ACT I Investigators: Randomized trial of stent versus surgery for asymptomatic carotid stenosis, *N Engl J Med* 374:1011-1020, 2016.

[2] Spence DJ, Naylor AR: Endarterectomy, stenting, or neither for asymptomatic carotid artery stenosis, *N Engl J Med* 374:1087-1088, 2016.

CAS can be an alternative to CEA in select patients considered to be at high surgical risk or with unfavorable neck anatomy for surgery.

CEA is preferred over CAS in older patients.

For patients undergoing CAS, dual antiplatelet therapy is recommended for a minimum of 30 days.

When feasible, early revascularization within 14 days after incident event should be undertaken unless there are definite contraindications. For patients undergoing early intervention, CEA is associated with lower periprocedural complication rate than CAS.

Surgical revascularization is not recommended in <50% stenosis, total occlusion, or in patients with major disabling strokes.

In patients who are considered high surgical risk for either CEA or CAS, the role of medical therapy alone compared with surgical revascularization is not well established.

DISPOSITION

Disposition and prognosis depend on several variables (Table 3): The degree of stenosis, the presence of symptoms, medication compliance, and the type of intervention (if any).

PEARLS & CONSIDERATIONS

The results of ongoing studies concerning the best treatment of patients with carotid artery stenosis may result in guideline changes.

SPECIAL CONSIDERATION

Some studies have shown that in patients with bilateral hemodynamically significant stenosis (>70%), blood pressure reduction resulted in worsened outcomes for stroke. These patients would likely be candidates for CEA.

Carotid artery occlusion (100% blockage), for which there is no routine treatment, was reexamined in the national Carotid Occlusion Surgery Study (www.cosstrial.org). Recently published results from the COSS trial demonstrate that superficial temporal artery to middle cerebral artery anastomosis does not provide an overall benefit for ipsilateral 2-yr stroke recurrence when compared to medical therapy alone.

PREVENTION

Prevention of carotid stenosis should include pursuit of a healthy lifestyle and management of risk factors for atherosclerosis.

PATIENT & FAMILY EDUCATION

Patients should be counseled to pursue a healthy lifestyle including exercise and smoking cessation. In addition, patients should take an active role in controlling blood pressure and blood glucose. Further educational materials can be found online at: www.strokecenter.org/education.

BASIC INFORMATION

DEFINITION

Light-headedness, dizziness, presyncope, or syncope in a patient with carotid sinus hypersensitivity is defined as carotid sinus syndrome (CSS). Carotid sinus hypersensitivity is the exaggerated response to carotid stimulation resulting in bradycardia, hypotension, or both. CSS is often considered a variant of neurocardiogenic syncope. The 2013 European Guidelines (ESC) defines CSS as syncope with reproduction of symptoms during carotid sinus massage of 10-second duration. There are two components of CSS: cardioinhibitory and vasodepressor.

SYNONYMS

Carotid sinus syncope
CSS
Carotid sinus hypersensitivity

ICD-10CM CODES

G90.01	Carotid sinus syncope
R55	Syncope and collapse

EPIDEMIOLOGY & DEMOGRAPHICS

- Carotid sinus hypersensitivity accounts for 1% of syncopal episodes (Fig. 1).
- Carotid sinus hypersensitivity is frequently associated with atherosclerosis and diabetes mellitus.
- Incidence increases with age, with an average age of onset at 61 to 74 yr. Fig. 2 illustrates age distribution of the patients with carotid sinus syndrome.
- Men are affected more often than women (2:1).
- CSS is rarely found in patients younger than 50 yr.

MECHANISM

- The carotid sinus is located in the internal carotid artery.
- There is a reflex loop between the mechanoreceptors of the carotid sinus and the vagal nucleus in the midbrain.
- There is an exaggerated cardioinhibitory and vasodepressor reaction caused by decreased sympathetic and increased parasympathetic outflow to the heart and vasculature, respectively.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Often associated with sudden neck movements, especially rotation, neck palpation, shaving, or tight-fitting collars, but can occur in the absence of clear provocation.
- Mild form has symptoms such as fatigue, lightheadedness, nausea, warmth, pallor, or diaphoresis.
- More severe form of the condition has sudden abrupt loss of consciousness without prodrome.

Properly performed carotid sinus massage (CSM) at the bedside is diagnostic. The European Society of Cardiology recommends carotid sinus massage as part of the exam in patients with syncope of unknown etiology and age over 40. This maneuver can elicit three types of responses in patients with carotid sinus hypersensitivity (see "Diagnosis").

- CSM should be performed with the patient in the supine and upright positions while monitoring the patient's blood pressure by cuff and heart rate by ECG.
- CSM should be performed on both the right and left sides but on only one carotid artery at a time.
- Vigorous pressure is applied over the carotid artery, directed posterior to compress the artery against the spinous process of the vertebrae, at the level of the cricoid cartilage for 10 to 30 seconds. Repeat on the opposite side if no effect is produced.
- Contraindications to CSM include the presence of carotid artery bruits, documented carotid artery stenosis >70%, history of stroke or transient ischemic attack <3 mo, history of myocardial infarction <6 mo, history of serious ventricular arrhythmia, or prior carotid endarterectomy.
- Complications of CSM are rare (0.1% to 1%) and may include transient visual disturbance, transient paresis, tachyarrhythmias, or bradyarrhythmias.
- False-positive results with carotid sinus massage may be relatively common in the elderly population. Thus alternative explanations for syncope should be investigated prior to attribution of symptoms to carotid sinus hypersensitivity.

ETIOLOGY

- Idiopathic
- Head and neck tumors (e.g., thyroid)
- Significant lymphadenopathy
- Carotid body tumors
- Prior neck surgery

DIAGNOSIS

- The diagnosis of CSS is made in a patient with a history of syncope when carotid sinus hypersensitivity is demonstrated by CSM and no other cause of syncope is identified.
- CSM can elicit three types of responses diagnostic of carotid sinus hypersensitivity:
  1. Cardioinhibitory type: CSM producing (1) asystole for at least 3 sec in the absence of symptoms or (2) reproduction of symptoms occurring with a decline in heart rate of 30% to 40% or asystole of up to 2 sec in duration. Symptoms should not recur when CSM is repeated after atropine infusion.
  2. Vasodepressor type: CSM producing (1) a decrease in systolic blood pressure of 50 mm Hg in the absence of symptoms or 30 mm Hg in the presence of neurologic symptoms; (2) no evidence of asystole; or (3) neurologic symptoms that persist after infusion of atropine.
  3. Mixed type: CSM producing both types of responses.

DIFFERENTIAL DIAGNOSIS

All causes of syncope

WORKUP

- Evaluation for structural heart disease and other arrhythmias.
- Exclude other causes of syncope or presyncope: Detailed history, physical examination including orthostatic vital signs, ECG.
- Evaluation for vasovagal syncope which may include tilt table testing.

TREATMENT

NONPHARMACOLOGIC THERAPY

Reassurance and education are important. Avoid applying neck pressure from tight collars, shaving, or rapid head turning.

ACUTE GENERAL Rx

Treatment will vary according to the type of carotid hypersensitivity response and symptoms present (see "Chronic Rx").

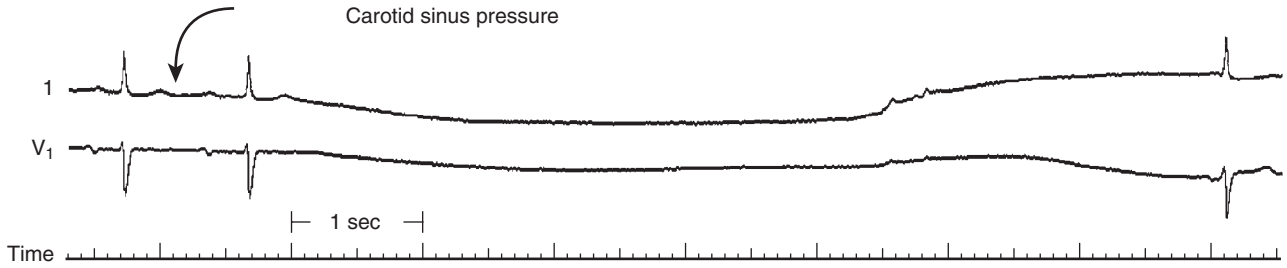

FIG. 1 Carotid sinus hypersensitivity. Two surface electrocardiogram leads are shown during carotid sinus pressure, as indicated. The PR interval is prolonged and followed by a 7.5-second sinus pause ended by a P wave and probable junctional escape complex. The patient was nearly syncopal during this period. (From Issa ZF et al: *Clinical arrhythmology and electrophysiology: a companion to Braunwald's heart disease*, ed 2, Philadelphia, 2012, Saunders.)

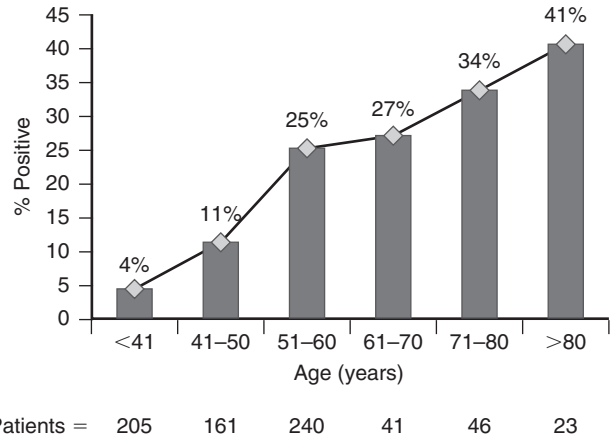

FIG. 2 Age distribution of patients with carotid sinus syndrome. (From Puggioni E et al: Results and complications of the carotid sinus massage performed according to the "method of symptoms," *Am J Cardiol* 89:599-601, 2002.)

CHRONIC Rx

Therapy is divided into three classes: medical, surgical (carotid denervation), and cardiac pacing.

- Surgical therapy has been largely abandoned except in cases of compressing tumors or masses responsible for CSS.
- For infrequent and mildly symptomatic carotid sinus hypersensitivity of either the cardioinhibitory or vasodepressor type, treatment is generally not necessary.
- Cardiac pacing is indicated in patients with recurrent syncope in whom CSM induces ventricular asystole of more than 6 seconds and accompanied by syncope. Dual chamber pacing is recommended as there is evidence that single-chamber pacing worsens syncope recurrence.

Permanent pacing is not indicated for carotid sinus hypersensitivity with no, or only vague, symptoms.

For symptomatic patients with a vasodepressor response to CSM:

- No medical treatment is proven to be effective
- Drugs, such as vasodilators, that would worsen the response should be discontinued or reduced if feasible
- Permissive hypertension
- Increased fluids (≥2 L) and salt intake (>6 g/day)
- Sympathomimetics: Midodrine, titrate from 2.5 to 10 mg tid based on BP and therapeutic response (major side effect in urinary retention in elderly males)
- Serotonin-specific reuptake inhibitors
- Fludrocortisone
- Elastic knee-high or thigh-high stockings
- Carotid sinus denervation

For symptomatic patients with CSS with a mixed response to CSM:

- Combination of dual-chamber permanent pacemaker and agents used to treat vasodepressor response

DISPOSITION

- Up to 50% of the patients have recurrent symptoms.
- No increased mortality rate in patients with idiopathic CSS compared with the general population.

REFERRAL

Cardiology referral is indicated if pacemaker placement is being considered.

PEARLS & CONSIDERATIONS

- The most common type of CSS is cardioinhibitory, followed by mixed and vasodepressor responses.
- Driving restrictions in the 2009 ESC syncope update and 2006 AHA/ACCF consensus document on syncope are stratified according to whether patients have mild or severe syncope.
- Mild carotid sinus syndrome is defined as infrequent mild symptoms (without syncope), with clear precipitating causes (usually standing), warning signs, and infrequent occurrence. For patients with mild sinus hypersensitivity, no driving restrictions are recommended for private or commercial driving.
- Severe carotid sinus syndrome is marked by syncope without warning occurring in any position, without precipitating causes and frequent occurrences. For patients with severe hypersensitivity, all driving is prohibited. If symptoms are controlled, driving is permitted 1 to 6 months after, based on the modality of treatment.

COMMENTS

Prognosis depends on the underlying cause.

AUTHOR: **John Wylie, MD**

BASIC INFORMATION

DEFINITION

Carpal tunnel syndrome (CTS) is a compression neuropathy of the median nerve as it passes under the transverse carpal ligament at the wrist (Figs. E1 and E2). It is the most common entrapment neuropathy.

SYNONYM

CTS

ICD-10CM CODES

G56.0	Carpal tunnel syndrome, unspecified upper limb
G56.01	Carpal tunnel syndrome, right upper limb
G56.02	Carpal tunnel syndrome, left upper limb

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 3.8% of the general population (the most common entrapment neuropathy)
PREVALENT AGE: 30 to 60 yr
PREVALENT SEX: Females are affected two to five times as often as males.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pain, paresthesia in 1st, 2nd, 3rd, and lateral half of 4th fingers, worse at night, with awakenings from sleep due to pain and paresthesias being common.
- ***Tinel sign*** at wrist (Fig. 3): Tapping lightly over the median nerve on the volar surface of the wrist produces a tingling sensation radiating from the wrist to the hand.
- ***Phalen sign*** (Fig. 4): Reproduction of symptoms after 1 min of gentle, unforced wrist flexion.

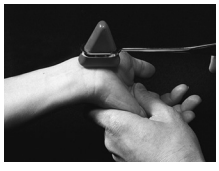

FIG. 3 Tinel sign. The wrist is held in extension while gentle percussion is performed over and just proximal to the transverse carpal ligament. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

FIG. 4 Phalen (wrist flexion) test. With the wrists held in unforced flexion for 30 to 60 seconds, a positive test reproduces or worsens the patient's symptoms. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

- Carpal compression (Durkan) test: Direct pressure over the patient's carpal tunnel for 30 sec elicits symptoms.
- Thenar atrophy in long-standing cases with weakness of thumb abduction and opposition.
- Findings may be bilateral in up to 65% of patients.

ETIOLOGY

- Idiopathic in most cases—caused by increased pressure within the carpal tunnel leading to nerve ischemia
- Commonly associated with diabetes, obesity, female gender, advancing age, pregnancy, hypothyroidism, rheumatologic disorders, autoimmune disorders
- Specific occupations with repetitive strain or job-related mechanical overuse
- May also occur due to mass occupying lesions (tenosynovitis, gout, ganglion) or as a result of trauma (distal radius fractures, perilunate and lunate dislocations, etc.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cervical radiculopathy
- Chronic tendinitis
- Pronator teres syndrome
- Anterior interosseous syndrome
- Complex regional pain syndrome
- Brachial plexopathy, thoracic outlet syndrome
- Polyneuropathy
- Other entrapment neuropathies
- Traumatic wrist injuries
- Vascular disorders (Raynaud syndrome)
- Cervical myelopathy

IMAGING STUDIES

Carpal tunnel syndrome is a clinical diagnosis, but imaging may assist workup in uncertain situations. Accumulating evidence suggests that diagnostic ultrasound may be almost as sensitive as nerve conduction velocity tests and may help identify the structural cause of nerve compression. X-ray or MRI may be helpful in ruling out other conditions.

ELECTRODIAGNOSTIC STUDIES

Nerve conduction velocity tests (NCS) demonstrate impaired sensory conduction across the carpal tunnel and may help guide treatment based on the severity of median nerve compression. Electromyography may show active denervation muscle potentials. Specificity of NCS and electromyography for CTS is >95%, and sensitivity is >85%.

TREATMENT

ACUTE GENERAL Rx

- Activity modification and ergonomic optimization (desk, keyboard).
- Nocturnal wrist splint has been shown to be effective.
- No evidence for effectiveness of NSAIDs.
- Corticosteroid injection of carpal canal on ulnar side of palmaris longus tendon proximal to wrist crease (Figs. E5 and E6): Can be done with palpation guidance or under ultrasound guidance. In different clinical studies, injections have increased patient satisfaction and improved clinical symptoms, albeit temporarily.
- Low-dose oral corticosteroids are optional but usually not effective.
- Short-term benefit from ultrasound therapy (physical therapy modality).
- Carpal tunnel release if no response from nonoperative treatment.

DISPOSITION

Clinical course may have remissions and exacerbations. Some may progress from intermittent to persistent sensory complaints (numbness, tingling, paresthesia) and then to motor symptoms. In pregnancy, symptoms usually resolve spontaneously weeks after delivery.

REFERRAL

Surgical referral is needed if conservative treatment fails. Surgery (sectioning of transverse carpal ligament) is performed by open, endoscopic, or minimal incision techniques, with good long-term results. Carpal tunnel release is one of the most common surgeries performed, with approximately 400,000 conducted per yr. Recurrence and complication rates range from 3% to 19% in some series, with revision required in up to 12% of patients.

PEARLS & CONSIDERATIONS

- The sensory changes of carpal tunnel syndrome spare the thenar eminence. This distinctive pattern occurs because the palmar sensory cutaneous branch of the median nerve arises proximal to the wrist, passing superficial to the tunnel.
- Role of repetitive hand or wrist use and workplace factors in the development of carpal tunnel syndrome remains controversial.
- Recent trials from the Mayo Clinic using ultrasound-guided perineural injection therapy (PIT) using 5% dextrose (D_5W) have shown promising results in patients with mild-to-moderate CTS.[1]

BASIC INFORMATION

DEFINITION

Cataracts are the clouding and opacification of the normally clear crystalline lens of the eye. The opacity may occur in the cortex, the nucleus of the lens, or the posterior subcapsular region, but it is usually in a combination of areas.

SYNONYMS

Congenital cataracts (e.g., from rubella)
Metabolic cataracts (e.g., caused by diabetes)
Hereditary cataracts
Age-related senile cataracts (nuclear sclerotic and cortical cataracts)
Traumatic cataracts
Toxic or drug-induced cataracts (e.g., caused by steroids)
Lenticular opacities

ICD-10CM CODES

H26.9	Cataract, unspecified
H25.0	Senile incipient cataract
H25.1	Senile nuclear cataract
H26.0	Infantile, juvenile and presenile cataract
E11.36	Type 2 diabetes mellitus with diabetic cataract
E13.36	Other specified diabetes mellitus with diabetic cataract
H25.011	Cortical age-related cataract, right eye
H25.012	Cortical age-related cataract, left eye
H25.013	Cortical age-related cataract, bilateral
H25.019	Cortical age-related cataract, unspecified eye
H25.039	Anterior subcapsular polar age-related cataract, unspecified eye
H25.049	Posterior subcapsular polar age-related cataract, unspecified eye
H25.099	Other age-related incipient cataract, unspecified eye
H25.10	Age-related nuclear cataract, unspecified eye
H25.9	Unspecified age-related cataract
H26.019	Infantile and juvenile cortical, lamellar, or zonular cataract, unspecified eye
H26.039	Infantile and juvenile nuclear cataract, unspecified eye
H26.041	Anterior subcapsular polar infantile and juvenile cataract, right eye
H26.042	Anterior subcapsular polar infantile and juvenile cataract, left eye
H26.043	Anterior subcapsular polar infantile and juvenile cataract, bilateral
H26.069	Combined forms of infantile and juvenile cataract, unspecified eye
H26.09	Other infantile and juvenile cataract
H26.101	Unspecified traumatic cataract, right eye
H26.102	Unspecified traumatic cataract, left eye
H26.103	Unspecified traumatic cataract, bilateral
H26.109	Unspecified traumatic cataract, unspecified eye
H26.8	Other specified cataract
H26.9	Unspecified cataract

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Most common cause of treatable blindness; cataract removal is one of the most frequent surgical procedure in patients >65 yr (3.5 million cataract operations per yr). By 2020 more than 30 million Americans will have cataracts. Of Americans >40 yr, 20.5 million (17.2%) have cataracts. Of these, 5% have had surgery.

PEAK INCIDENCE:

- In early life: Congenital and hereditary causes predominant; consider drug related, diabetes, and trauma
- In older age group: Nuclear sclerotic, cortical, and posterior subcapsular cataracts (after 40 yr)

PREDOMINANT AGE: Elderly; some stage of cataract development is present in >50% of persons 65 to 74 yr and in 65% of those >75 yr. Lens opacification and sclerosis begins around age 40 yr and then usually progresses either slowly or rapidly depending on individual and health.

GENETICS: Hereditary with syndromes such as galactosemia, homocystinuria, diabetes

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cloudiness and opacification of the crystalline lens of the eye (Fig. E1, Fig. E2)
- Decrease or absence of the red reflex (important in pediatric ages, since visual acuity is more difficult to assess)
- Painless decreased visual acuity (difficulty reading, seeing road signs: usually gradual, over mo to yr)
- Glare and decreased night vision (early symptom: difficulty with night driving)

ETIOLOGY

- Heredity
- Trauma (may develop cataract quickly with significant trauma)
- Age related
- Drug related (e.g., corticosteroids, smoking)
- Radiation (UV B and ionizing)
- Congenital (genetic, metabolic, or infections)
- Inflammatory (e.g., history of uveitis or previous ocular surgery)
- Diabetes
- Collagen vascular disease

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Corneal lesions
- Retinal lesions, detached retina, tumors
- Vitreous disease, chronic inflammation

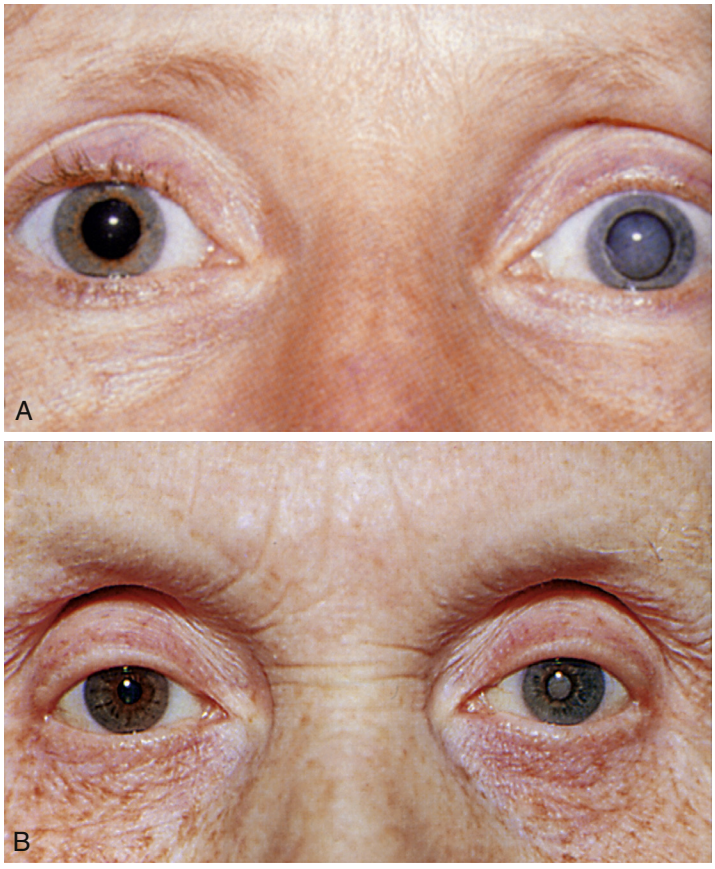

FIG. E1 A and B, Cataract of the left eye. (From Swartz, MH: *Textbook of physical diagnosis, history and examination*, ed 7, Philadelphia, 2014, Elsevier.)

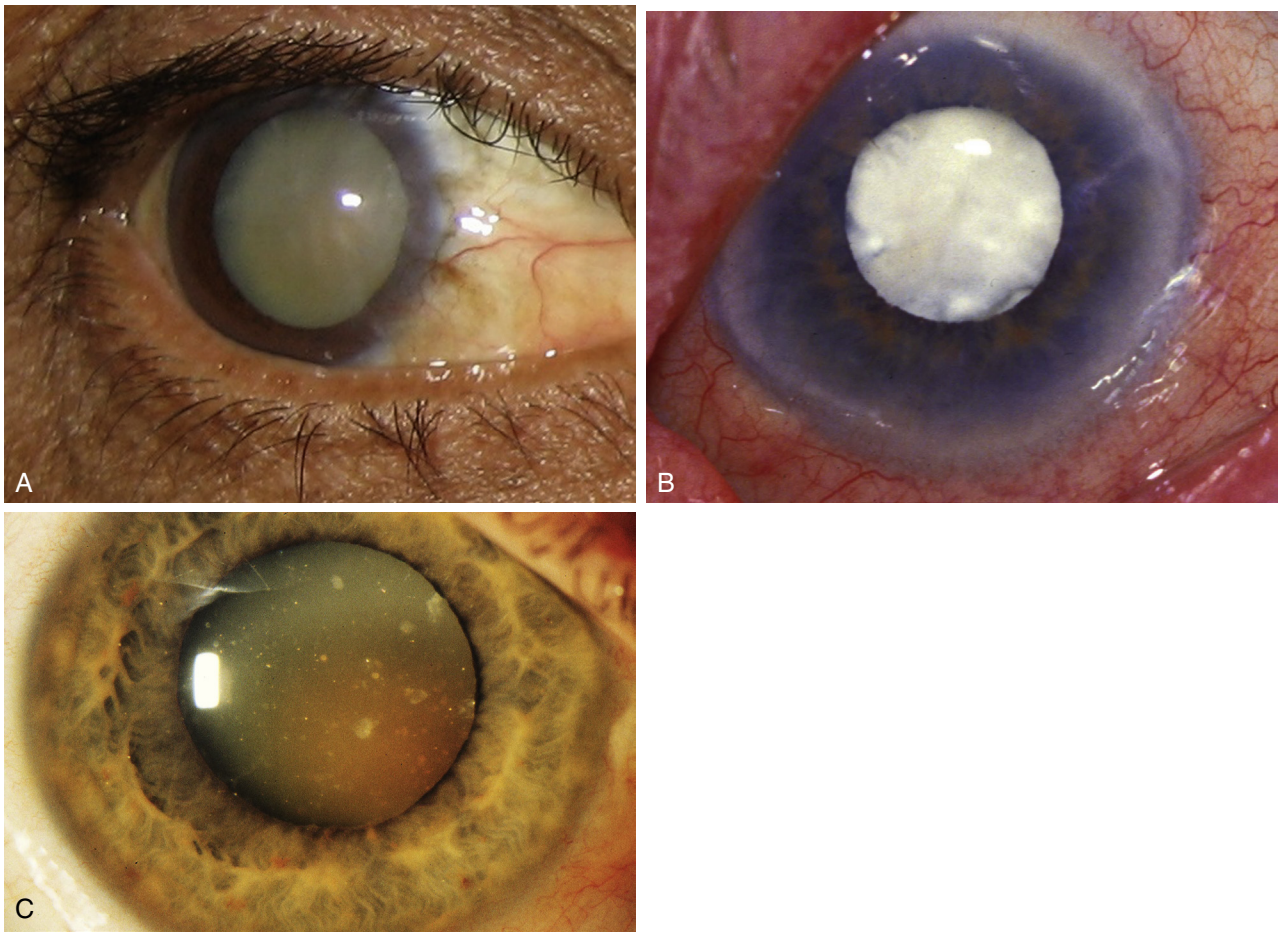

FIG. E2 Cataract maturity. A, Mature cataract—secondary divergent squint is present; **B,** Hypermature cataract with wrinkling of the anterior capsule; **C,** Morgagnian cataract with liquefaction of the cortex and inferior sinking of the nucleus. (Courtesy S Chen, Part A; C Barry, Parts B and C; In Bowling B: *Kanski's clinical ophthalmology, a systemic approach*, ed 8, Philadelphia, 2016, Elsevier.)

WORKUP

- Complete eye examination, including visual acuity and measurement of refractive error, slit lamp examination, dilated funduscopic examination, and brightness acuity testing
- Complete physical examination for other underlying causes

LABORATORY TESTS

- Rarely, urinary amino acid screening and central nervous system imaging studies with congenital cataracts
- Fasting glucose in young adults with cataracts, particularly posterior subcapsular type (PSC)
- Diabetes, collagen vascular disease, other metabolic diseases in younger patients
- Genetic and hereditary evaluation

Rx TREATMENT

There is no evidence that antioxidants or drugs will slow or treat cataracts.

NONPHARMACOLOGIC THERAPY

- Wait until vision is compromised before doing surgery.
- Plan cataract removal with intraocular lens (Fig. E3) implantation when vision is compromised and limiting activities of daily living, such as driving at night or reading. Removal of the cataract should be expected to improve the ability of the patient to perform these activities. Another indication to remove cataracts might be to improve the examination view for treatment and assessment of retinal diseases.
- Decision for timing of surgery depends upon patient complaints, best corrected visual acuity (e.g., 20/50), and glare measurements (brightness acuity test decreases vision significantly).

ACUTE GENERAL Rx

None necessary except when acute glaucoma or inflammation occurs with the rare hypermature cataracts

CHRONIC Rx

- Change glasses as cataracts develop.
- Myopia (near-sighted shift in prescription) is common, and glasses can be adjusted until surgery is contemplated.

DISPOSITION

Refer if sight is compromised or the eye is red or inflamed.

REFERRAL

Refer to ophthalmologist for evaluation for extraction (Fig. E4, Fig. E5) when vision is compromised (see "Nonpharmacologic Therapy").

PEARLS & CONSIDERATIONS

- Patients want to know five things about cataracts:
  1. Chance for vision improvement (other eye conditions often coexist, such as macular degeneration, diabetic retinopathy, corneal diseases, etc., any of

which may limit the expected visual outcome of cataract removal)
2. When vision will improve
3. Risk from surgery (such as infection, hemorrhage, retinal detachment, corneal problems)
4. Effect of surgery, including reduction of refractive errors
5. Types of complications

- Men planning cataract surgery should, if feasible, delay the use of alpha-blockers until after surgery has been completed. The risk of intraoperative floppy iris syndrome is substantial among men taking tamsulosin and similar alpha-blockers. This is often unavoidable, and discontinuation of alpha-blockers does not help, although intraoperative techniques have improved to make floppy iris syndrome less complicated.

BASIC INFORMATION

DEFINITION

Catatonia is a psychomotor syndrome of disordered volition characterized by catalepsy, waxy flexibility, stupor or psychomotor agitation, mutism and negativism (oppositionalism), motor signs such as posturing, mannerisms, grimaces, stereotypies, and echophenomena. Screening and severity rating scales, such as the Bush-Francis Catatonia Rating Scale (BFCRS), are often used to define the condition, as are *Diagnostic and Statistical Manual of Mental Disorders,* Fifth Edition (DSM-5) criteria. Catatonia is an independent syndrome that co-occurs with several mental and medical conditions.

SYNONYMS

Catatonic stupor
Catatonic excitement
Schizophrenic catalepsy
Schizophrenic catatonia
Schizophrenic flexibilitas cerea

ICD-10CM CODES	
F06.1	Catatonic disorder due to known physiological condition; catatonia associated with another mental disorder
F20.2	Catatonic schizophrenia
R40.1	Catatonia, not otherwise specified; catatonic stupor
DSM-5 CODE	
293.89	Catatonia due to a general medical condition

In DSM-5, the specifier "with catatonia" is used for schizophrenia, schizoaffective, schizophreniform, and brief psychotic and substance-induced psychotic disorders. The specifier "with catatonia" is also used for current or most recent major depressive or manic episode in major depressive disorder and in bipolar I and II disorders. Catatonia NOS can also be diagnosed in DSM-5.

In DSM-5, 3 out of the following 12 symptoms must be present to diagnose catatonia:

- Stupor: No or very little psychomotor response
- Catalepsy: Passive rigidity of posture held against gravity
- Mutism: No or very little verbal response
- Waxy flexibility: Persistence of body part positioning after slight resistance
- Negativism: Oppositional nonresponse to instructions
- Posturing: Active spontaneous holding of a position against gravity
- Mannerisms: Caricatured odd movements
- Stereotypy: Frequent repetitive non–goal-directed movements
- Agitation: Nonprovoked heightened psychomotor activity
- Grimacing: Distortions of facial affect
- Echolalia: Repetition of others' words
- Echopraxia: Repetition of others' movements

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence of catatonia has been studied primarily in acutely ill psychiatric inpatients and is present in approximately 10% of patients, with estimates ranging from 5% to 20%, based on prospective studies of psychiatric unit admissions over a span of 1 yr.

PREVALENCE: Catatonia has a 9% to 17% prevalence rate in patients with acute psychiatric disorders, with stuporous catatonia the most common subtype. Catatonic excitement occurs in 15% to 25% of acutely ill hospitalized manic patients. Signs of catatonia occur in up to 17% of adults with autism-spectrum disorders and 30% of patients with delirium. The catatonia prevalence rate was 23.9% in patients undergoing electroconvulsive therapy (ECT) or having elevated creatinine phosphokinase.

GENETICS: Familial clustering of catatonia suggests a genetic component that lacks classic Mendelian inheritance. Studies of periodic catatonia show familial aggregation and evidence for genetic linkage to chromosome 15. Individuals with chromosome 22q11.2 deletion syndrome (DS), which includes conditions such as DiGeorge syndrome and velocardiofacial syndrome, are at risk for catatonia. The 22q11.2DS is associated with disrupted dopamine (DA), γ-aminobutyric acid (GABA), and glutamate systems, which are thought to be dysfunctional in catatonia. Myelin basic protein *Mbp*$^{+/-}$ mice developed late-onset catatonia, and mice lacking 2′ 3′-cyclic nucleotide 3′-phosphodiesterase (*Cnp)* produced defective myelin that leads to degeneration, neuroinflammation, and subsequent catatonia. In the human *Cnp* model, homozygotes for the SNP rs2070106 A allele showed decreased mRNA expression of *Cnp* and a predisposition to catatonia, suggesting that oligodendrocytic dysfunction related to microglial activation may produce a vulnerability to catatonia as in individuals with schizophrenia with *Cnp* rs2070106-AA.

RISK FACTORS: See Table 1 for a list of risk factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Catatonia is a neuropsychiatric syndrome whose cluster of psychomotor signs and symptoms results in aberrations of movement and behavior. Following Kraepelin, catatonia was generally synonymous with schizophrenia until the 1990s. Under DSM-5, catatonia is recognized as due to a medical or psychiatric condition, or unspecified, as, for example, in recurrent idiopathic catatonia. Mood disorders such as major depressive disorder and bipolar disorder are now recognized as more commonly associated with catatonia.

Subtypes of catatonia include **catatonic withdrawal** or **stuporous catatonia,** marked by motoric immobility, staring, mutism, rigidity, withdrawal and refusal to eat, along with more bizarre features, such as posturing, grimacing, negativism, waxy flexibility, echophenomena, stereotypy, verbigeration, and automatic obedience; **excited catatonia,** characterized by purposeless and excessive motor activity, which may include disorganized pressured speech, flight of ideas, verbigeration, disorientation/confusion, and confabulation; and **malignant catatonia,** where catatonic signs are accompanied by fever and dysautonomia. Some experts delineate the catatonia symptom profile into decreased (stupor), increased (excitement), or abnormal psychomotor patterns. Malignant catatonia is associated with increased morbidity and mortality. A specific example of malignant catatonia is neuroleptic malignant syndrome (NMS), induced by dopamine-blocking agents or withdrawal of a dopamine or GABA-A agonist. Another variant, known as manic delirium or delirious mania, exists with features of both excited and malignant catatonia. Periodic catatonia can present with alternating stuporous and excited forms.

ETIOLOGY

Although catatonia is a heterogeneous condition with multiple etiologies and pathophysiologies, myelin changes may indicate a final common pathway, setting in motion an innate neuroinflammatory cascade involving microgliosis in cingulo-frontoparietal regions that then may affect motor functioning in basal ganglia.

See Table 2 for a listing of etiologies.

DIAGNOSIS

Catatonia can lead to medical complications resulting in significant morbidity and mortality, making rapid diagnosis and treatment a priority. Medical complications abound, and the mortality rate for malignant catatonia despite better recog-

TABLE 1 Risk Factors for Catatonia

- Prior episodes of catatonia
- History of or current extrapyramidal symptoms
- Mood disorder with psychomotor retardation or excitement
- Autism-spectrum disorder
- Epilepsy, migraine, and epileptiform activity on EEG
- Frontal, basal ganglia, brain stem, pontine, or cerebellar disease
- Dehydration
- Recent weight loss
- Medications that lower seizure threshold
- Use of dopamine-blocking agents
- Serotonergic medications
- Cocaine use
- Withdrawal from alcohol, benzodiazepines, or other GABA-ergic agents
- Long-term anticholinergic use with recent withdrawal or decrease in dose
- Hyponatremia, hypomagnesemia
- Low serum iron
- Perinatal infectious disease
- MRI findings of cingulo-frontal-parietal cortico-striato-thalamo-cortical circuit lesions

EEG, Electroencephalogram*; GABA*, γ-aminobutyric acid.

TABLE 2 Etiologies

Primary Psychiatric

- Mood disorders
- Schizophrenia
- Autism
- Acute psychoses
- Conversion disorder
- Dissociative disorder
- Obsessive-compulsive disorder
- Personality disorders

Secondary Neuromedical

- Cerebrovascular
- Other CNS disorders
- Neoplasms
- Poisonings
- Infections
- Paraneoplastic and autoimmune encephalitides (especially anti-NMDA receptor antibody encephalitis)
- Metabolic and other medical causes
- Drug related: Induced with dopamine-blocking agents, tacrolimus, disulfiram, and phencyclidine, among many others; Discontinuation of dopamine agonist medications and other antiparkinsonians and of GABA-A agonists and of clozapine can precipitate a catatonia
- Idiopathic

CNS, Central nervous system; *GABA,* gamma aminobutyric acid; *NMDA, N*-methyl-D-aspartate.

nition and treatment is still 9% to 10%. For a list of potential medical complications, see Table 3.

DIFFERENTIAL DIAGNOSIS

- **Locked-in syndrome,** linked to pontine lesions, can be distinguished because patients will generally attempt to communicate with their eyes. Patients in a **persistent vegetative state** may also appear to be catatonic.
- **Stiff person syndrome** is an autoimmune disorder that presents during severe stress with intense lower-extremity spasmodic stiffness that may appear like catatonic posturing, but these patients speak and describe their pain.
- **Extrapyramidal parkinsonism** or **tardive dystonia:** These may have a distinctive tremor but are not negativistic and lack bizarre catatonic psychomotor symptoms.
- **Nonconvulsive status epilepticus** can also produce a catatonic-like state where electroencephalography is essential for accurate diagnosis and prompt management that may minimize cognitive damage.
- **Akinetic mutism,** an extreme form of the abulic syndrome caused by neurologic injury, can be conceptualized as a version of catatonia.
- **Hypoactive delirium** may overlap or coexist with catatonia. It is extremely important to confirm a delirious patient is not also suffering from a catatonic episode, because neuroleptics can worsen simple catatonia, resulting in malignant catatonia.

WORKUP

See Table 4 for evaluation and Table 5 for workup.

TABLE 3 Medical Complications of Catatonia

Simple Nonmalignant Catatonia

- Aspiration
- Burns
- Cachexia
- Dehydration
- Pneumonia
- Pulmonary emboli
- Deep vein thromboses
- Urinary retention and sequelae

Malignant Catatonias

- Acute renal failure
- Acute respiratory distress syndrome
- Cardiac arrest
- Cheyne-Stokes breathing
- Death
- Dysphagia secondary to muscle spasm
- Diffuse intravascular coagulation
- ECG changes
- Gait abnormalities
- Gastrointestinal bleed
- Hepatocellular damage
- Hypoglycemia
- Intestinal pseudoobstruction
- Laryngospasm
- Myocardial infarction
- Necrotizing enterocolitis
- Respiratory arrest
- Rhabdomyolysis
- Seizures
- Sepsis
- Unresponsiveness to pain

ECG, Electrocardiogram.

LABORATORY TESTS

Fever and hyperautonomia, leukocytosis, low sodium, loss of body weight (>5% in 3 wk, >20% in 6 mo), low serum iron, elevated creatinine phosphokinase, cerebrospinal fluid pleocytosis, low serum ceruloplasmin level, myoglobinuria, EEG findings consistent with catatonia, for example, generalized or focal slowing, epileptiform activity

IMAGING STUDIES

- MRI: Mesoencephalofrontal dissolution related to lesions in the frontal cortex, particularly orbitofrontal cortex and anterior cingulate cortex and its basal ganglia thalamo-cortical circuit, parietal cortex, pons, and medial cerebellum
- SPECT: Frontoparietal hypoperfusion—left > right

Rx TREATMENT

NONPHARMACOLOGIC THERAPY AND MANAGEMENT

- Managements includes early recognition, close observation, and frequent vital signs.
- Supportive care is essential: Hydration; nutrition; mobilization; anticoagulation; and pulmonary embolus, and deep vein thrombosis, and aspiration precautions.

TABLE 4 Catatonia Examination Based on Bush-Francis Catatonia Rating Scale

1. Observe while trying to engage in conversation (mutism).
2. Scratch your head or rub nose in exaggerated manner (echopraxia).
3. Examine for rigidity, attempt to reposture (waxy flexibility), and instruct patient to "keep your arm loose" while moving it with lighter and heavier force (gegenhalten).
4. Ask patient to extend arm; place your finger beneath patient's hand and try to raise it slowly after stating: "Do NOT let me raise your arm" (mitgehen-anglepoise lamp).
5. Extend your hand stating: "Do NOT shake my hand" (ambitendency).
6. Reach into your pocket and state: "Stick your tongue out, I want to stick a pin in it (or I want to write on it with my pen)" (automatic obedience).
7. Check for grasp reflex.
8. Check the chart for reports from previous 24 h. Check for PO intake, vital signs, and any behavior changes or incidents.
9. Observe patient each day for activity, abnormal movements, abnormal speech, echopraxia, rigidity, negativism, waxy flexibility, gegenhalten, mitgehen, ambitendency, automatic obedience, and grasp.

PO, By mouth.

Adapted from Bush G, Fink M, Petrides G, Dowling F, Francis A: Catatonia I: rating scale and standardized examination. *Acta Psychiatr Scand* 93:129-136, 1996.

TABLE 5 Workup for Catatonia

- EEG
- Neuroimaging
- Routine blood work including creatine phosphokinase and serum iron level and other blood work as indicated
- Urine for myoglobinuria
- Ceruloplasmin for Wilson disease as indicated
- Cerebrospinal fluid analysis including antibody titers for autoimmune limbic encephalitides as indicated

EEG, Electroencephalogram.

- Discontinue antipsychotics or other drugs such as metoclopramide, which can cause or worsen catatonia.
- Restart recently withdrawn dopamine agonists, antiparkinsonians, and benzodiazepines, especially in patients with parkinsonism.
- Institute supportive measures (e.g., cooling blankets, parenteral fluids, antihypertensives) if malignant catatonia emerges.

ACUTE GENERAL Rx (SEE TABLE 6)

CHRONIC RX: Maintenance medications or ECT and close psychiatric follow-up for recurrence

DISPOSITION

Disposition will vary depending on response. Because response rate to lorazepam and ECT is high, ranging from 65% to 85%, many patients can return home. Some patients with chronic catatonia who do not respond well need long-term care in facilities.

TABLE 6 A Treatment Approach for Catatonic States

- Lorazepam treatment trial, if there are no contraindications, can give 2 mg IV and observe for effect; if none, come back in 3 h and do it again; if no effect, can do it again in 3 h for a total of 6 mg over 24 h. Can go up to 20 mg/d in divided doses before saying the patient has failed to be lysed, especially if partial improvement has been seen.
- For those who show partial improvement on day 1, can continue 2 mg IV q8h for 3-4 days and may continue it longer if benefit is greater than risk, to maintain the level of improvement achieved, especially if the catatonia has been present >1 mo.
- After lysis of the catatonia, can switch to sublingual or oral in divided doses. This usually maintains the effect, although an occasional patient needs IV dose reinstituted.
- After lysis, psychosis depending on etiology may continue, and sometimes patients will need cautious use of an atypical antipsychotic medication. Most often if circumstances warrant it, one can use a low-potency, atypical antipsychotic such as olanzapine or aripiprazole while continuing lorazepam to buffer against re-emergence of catatonia and NMS.
- It is important to have patients with catatonia diathesis who need a neuroleptic on a benzodiazepine until there is more confidence that the patient is less in danger of catatonia.
- If patient is not improving: Trial of adjunctive amantadine: 100 mg/d titrating up every 3 days to 400 mg/d in divided doses. Trial of adjunctive memantine: 10 mg/d for 3 or 4 days, then increase to 10 mg bid if ineffective. Trial of adjunctive topiramate: 100 mg bid up to 200 mg bid. Trial of dopamine agonists (bromocriptine 2.5 mg bid-tid up to 45 mg/d, Sinemet, lisuride, and pramipexole have all been used with anecdotal success). Zolpidem 5-10 mg PO, if feasible, can be used as a test for catatonia response.
- For malignant catatonia, use lorazepam trial as described earlier. If still catatonic, ECT is often lifesaving and should be instituted prior to day 5 of syndrome. If ECT is not available or refused by surrogate decision-maker, can try a dopamine agonist with or without dantrolene 100-300 mg/d in divided doses starting with 1-2.5 mg/kg IV; when acidosis, rigidity, and fever resolve, then 1 mg/kg IV q6h × 48 h; with further improvement, taper to q12h, then 1 mg/kg each day × 8 days.
- For catatonic excitement (delirious mania): Consider lorazepam and ECT first; then lorazepam and olanzapine, lorazepam and Depakote, or carbamazepine.
- For catatonia secondary to autoimmune encephalitides (e.g., anti-NMDA receptor encephalitis), use of anti-inflammatory strategies is indicated: steroids, intravenous Ig, rituximab, cyclophosphamide, plasmapheresis.

bid, Twice daily; *ECT,* electroconvulsive therapy; *Ig*, immunoglobulin; *IV,* intravenous; *NMDA, N*-methyl-D-aspartate; *NMS,* neuroleptic malignant syndrome; *PO,* by mouth; *tid,* three times daily.

Adapted from Fricchione G, Beach S: Cingulate aspects of catatonia and treatment. In Vogt B (ed): *Cingulate cortex*. New York, 2019, Elsevier.

PEARLS & CONSIDERATIONS

- Simple catatonias treated with neuroleptics often develop NMS.
- Once malignant (catatonia with autonomic instability and hyperthermia), mortality risk increases.
- Patients with malignant catatonia who are receiving neuroleptics have an even higher mortality risk.
- Catatonia that has been present for <1 mo is often easier to treat.
- While attempting pharmacotherapy, it is prudent to introduce the potential need for ECT by seeking surrogate approval and consent.

PREVENTION

Use of dopamine blocking and GABA-A blocking medications in high-risk groups requires caution.

PATIENT & FAMILY EDUCATION

Patient and family education is available at the Penn State University Catatonia Information Center website (http://www.catatonia.org; Andrew Francis, PhD, MD, Director).

BASIC INFORMATION

DEFINITION

Cat-scratch disease (CSD) is an infectious disease consisting of gradually enlarging regional lymphadenopathy occurring after contact with a feline. Atypical presentations are characterized by a variety of neurologic manifestations as well as granulomatous involvement of the eye, liver, spleen, and bone. The disease is usually self-limiting, and recovery is complete; however, patients with atypical presentations, especially if immunocompromised, may suffer significant morbidity and mortality.

SYNONYMS

CSD
Cat-scratch fever
Benign inoculation lymphoreticulosis
Nonbacterial regional lymphadenitis

ICD-10CM CODE
A28.1 Cat-scratch disease

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Unknown
INCIDENCE (IN U.S.)
- 9 to 10 cases per 100,000 persons per yr (22,000 cases per yr)
- Majority of reported cases occur in persons <21 yr

PEAK INCIDENCE: August through January

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic, most common finding: Regional lymphadenopathy occurring within 2 wk of a scratch or contact with felines; usually a new kitten in the household
- Tender, swollen lymph nodes most commonly found in the head and neck (Fig. E1), followed by the axilla and the epitrochlear, inguinal, and femoral areas
- Erythematous overlying skin, showing signs of suppuration from involved lymph nodes
- On careful examination, evidence of cutaneous inoculation in the form of a nonpruritic, slightly tender pustule or papule
- Fever in most patients
- Malaise and headache in fewer than a third of patients
- Atypical presentations in less than 15% of cases
  1. Usually in association with lymphadenopathy and a low-grade or frank fever (>101° F, >38.3° C)
  2. Include granulomatous involvement of the conjunctiva (Parinaud oculoglandular syndrome) and focal masses in the liver, spleen, and mesenteric nodes
- CNS involvement: Neuroretinitis, encephalopathy, encephalitis, transverse myelitis, seizure activity, and coma
- Osteomyelitis in adults and children
- Can be a cause of culture-negative endocarditis
- In HIV-infected and other immunocompromised patients, *Bartonella henselae* is the cause of bacillary angiomatous and peliosis hepatis

ETIOLOGY

- Major cause: *Bartonella henselae*, possibly *Afipia felis* and *Bartonella clarridgeiae*
- Mode of transmission: Predominantly by direct inoculation through the scratch, bite, or lick of a cat, especially a kitten
- Also can be transmitted by flea bite (with the flea obtaining the bacteria from a bacteremic cat); rarely after exposure to a dog, probably secondary to flea bites
- Approximately 2 wk after introduction of the bacteria into the host, regional lymphatic tissues displaying granulomatous infiltration associated with gradual hypertrophy
- Possible dissemination to distant sites (e.g., liver, spleen, and bone), usually characterized by focal masses or discrete parenchymal lesions

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Granulomas of this syndrome must be differentiated from those associated with:
- Tularemia
- Tuberculosis or other mycobacterial infections
- Brucellosis
- Sarcoidosis
- Sporotrichosis or other fungal diseases
- Toxoplasmosis
- Lymphogranuloma venereum
- Benign and malignant tumors such as lymphoma

WORKUP

Diagnosis should be considered in patients who present with a predominant complaint of gradually enlarging regional (focal) lymphadenopathy, often with fever and a recent history of having contact with a cat. A primary ulcer at the site of the cat scratch may or may not be present at the time lymphadenopathy becomes manifest.

LABORATORY TESTS

- Serologies: An IFA *Bartonella* serology (titer ≥1:64) is strongly suggestive of infection. An IFA titer >1:256 is diagnostic.
- A PCR assay on tissue, blood or intraocular fluid is also available but sensitivity is not high.
- Lymph node biopsy: Granulomatous inflammation consistent with CSD.
- Warthin-Starry silver stain on biopsy can identify the bacteria.
- Histopathologically, Warthin-Starry silver stain has been used to identify the bacillus.
- Culture: *B. henselae* is a fastidious, slow-growing, gram-negative rod that requires specific culture techniques for tissue or blood.
- Routine laboratory findings:
  1. Mild leukocytosis or leukopenia
  2. Infrequent eosinophilia
  3. Elevated ESR or CRP
- Abnormalities of bilirubin excretion and elevated hepatic transaminases are usually secondary to hepatic obstruction by granuloma, mass, or lymph node.
- In patients with neurologic manifestations, lumbar puncture usually reveals normal CSF, although there may be a mild pleocytosis and modest elevation in protein.
- CSD skin test is no longer used for clinical purposes.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Warm compresses to the affected nodes
- In cases of encephalitis or coma: Supportive care

ACUTE GENERAL Rx

- This disease is typically self-limited and generally resolves within 2 to 6 months. Most studies show no additional benefit from antibiotic therapy.
- It would be prudent to treat severely ill patients, especially if immunocompromised, with antibiotic therapy, because these patients tend to suffer dissemination of infection and increased morbidity.
- *Bartonella* is usually sensitive to a 5-day course of azithromycin (500 mg on day 1 followed by 250 mg for 4 days for weight >45.5 kg; 10 mg/kg on day 1 followed by 5 mg/kg for 4 days for weight <45.5 kg) or alternatively tetracycline, sulfa, and the quinolones can be used for 7 to 10 days.
- Hepatosplenic disease, neuroretinitis, and endocarditis require longer courses of therapy.
- Antipyretics and NSAIDs may also be used for lymphadenitis.

DISPOSITION

- Overall prognosis is good.
- Surgical drainage is generally not recommended. Excision of the entire lymph node may be necessary if not responding after prolonged treatment.

REFERRAL

- For diagnostic aspiration or excision in presence of regional lymphadenopathy, bone lesions, and mesenteric lymph nodes and organs
- Infectious diseases specialist for organ involvement including endocarditis
- To ophthalmologist for ocular granulomas

Cavernous Sinus Thrombosis PTG

BASIC INFORMATION

DEFINITION

Cavernous sinus thrombosis (CST) is a late complication of either facial or paranasal sinus infection, resulting in thrombosis of the cavernous sinus and inflammation of its surrounding anatomic structures, including cranial nerves III, IV, V (ophthalmic and maxillary branch), and VI, and the internal carotid artery.

SYNONYMS

CST
Intracranial venous sinus thrombosis or thrombophlebitis
Dural sinus thrombosis

ICD-10CM CODE
G08 Intracranial and intraspinal phlebitis and thrombophlebitis

EPIDEMIOLOGY & DEMOGRAPHICS

- CST is rare in the post-antibiotic era.
- Before antibiotics the mortality rate was 80% to 100%.
- With antibiotics and early diagnosis, mortality rates have fallen to ~20%.
- Reported morbidity rates have also declined from between 50% and 70% to about 20% to 30% with advances in imaging modalities and aggressive medical care.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Can be either an acute and fulminant disease or an indolent and subacute presentation.
- Septic cases of CST commonly present with high-grade fever (picket fence pattern) and signs of sepsis.
- Headache, although not specific, is the most common presenting symptom and may precede fever and periorbital edema by several days. Elderly patients, however, may only demonstrate alteration in mental status without antecedent headache. The triad of unilateral or bilateral progressive chemosis, periorbital edema, and proptosis with headache is a classical presentation in patients with CST. These signs and symptoms are related to the anatomic structures affected within the cavernous sinus, notably cranial nerves III to VI, as well as impaired venous drainage from the orbit and eye.

Other common signs and symptoms include:

- Ptosis.
- Cranial nerve palsies (III, IV, V1, V2, VI).
  1. Ophthalmoplegia caused by involvement of cranial nerves III, IV, and VI is present in most cases. Sixth nerve palsy can occur early in some cases of septic CST, especially when originating from the sphenoid sinus owing to its anatomic proximity.
  2. Hypoesthesia or hyperesthesia of the ophthalmic and maxillary branch of the fifth nerve is common. Periorbital sensory loss and impaired corneal reflex may be noted.
- Papilledema, retinal hemorrhages, and decreased visual acuity progressing to blindness may occur from venous congestion within the retina.
- Pupil may be dilated and sluggishly reactive.
- Headache with nuchal rigidity and changes in mental status may occur if the infection spreads intracranially to the meninges and brain parenchyma.
- Infection can spread to the contralateral cavernous sinus through the intercavernous sinuses within 24 to 48 hours of initial presentation.
- Patients may also develop signs and symptoms of pituitary insufficiency.

ETIOLOGY

- CST most commonly results from contiguous spread of an infection from either the sinuses (sphenoid, ethmoid, or frontal) or the medial third of the face (areas around the eyes and nose that drain to the ophthalmic vein). Nasal furuncles are the most common facial infection to produce this complication. Less-common primary sites of infection include dental abscess, tonsils, soft palate, middle ear, or orbit (orbital cellulitis).
- CST also can result from hematogenous spread of infection to the cavernous sinus by the superior and inferior ophthalmic veins or through the lateral and sigmoid sinuses. Depending on the pressure gradients, infection can spread in a retrograde direction because the dural sinuses are valveless.
- *Staphylococcus aureus* is the most commonly identified pathogen, found in 60% to 70% of the cases.
- *Streptococcus* is the second leading cause.
- Gram-negative rods and anaerobes may also lead to CST.
- Rarely, *Aspergillus fumigatus* and mucormycosis cause CST.
- Risk factors for dural sinus thrombosis include venous hypercoagulable disorders, infections (see previous), trauma, malignancies, systemic inflammatory disorders, pregnancy, and dehydration.

DIAGNOSIS

- The diagnosis of CST is made by clinical suspicion and confirmed by appropriate imaging studies.
- Proptosis, ptosis, chemosis, and cranial nerve palsy beginning in one eye and progressing to the other eye establish the diagnosis.

DIFFERENTIAL DIAGNOSIS

- Orbital or periorbital cellulitis
- Internal carotid artery aneurysm or fistula
- Cerebrovascular disease
- Migraine headache
- Allergic blepharitis
- Thyroid ophthalmopathy
- Orbital neoplasm
- Meningitis
- Epidural and subdural infections
- Epidural and subdural hematoma
- Subarachnoid hemorrhage
- Acute angle-closure glaucoma
- Trauma

WORKUP

CST is a clinical diagnosis, with laboratory tests and imaging studies confirming the clinical impression.

LABORATORY TESTS

- Complete blood count, erythrocyte sedimentation rate, blood cultures, and sinus cultures help establish and identify an infectious primary source. Metabolic panel to look for electrolyte imbalances in cases of suspected pituitary involvement (DI/SIADH).
- Lumbar puncture (LP) helps to distinguish CST from more localized processes (e.g., sinusitis, orbital cellulitis). LP reveals inflammatory cells in 75% of cases. In half of these cases, the cerebrospinal fluid profile is typical for a parameningeal focus (high white blood cells with polymorphonuclear and/or mononuclear cells, normal glucose, normal protein, culture negative), and in one third may be similar to that of bacterial meningitis.

IMAGING STUDIES

- MRI with gadolinium, including magnetic resonance angiography and magnetic resonance venogram (Fig. 1), is more sensitive than CT scan and is the imaging study of choice to diagnose CST. Findings may include deformity of the internal carotid artery within the cavernous sinus and an obvious signal hyperintensity within thrombosed vascular sinuses.
- Noncontrast CT scan of the head and orbits may demonstrate increased density in the region of the cavernous sinus but has relatively low sensitivity. Contrast-enhanced CT scan may reveal underlying sinusitis, thickening of the superior ophthalmic vein, and irregular filling defects within the cavernous sinus; however, findings may be normal early in the disease course.

TREATMENT

NONPHARMACOLOGIC THERAPY

Recognizing the primary source of infection (i.e., facial cellulitis, middle ear, and sinus infections) and treating the primary source expeditiously is the best way to prevent CST.

ACUTE GENERAL Rx

- Appropriate therapy should take into account the primary source of infection as well as possible associated complications such as brain abscess, meningitis, or subdural empyema.
- Broad-spectrum intravenous antibiotics are used as empiric therapy until a definite pathogen is found. Treatment should include vancomycin to cover hospital or community-acquired methicillin-resistant *Staphylococcus aureus* or resistant *Streptococcus pneumoniae* plus a third- or fourth-generation cephalosporin:
  1. Vancomycin (1 g q12h with normal renal function) plus either ceftriaxone (2 g q12h) or cefepime (2 g q8 to 12h).

2. Metronidazole 500 mg IV q6h should be added if anaerobic bacterial infection is suspected (dental or sinus infection).

- Most experts recommend anticoagulation with heparin after the diagnosis is confirmed, unless surgical intervention is planned, or there is evidence of an expanding hematoma. Spontaneous intracranial hemorrhage should first be ruled out before initiating heparin therapy. Early heparinization has been suggested in patients with unilateral CST to prevent clot propagation. Coumadin therapy should be avoided in the acute phase of the illness but should ultimately be instituted to achieve an INR of 2 to 3 and continued until the infection, symptoms, and signs of CST have either resolved or significantly improved. Anticoagulation with warfarin is generally continued for a minimum of 3 to 6 mo. Retrospective case reports and case series have demonstrated a favorable outcome in terms of decreased mortality and morbidity in the anticoagulated patients.
- Steroid therapy is also controversial but may prove helpful in reducing cranial nerve dysfunction or when progression to pituitary insufficiency occurs. Corticosteroids should only be instituted after appropriate antibiotic coverage. Dexamethasone 10 mg q6h is the treatment of choice.
- Emergent surgical drainage with sphenoidotomy is indicated if the primary site of infection is believed to be the sphenoid sinus.

CHRONIC Rx

- Patients with CST are usually treated with prolonged courses (3 to 4 wk) of IV antibiotics. If there is evidence of complications such as intracranial suppuration, 6 to 8 wk of total therapy may be warranted.
- All patients should be monitored for signs of complicated infection, continued sepsis, or septic emboli while antibiotic therapy is being administered. Relapse of septic CST can occur after an initial improvement weeks after stopping antibiotic treatment.

DISPOSITION

- CST can be a life-threatening, rapidly progressive infectious disease with high morbidity and mortality rates (30%) despite antibiotic use. Morbidity and mortality rates are increased in cases of sphenoid sinus infection.
- Complications of untreated CST include extension of thrombus to other dural sinuses, carotid thrombosis with concomitant strokes, subdural empyema, brain abscess, or meningitis. Septic embolization may also occur to the lungs, resulting in acute respiratory distress syndrome, pulmonary abscess, empyema, and pneumothorax.
- Thirty percent of treated patients develop long-term sequelae, including cranial nerve palsies, blindness, pituitary insufficiency, and hemiparesis.

REFERRAL

If suspected, CST should be considered a medical emergency. Depending on source of infection, appropriate consultation should be made (i.e., ear-nose-throat, ophthalmology, and infectious disease).

PEARLS & CONSIDERATIONS

COMMENTS

CST is a medical emergency and should be suspected with progressing chemosis, proptosis, and cranial neuropathy in a patient with headaches with or without fever.

The anatomy of the cavernous sinus explains the clinical findings: The cavernous sinus lies just above and lateral to the sphenoid sinus and drains the middle portion of the face by the superior and inferior ophthalmic veins; cranial nerves III, IV, V, and VI pass alongside or through the cavernous sinus.

BASIC INFORMATION

DEFINITION

Celiac disease is a chronic autoimmune disease characterized by malabsorption and diarrhea precipitated by ingestion of food products containing gluten. Gluten is a protein complex found in wheat, rye, and barley.

SYNONYMS

Gluten-sensitive enteropathy
Celiac sprue
Nontropical sprue

ICD-10CM CODE
K90.0 Celiac disease

EPIDEMIOLOGY & DEMOGRAPHICS

- The prevalence of celiac disease is 0.5% to 1% in the general population in North America and Western Europe and 5% in high-risk groups such as first-degree relatives of persons with the disease. The prevalence of celiac disease in the U.S. has increased fourfold over the past three decades, but the trend is flattening. The decline in undiagnosed celiac disease may reflect greater public and professional attention to gluten-related issues. Worldwide celiac disease affects 0.6% to 1% of the population. Celiac disease is significantly more common in persons with type 1 diabetes mellitus (DM) and is associated with greater risk of retinopathy and nephropathy in this population.
- Incidence is highest during infancy and the first 36 mo of life (after introduction of foods containing gluten), in the third decade (frequently associated with pregnancy and severe anemia during pregnancy), and in the seventh decade.
- There is a slight female predominance.
- The average age of diagnosis is in the fifth decade of life.
- The risk for celiac disease is 5% to 10% in newborn children of parents with the disease and nearly 20% in siblings.
- It is estimated that only 10% to 15% of persons with celiac disease in the U.S. have been diagnosed.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination may be entirely within normal limits.
- Weight loss, dyspepsia, short stature, and failure to thrive may be noted in children and infants.
- Weight loss, fatigue, and diarrhea are common in adults.
- Abdominal pain, nausea, and vomiting are unusual.
- Pallor as a result of iron-deficiency anemia is common.
- Atypical forms of the disease are being increasingly recognized and include osteoporosis, short stature, anemia, infertility, and neurologic problems. Manifestations of calcium deficiency, such as tetany and seizures, are rare and can be exacerbated by coexistent magnesium deficiency.
- Angular cheilitis, aphthous ulcers, atopic dermatitis, and dermatitis herpetiformis are frequently associated with celiac disease.
- Table 1 summarizes the clinical spectrum of celiac disease.
- Table 2 summarizes extraintestinal manifestations of celiac disease.
- Disorders associated with celiac disease are summarized in Box 1.

ETIOLOGY

- Celiac sprue is considered an autoimmune-type disease, with tissue transglutaminase (tTG) suggested as a major autoantigen. It results from an inappropriate T-cell–mediated immune response against ingested gluten in genetically predisposed individuals who carry either *HLA-DQ2* or *HLA-DQ8* genes. There is sensitivity to gliadin, a protein fraction of gluten found in wheat, rye, and barley. In patients with celiac disease, immune responses to gliadin fractions promote an inflammatory reaction, mainly in the upper small intestine, manifested by infiltration of the lamina propria and the epithelium with chronic inflammatory cells and villous atrophy. The susceptibility to celiac disease may also be related to other environmental factors such as bacterial microbiome and reovirus infection). Table 3 summarizes biomarkers in the diagnosis of celiac disease and monitoring compliance to gluten-free diet.
- Seroconversion to celiac autoimmunity may occur at any time.
- Timing of introduction of gluten into the infant diet is associated with the appearance of celiac disease in children at risk. Children initially exposed to gluten in the first 3 mo of life have a fivefold increased risk. Current recommendations are to delay introduction of gluten into the diet of a genetically susceptible infant until 4 to 6 mo of age while the mother continues to breastfeed.

DIAGNOSIS

Diagnostic criteria for celiac disease require at least four out of five or three out of four if the *HLA* genotype is not performed:

1. Typical symptoms of celiac disease
2. Positivity of serum celiac disease Immunoglobulin A (IgA) class autoantibodies at high titer
3. *HLA-DQ2* or *HLA-DQ8* genotypes
4. Celiac enteropathy at the small intestinal biopsy
5. Response to gluten-free diet

DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease
- Laxative abuse
- Intestinal parasitic infestations
- Lactose intolerance
- Other: Irritable bowel syndrome, tropical sprue, chronic pancreatitis, Zollinger-Ellison syndrome, cystic fibrosis (children), lymphoma, eosinophilic gastroenteritis, short bowel syndrome, Whipple disease
- Intestinal lymphoma, tuberculosis, radiation enteritis, HIV enteropathy

LABORATORY TESTS

- IgA anti-tTG antibody by enzyme-linked immunosorbent assay (tissue transglutaminase [tTG] test) is the best screening serologic test for celiac disease. IgA antiendomysial antibodies (EMA) test is also a good screening test for celiac disease but is best used as a confirmatory test in cases of borderline positive results. In patients with IgA deficiency, the IgG deamidated gliadin peptide (DPG) test (deamidated gliadin peptides) can be used for diagnosis. Screening of close relatives is initially done with polymerase chain reaction (PCR) testing for *HLA DQ2* or *HLA DQ8.* Those that are positive should then have serum tTG IgA screening. All diagnostic serologic testing for celiac disease should be performed before a gluten-free diet is initiated. Table 4 summarizes the sensitivity, specificity, and positive and negative predictive values of serologic tests for untreated celiac disease.
- CBC, ferritin level: Iron-deficiency anemia (microcytic anemia, low ferritin level) may be present.
- Celiac disease can lead to malabsorption: Screen for vitamin B_{12} level, folate level, vitamin D level, serum calcium, albumin, magnesium; vitamin B_{12} deficiency, vitamin D deficiency, hypomagnesemia, and hypocalcemia are not uncommon in celiac disease.
- Biopsy of the small bowel, considered the gold standard, has been questioned as a reliable and conclusive test in all cases. It may be reasonable in children with significant elevations

TABLE 1 Clinical Spectrum of Celiac Disease

Symptomatic
Frank malabsorption symptoms: Chronic diarrhea, failure to thrive, weight loss
Extraintestinal manifestations: Anemia, fatigue, hypertransaminasemia, neurologic disorders, short stature, dental enamel defects, arthralgia, aphthous stomatitis
Silent
No apparent symptoms in spite of histologic evidence of villous atrophy
In most cases identified by serologic screening in at-risk groups (see Laboratory Tests)
Latent
Subjects who have a normal histology, but at some other time, before or after, have shown a gluten-dependent enteropathy
Potential
Subjects with positive celiac disease serology but without evidence of altered jejunal histology
It might or might not be symptomatic

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

TABLE 2 Extraintestinal Manifestations of Celiac Disease

Manifestation	Probable Cause(s)
Cutaneous	
Ecchymoses and petechiae	Vitamin K deficiency; rarely, thrombocytopenia
Edema	Hypoproteinemia
Dermatitis herpetiformis	Epidermal (type 3) tTG autoimmunity
Follicular hyperkeratosis and dermatitis	Vitamin A malabsorption, vitamin B complex malabsorption
Endocrinologic	
Amenorrhea, infertility, impotence	Malnutrition, hypothalamic-pituitary dysfunction, immune dysfunction
Secondary hyperparathyroidism	Calcium and/or vitamin D malabsorption with hypocalcemia
Hematologic	
Anemia	Iron, folate, vitamin B_{12}, or pyridoxine deficiency
Hemorrhage	Vitamin K deficiency; rarely, thrombocytopenia due to folate deficiency
Thrombocytosis, Howell-Jolly bodies	Hyposplenism
Hepatic	
Elevated liver biochemical test levels Autoimmune hepatitis	Lymphocytic hepatitis Autoimmunity
Muscular	
Atrophy	Malnutrition due to malabsorption
Tetany	Calcium, vitamin D, and/or magnesium malabsorption
Weakness	Generalized muscle atrophy, hypokalemia
Neurologic	
Peripheral neuropathy	Deficiencies of vitamin B_{12} and thiamine; immune-based neurologic dysfunction
Ataxia	Cerebellar and posterior column damage
Demyelinating central nervous system lesions	Immune-based neurologic dysfunction
Seizures	Unknown
Skeletal	
Osteopenia, osteomalacia, and osteoporosis	Malabsorption of calcium and vitamin D, secondary hyperparathyroidism, chronic inflammation
Osteoarthropathy	Unknown
Pathologic fractures	Osteopenia and osteoporosis

tTG, Tissue transglutaminase.

BOX 1 Disorders Associated with Celiac Disease

Definite Association
Bird-fancier lung
Dermatitis herpetiformis
Diabetes mellitus type 1
Down syndrome
Epilepsy with cerebral calcification
Fibrosing alveolitis
Hypothyroidism or hyperthyroidism
IBD
IgA mesangial nephropathy
Idiopathic pulmonary hemosiderosis
IgA deficiency
Microscopic colitis
Recurrent pericarditis
RA
Sarcoidosis

Negative Association
Diabetes mellitus type 2

Possible Association
Addison disease
Autoimmune hemolytic anemia
Autoimmune liver diseases
Cavitary lung disease
Congenital heart disease
Cystic fibrosis
Immune thrombocytopenic purpura
Iridocyclitis or choroiditis
Macroamylasemia
Myasthenia gravis
Polymyositis
Schizophrenia
Sjögren syndrome
Systemic and cutaneous vasculitides
SLE

IBD, Inflammatory bowel disease; *IgA,* immunoglobulin A; *RA,* rheumatoid arthritis; *SLE,* systemic lupus erythematosus.
Modified from Mulder CJ, Tytgat GN: Coeliac disease and related disorders, *Neth J Med* 31:286-299, 1987. In Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

of tTG levels (>100 U) to first try a gluten-free diet and consider biopsy in those who do not improve with diet. Repeat small-bowel biopsies are no longer required to show healing when there is a clear response to a gluten-free diet.
- The HLA-DQ2 allele is identified in >90% of patients with celiac disease, and HLA-DQ8 is identified in most of the remaining patients. These genes occur in only 30% to 40% of the general population. Their greatest diagnostic value is in their negative predictive value, making them useful when negative in ruling out the disease.

IMAGING STUDIES

- Consider bone density in newly diagnosed adult patients.
- Capsule endoscopy can be used to evaluate mucosa of the small intestine, especially if future innovations will allow mucosal biopsy.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Patients should be instructed on a gluten-free diet (avoidance of wheat, rye, and barley). Safe grains (gluten-free) include rice, corn, oats, buckwheat, millet, amaranth, quinoa, sorghum, and teff (an Ethiopian cereal grain). The lowest amount of daily gluten that causes damage to the celiac intestinal mucosa is 10 to 15 mg/day. One slice of bread contains 1.6 g of gluten. Principles of initial dietary therapy for patients with celiac disease are summarized in Box 2.

GENERAL Rx

- Correct nutritional deficiencies with iron, folic acid, calcium, vitamin D, and vitamin B_{12} as needed.
- Prednisone 20 to 60 mg qd gradually tapered is useful in refractory cases.
- Lifelong gluten-free diet is necessary. A referral to a nutritionist experienced in celiac disease and gluten-free diet is recommended at initial diagnosis.

DISPOSITION

- Prognosis is good with adherence to a gluten-free diet. Rapid improvement is usually seen within a few days of treatment. Healing of the intestinal damage typically occurs within 6 to 24 mo after initiation of the diet. Lack of response to gluten-free diet occurs in 5% of patients and is due to unintentional ingestion of gluten or presence of coexisting GI disorders such as inflammatory bowel disease (IBD), lactose or other carbohydrate intolerance, and pancreatic insufficiency.
- Serial antigliadin or antiendomysial antibody tests can be used to monitor the patient's adherence to a gluten-free diet.
- Repeat small-bowel biopsy after treatment generally reveals significant improvement. It is also useful to evaluate for increased risk of small-bowel T-cell lymphoma in these patients, especially untreated patients. Some experts recommend a repeat biopsy only in selected patients who have an unsatisfactory response to a strict gluten-free diet; however, recent data (Lebwohl et al) show that the risk for lymphoproliferative malignancy (LPM) is affected by the results of follow-up intestinal biopsy performed to document mucosal healing. Increased risk for LPM in CD is associated with the follow-up biopsy results, with a higher risk among patients with persistent villous atrophy. Follow-up biopsy may effectively stratify patients with CD by risk for subsequent LPM.

TABLE 3 Biomarkers in the Diagnosis of Celiac Disease and Monitoring Compliance to Gluten-Free Diet

Biomarker	Method	Comments
Antireticulin antibodies—IgG/IgA	IFA (rat kidney)	Lack optimal sensitivity and specificity for routine diagnostic use
Total IgA	Quantitative nephelometry	Useful in ruling out IgA deficiency; specific IgG antibodies need to be tested in IgA-deficient individuals
Antigliadin antibodies—IgG/IgA	Quantitative EIA	Low sensitivity and specificity; useful in monitoring dietary compliance
Antideaminated gliadin antibodies—IgG/IgA	Quantitative EIA	Inferior performance relative to other diagnostic assays
Antiendomysial antibodies—IgG/IgA	IFA (rhesus monkey esophagus; human umbilical cord)	High sensitivity and specificity in CD; observer bias limits usefulness
Antitissue glutaminase—IgG/IgA	Quantitative EIA	Assays using purified human or recombinant human tTG are more sensitive than those using guinea pig tTG; useful in both diagnosis and monitoring dietary compliance
HLA-DQ2/HLA-DQ8	PCR-based assays	High negative predictive value; not affected by dietary gluten; found in ≈30% of general population

CD, Celiac disease; *EIA,* enzyme immunoassay; *IFA,* immunofluorescence; *IgA,* immunoglobulin A; *IgG,* immunoglobulin G; *PCR,* polymerase chain reaction; *tTG,* tissue transglutaminase.

TABLE 4 Sensitivity, Specificity, and Positive and Negative Predictive Values of Serologic Tests for Untreated Celiac Disease

Serologic Test	Sensitivity* (%)	Specificity* (%)	Positive Predictive Value (%)	Negative Predictive Value (%)
Immunoglobulin A Tissue Transglutaminase				
Endomysial antibody by indirect immunofluorescence assay	85-98	97-100	98-100	80-95
Guinea pig tTG ELISA	95-98	94-95	91-95	96-98
Human tTG ELISA	95-100	97-100	80-95	100
Antigliadin Antibodies (AGAs)				
IgA	75-90	82-95	28-100	65-100
IgG	69-85	73-90	20-95	41-88

AGA, Antigliadin antibodies; *ELISA,* enzyme-linked immunosorbent assay; *IgA,* immunoglobulin A; *IgG,* immunoglobulin G; *tTG,* tissue transglutaminase.
*Wide variations in test sensitivity and specificity rates are reported among different laboratories. (Stern M: Comparative evaluation of serologic tests for celiac disease: a European initiative toward standardization, *J Pediatr Gastroenterol Nutr* 31:513-519, 2000.)
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

BOX 2 Principles of Initial Dietary Therapy for Patients with Celiac Disease

Avoid all foods containing wheat, rye, and barley gluten (pure oats usually safe).

Avoid malt unless clearly labeled as derived from corn.

Use only rice, corn, maize, buckwheat, millet, amaranth, quinoa, sorghum, potato or potato starch, soybean, tapioca, and teff, bean, and nut flours.

Wheat starch and products containing wheat starch should only be used if they contain less than 20 ppm gluten and are marked "gluten free."

Read all labels and study ingredients of processed foods.

Beware of gluten in medications, supplements, food additives, emulsifiers, or stabilizers.

Limit milk and milk products initially if there is evidence of lactose intolerance.

Avoid all beers, lagers, ales, and stouts (unless labeled gluten free).

Wine, most liqueurs, ciders, and spirits, including whiskey and brandy, are allowed.

ppm, Parts per million.
Modified from Trier JS: Celiac sprue and refractory sprue. In Feldman M, Scharschmidt BF, Sleisenger MH (eds): *Gastrointestinal and liver disease,* ed 6, Philadelphia, 1997, WB Saunders, p 1557. In Feldman M et al: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

PEARLS & CONSIDERATIONS

COMMENTS

- The presence of dermatitis herpetiformis is pathognomonic for celiac disease.
- In close relatives, repeated serum tTG IgA testing may be useful in those with positive *HLA-DQ2* or *HLA-DQ8* tests because celiac disease may not manifest until later in life, and initial negative results do not preclude the possibility of future onset of celiac disease.
- Celiac disease should be considered in patients with unexplained metabolic bone disease, osteoporosis, transaminasemia, or hypocalcemia, because gastrointestinal symptoms are absent or mild. Clinicians should also consider testing children and young adults for celiac disease if unexplained weight loss, abdominal pain or distention, or chronic diarrhea is present.
- Screening for celiac disease is recommended in first-degree relatives. It should also be considered in patients with type 1 diabetes mellitus and in those with certain autoimmune disorders such as primary biliary cirrhosis, primary sclerosing cholangitis, autoimmune hepatitis, IBD, thyroid disease (hypothyroidism occurs in up to 15% of patients with celiac disease), systemic lupus erythematosus, RA, and Sjögren syndrome due to increased risk of celiac disease in these populations. Screening persons with Down syndrome or Turner syndrome has also been recommended.
- The prevalence of celiac disease in patients with dyspepsia is twice that of the general population. Screening for celiac disease should be considered in all patients with persistent dyspepsia.
- Patients with celiac disease have an overall risk of cancer that is almost twice that of the general population. The risk of adenocarcinoma of the small intestine is increased manifold compared with the risk in the general population. Celiac disease is also associated with an increased risk for non-Hodgkin lymphoma, especially of T-cell type and primarily localized in the gut. Lymphoma is 4 to 40 times more common, and death from lymphoma is 11 to 70 times more common in patients with celiac disease.
- Patients with celiac disease who have followed a gluten-free diet for prolonged periods may not experience relapse of symptoms for several months after gluten is reintroduced.
- Trials involving randomized feeding intervention in infants at high risk for celiac disease have shown that as compared to placebo, the introduction of small quantities of gluten at 16 to 24 weeks of age did not reduce the risk of celiac disease by 3 yr of age.

BASIC INFORMATION

DEFINITION

Cellulitis is an infection of the deep dermis and subcutaneous tissues characterized by erythema, warmth, and tenderness of the involved area. Diagnosis is made on the basis of history and physical examination.

SYNONYMS

Erysipelas (cellulitis generally caused by group A β-hemolytic streptococci [GABHS])
SSSIs (skin and skin structure infections)
ABSSSIs (acute bacterial skin and skin structure infections)

ICD-10CM CODES

H05.011	Cellulitis of right orbit
H05.012	Cellulitis of left orbit
H05.013	Cellulitis of bilateral orbits
H05.019	Cellulitis of unspecified orbit

L03.811	Cellulitis of head [any part, except face]
L03.818	Cellulitis of other sites
L03.90	Cellulitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Occurs most frequently in diabetics, immunocompromised hosts, and patients with venous and lymphatic compromise.
- Frequently found near skin breaks (trauma, surgical wounds [surgical site infections develop in 2% to 5% of all surgical procedures], ulcerations, tinea infections). Edema, animal or human bites, subadjacent osteomyelitis, and bacteremia are potential sources of cellulitis.
- Skin and soft-tissue infections account for >14 million outpatient visits per yr and $3.7 billion in ambulatory care costs. They also are responsible for more than 650,000 admissions in the U.S./yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Variable with the causative organism:

- Erysipelas (Fig. E1): Superficial-spreading, warm, erythematous lesion distinguished by indurated, elevated margin; lymphatic involvement, vesicle formation common.
- Staphylococcal cellulitis: Area involved is erythematous, hot, and swollen; differentiated from erysipelas by nonelevated, poorly demarcated margin; local tenderness and regional adenopathy are common; up to 85% of cases occur on the legs and feet.
- *Haemophilus influenzae* cellulitis: Area involved is a blue-red/purple-red color; occurs mainly in children; generally involves the face in children and the neck or upper chest in adults.
- *Vibrio vulnificus:* Larger hemorrhagic bullae, cellulitis, lymphadenitis, myositis; often found in critically ill patients in septic shock.
- Table 1 describes anatomic variants of or predispositions to cellulitis. Typically, nonpurulent cellulitis is caused by β-hemolytic streptococci, whereas cellulitis with purulent drainage is caused by MRSA.

ETIOLOGY

- Any disruption of the skin barrier provides a portal for pathogens to enter the skin and soft tissues.
- Group A β-hemolytic streptococci (may follow a streptococcal infection of the upper respiratory tract). β-hemolytic streptococci are implicated in most cases of nontraumatic cellulitis.
- Staphylococcal cellulitis: Diabetics, athletes, men who have sex with men, people living in public housing, and incarcerated men are at greater risk for methicillin-resistant *Staphylococcus aureus* (MRSA) infection. A community-acquired MRSA strain, USA 300, is replacing nosocomial strains of MRSA in hospitals.
- IV drug use: MRSA, *Pseudomonas aeruginosa.*
- *V. vulnificus:* Higher incidence in patients with liver disease (75%) and in immunocompromised hosts. *V. vulnificus* infection is the leading cause of death related to seafood consumption in the U.S.
- *Erysipelothrix rhusiopathiae:* Common in people handling poultry, fish, or meat.
- *Aeromonas hydrophila:* Generally occurs in contaminated open wounds in fresh water.
- Fungi *(Cryptococcus neoformans):* In immunocompromised granulopenic patients.
- Gram-negative rods *(Serratia, Enterobacter, Proteus, Pseudomonas):* May be present in immunocompromised or granulopenic patients.
- Hot tub exposure: *P. aeruginosa*; fish tank exposure: *Mycobacterium marinum.*
- Bites: Human *(Eikenella corrodens),* dog *(Pasteurella multocida, C. canimorsus),* cat *(P. multocida),* rat *(Streptobacillus moniliformis).*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Necrotizing fasciitis (reddish-purple discoloration of skin, rapid increase in size, woody induration and pale appearance rather than erythema, violaceous bullae, pain out of proportion to appearance, sepsis)
- Deep vein thrombosis
- Peripheral vascular insufficiency (venous stasis dermatitis)
- Paget disease of the breast
- Thrombophlebitis
- Acute gout
- Psoriasis
- *Candida* intertrigo
- Pseudogout
- Osteomyelitis
- Insect bite
- Fixed drug eruption
- Lymphedema
- Contact dermatitis
- Olecranon bursa infection
- Herpetic whitlow, early herpes zoster (before blisters)
- Erythema migrans (Lyme disease)
- Rare: *Vaccinia* vaccination, Kawasaki disease, pyoderma gangrenosum, Sweet syndrome, carcinoma erysipeloides, anaerobic myonecrosis, erythromelalgia, eosinophilic cellulitis (Well syndrome), familial Mediterranean fever

LABORATORY TESTS

- Laboratory testing is generally not required for the evaluation of cellulitis and uncomplicated soft tissue infections in the absence of comorbidities
- CBC with differential: Leukocytosis may be present but is a non-specific finding
- Gram stain, culture (aerobic and anaerobic):
  1. Aspirated material from:
     a. Advancing edge of cellulitis
     b. Any vesicles
  2. Swab of any drainage material
  3. Punch biopsy (in selected patients)
- Blood cultures in hospitalized patients, patients with cellulitis superimposed on lymphedema, patients with buccal or periorbital cellulitis, and patients suspected of having a salt- or fresh-water source of infection. Bacteremia uncommon in cellulitis (positive blood cultures in 4% of patients)
- Anti-streptolysin O (ASLO) titer (in suspected streptococcal disease)
- The cause of cellulitis remains unidentified in most patients. Patients with recurrent lower-extremity cellulitis should be inspected for tinea pedis. If found, it should be treated.

IMAGING STUDIES

- Imaging is generally not necessary but may be helpful in suspected purulent soft tissue infections and osteomyelitis.

TABLE 1 Anatomic Variants of or Predispositions to Cellulitis

Anatomic Variant or Predisposition	Location	Likely Bacterial Cause
Periorbital cellulitis	Periorbital	*Staphylococcus aureus, Streptococcus pneumoniae,* group A streptococci
Buccal cellulitis	Cheek	*Haemophilus influenzae* type b
Cellulitis complicating body piercing	Ear, nose, umbilicus	*S. aureus,* group A streptococci
After mastectomy (with axillary node dissection)	Ipsilateral upper extremity	Non–group A β-hemolytic streptococci
After lumpectomy (with limited axillary node dissection, breast irradiation)	Ipsilateral breast	Non–group A β-hemolytic streptococci
After saphenous vein harvest for coronary artery bypass	Ipsilateral leg	Group A or non–group A β-hemolytic streptococci
After radical pelvic surgery, radiation therapy	Vulva, inguinal areas, legs	Group B and group G streptococci
After liposuction	Thigh, abdominal wall	Group A streptococci, peptostreptococci
Postoperative (very early) wound infection	Abdomen, chest, hip	Group A streptococci
Injection drug use ("skin popping")	Extremities, neck	*S. aureus,* streptococci (groups A, C, F, G)*
Perianal cellulitis	Perineum	Group A streptococcus

*Other bacteria to consider based on isolation from skin or abscesses in this setting include *Enterococcus faecalis,* viridans group streptococci, coagulase-negative staphylococci, anaerobes (including *Bacteroides* and *Clostridium* spp.), and Enterobacteriaceae.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

- CT or MRI in patients with suspected necrotizing fasciitis (deep-seated infection of the subcutaneous tissue that results in the progressive destruction of fascia and fat).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Immobilization and elevation of the involved limb. Cool sterile saline dressings to remove purulence from any open lesion. Support stockings in patients with peripheral edema.

ACUTE GENERAL Rx

Treatment should initially cover *Streptococcus* and methicillin-sensitive *S. aureus* and should be expanded for MRSA in patients with risk factors (e.g., IV drug users, residents of long-term care facilities, athletes, children, men who have sex with men, prisoners).

ERYSIPELAS:
- PO: Dicloxacillin 500 mg PO q6h or cephalexin 500 mg qid
- IV: Cefazolin 1 g q6 to 8h or nafcillin 1.0 or 1.5 g IV q4 to 6h

NOTE: Use vancomycin 1 g IV q12h in patients allergic to penicillin.

STAPHYLOCOCCAL CELLULITIS:
- PO: Dicloxacillin 250 to 500 mg qid
- IV: Nafcillin 1 to 2 g q4 to 6h
- Cephalosporins (cephalexin 500 mg qid) also provide adequate antistaphylococcal coverage, except for MRSA.
- Trimethoprim-sulfamethoxazole (160 mg/800 mg 1 PO bid) may be appropriate in outpatient mild MRSA infections. Use vancomycin 1.0 to 2.0 g IV qd or linezolid 0.6 g IV q12h in patients with moderate/severe MRSA. Daptomycin (Cubicin), a cyclic lipopeptide, can be used as an alternative to vancomycin for complicated skin and skin structure infections. Usual dose is 4 mg/kg IV given over 30 min every 24 hr. Telavancin is a new glycopeptide derivative of vancomycin effective for gram-positive skin and skin structure infections, including those caused by MRSA. Tedizolid is an oxazolidinone effective in ABSSSI as an alternative to linezolid. Ceftaroline fosamil (Teflaro) is a newer IV cephalosporin also effective against MRSA. Dalbavancin and tedizolid are two new drugs FDA-approved for skin and skin structure infections, including those caused by MRSA.

H. INFLUENZAE CELLULITIS:
- PO: Cefixime or cefuroxime
- IV: Cefuroxime or ceftriaxone

VIBRIO VULNIFICUS:
- Doxycycline 100 mg IV bid + ceftazidime 2 g IV q8h or IV ciprofloxacin 400 mg bid. Mild cases treated with oral antibiotics (doxycycline 100 mg bid + ciprofloxacin 750 mg bid).
- IV support and admission into intensive care unit (mortality rate >50% in septic shock).

E. RHUSIOPATHIAE:
- Penicillin

A. HYDROPHILA:
- Aminoglycosides
- Chloramphenicol
- Complicated skin and skin structure infections in hospitalized patients can be treated with daptomycin (Cubicin) 4 mg/kg IV q24h

PEARLS & CONSIDERATIONS

- 16.6% of acute cellulitis cases are unresponsive to initial treatment mainly due to inappropriate antibiotic selection and dosing (weight-based dosing is preferred).
- Prophylactic antibiotics (e.g., dicloxacillin 500 mg bid or erythromycin 250 mg bid) are controversial but can be considered with patients with ≥4 episodes of cellulitis despite optimized control of risk factors. Recurrent cellulitis with no identifiable cause occurs in 22% of cases despite antibiotic prophylaxis.
- In patients with uncomplicated cellulitis in the outpatient setting, adding trimethoprim-sulfamethoxazole to cephalexin for MRSA coverage is unnecessary and does not increase the likelihood of clinical cure.

BASIC INFORMATION

DEFINITION

Cerebral palsy (CP) is a group of disorders of the central nervous system characterized by aberrant control of either movement or posture, present since early in life and not the result of a progressive or degenerative disease. Table E1 provides a classification of CP and major causes.

SYNONYMS

Little disease
Congenital static encephalopathy
Congenital spastic paralysis
CP

ICD-10CM CODES

G80.0 Spastic quadriplegic cerebral palsy
G80.1 Spastic diplegic cerebral palsy
G80.2 Spastic hemiplegic cerebral palsy
G80.3 Athetoid cerebral palsy
G80.4 Ataxic cerebral palsy
G80.8 Other cerebral palsy
G80.9 Cerebral palsy, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 2 to 2.5 persons per 1000 live births
PREDOMINANT SEX: Males and females affected equally
PREDOMINANT AGE: Diagnosis typically made at 3 to 5 yr of age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Monoplegia, diplegia, quadriplegia, hemiplegia
- Often hypotonic in newborn period, followed by development of hypertonia
- Spasticity
- Athetosis
- Delay in motor milestones
- Hyperreflexia
- Seizures
- Mental retardation in many individuals

ETIOLOGY

Multifactorial, including low birth weight, congenital malformation, asphyxia, multiple gestation, intrauterine exposure to infection, neonatal stroke, hyperbilirubinemia, and maternal thyroid malfunction

DIAGNOSIS

A motor deficit is always present. The usual presenting complaint is that child is not reaching motor milestones at the appropriate age. Medical history establishes that the child is not losing function (i.e., that deficit is static and not progressive). This history, combined with a neurologic examination establishing that motor deficit is due to a cerebral abnormality, establishes the diagnosis of CP. Serial examinations may be necessary.

DIFFERENTIAL DIAGNOSIS

Other causes of neonatal hypotonia include muscular dystrophies, spinal muscular atrophy, Down syndrome, and spinal cord injuries. Causes of progressive spasticity in children include metabolic diseases involving white matter (e.g., leukodystrophy).

WORKUP

- Laboratory tests are not necessary to establish the diagnosis.
- Workup is helpful for assessment of recurrence risk, implementation of prevention programs, and medicolegal purposes.

LABORATORY TESTS

- Metabolic and genetic testing should be considered if on follow-up the child has the following: (1) evidence of deterioration or episodes of metabolic decompensation, (2) no etiology determined by neuroimaging, (3) family history of childhood neurologic disorder associated with CP, or (4) developmental malformation on neuroimaging. Hypercoagulability workup should be considered if neuroimaging is suggestive of a remote stroke.
- EEG should be obtained when a child with CP has a history suggestive of seizures.
- Children with CP should be screened for ophthalmologic and hearing impairments as well as speech and language disorders. Nutrition, growth, and swallowing function should be monitored.

IMAGING STUDIES

- Neuroimaging is recommended if the etiology has not been established previously, for example, by perinatal imaging.
- MRI, when available, is preferred to CT scanning because of higher yield in determining an etiology and timing of the insult leading to CP.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical therapy, occupational therapy, and speech therapy.
- Orthotics and casting are used to increase musculotendinous length.

ACUTE GENERAL Rx

If present, treatment of seizures

CHRONIC Rx

- Treatment of seizures, as directed by seizure type.
- Medical treatment of spasticity includes baclofen (oral and intrathecal), as well as botulinum toxin A.
- Surgical treatments of spasticity include dorsal rhizotomy, tendon lengthening, and osteotomy.

DISPOSITION

Most children with CP live at home. Those children with severely impaired mobility or other disabilities may live in chronic-care nursing facilities.

REFERRAL

If the child has difficulty with spasticity, physical medicine and rehabilitation referrals are especially helpful.

TABLE E1 Classification of Cerebral Palsy and Major Causes

Motor syndrome (Approx. % of CP)	Neuropathology/MRI	Major Causes
Spastic diplegia (35%)	Periventricular leukomalacia Periventricular cysts or scars in white matter, enlargement of ventricles, squared-off posterior ventricles	Prematurity Ischemia Infection Endocrine/metabolic (e.g., thyroid)
Spastic quadriplegia (20%)	Periventricular leukomalacia Multicystic encephalomalacia Cortical malformations	Ischemia, infection Endocrine/metabolic, genetic/developmental
Hemiplegia (25%)	Stroke: in utero or neonatal Focal infarct or cortical, subcortical damage Cortical malformations	Thrombophilic disorders Infection Genetic/developmental Periventricular hemorrhagic infarction
Extrapyramidal (athetoid, dyskinetic) (15%)	Asphyxia: symmetric scars in putamen and thalamus Kernicterus: scars in globus pallidus, hippocampus Mitochondrial: scarring of globus pallidus, caudate, putamen, brainstem No lesions: ? dopa-responsive dystonia	Asphyxia Kernicterus Mitochondrial Genetic/metabolic

CP, Cerebral palsy; *MRI,* magnetic resonance imaging. From Kliegman RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

PEARLS & CONSIDERATIONS

- In full-term infants, there is usually no history of traumatic delivery.
- Compared with delivery at 40 wks' gestation, delivery at 37 or 38 wk or at 42 wk or later was associated with an increased risk of CP.

Cerebral Vasculitis

BASIC INFORMATION

DEFINITION

Cerebral vasculitis refers to a group of heterogeneous disorders characterized by pathologic inflammation and leukocytoclastic changes in the blood vessel walls.

SYNONYMS

Primary angiitis of the central nervous system (PACNS)
Central nervous system angiitis
Cerebral arteritis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 2.4 cases per 1,000,000 person-yr for PACNS
PEAK INCIDENCE: Fourth decade of life for PACNS
PREDOMINANT SEX: Males are affected twice as often as females by PACNS. For secondary vasculitis of the CNS, sex predominance varies by underlying autoimmune condition.
PREDOMINANT AGE: Usual age of presentation of PACNS is in the third and fourth decades of life, but it can present in age ranging from 17 to 70 yr.
GENETICS: Multifactorial
RISK FACTORS: Infections, connective tissue disorders, systemic vasculitis, and substance abuse are the prominent risk factors for secondary cerebral vasculitis. No risk factors have been clearly established for PACNS.
CLASSIFICATION:

- PACNS (see Table E1 for full diagnostic criteria): Involvement of the blood vessels in brain or spinal cord without involvement of blood vessels and organs beyond the CNS.
- Secondary CNS vasculitis: Involvement of the brain or spinal cord blood vessels by a systemic disorder such as systemic vasculitis, connective tissue disorders, infections, malignancy, or substance abuse.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presentation of cerebral vasculitis is diverse and includes the following:
  1. Nonspecific symptoms such as insidious headache, weight loss, lethargy, personality changes, delirium, and even dementia.
  2. Focal neurologic manifestations: Seen in 80% of patients during course of illness, may mimic multiple sclerosis, with a relapsing and remitting course.
  3. Stroke can occur in 40% of the patients; transient ischemic attacks have been reported in 30% to 50% of patients.
  4. Seizures occur in 25% of patients.
  5. Other common presentations include intracerebral hemorrhage (11%) and intracranial space-occupying lesions (15%).
- Secondary vasculitis often presents with strokelike symptoms. Sjögren syndrome and Behçet disease can have varied presentations that mimic multiple sclerosis, seizures, movement disorders, encephalopathy, dementia, and aseptic meningitis.

ETIOLOGY

The exact etiology of primary cerebral vasculitis is unknown. It has been associated with various infectious agents such as herpes zoster, mycoplasma, HIV, and unknown viruses. Amyloid angiopathy has been described with primary cerebral vasculitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (SEE TABLE E2 FOR COMPLETE DIFFERENTIAL DIAGNOSIS)

- Reversible cerebral vasoconstriction syndrome (RCVS) (see Table E3 for full diagnostic criteria)
- Intracranial artery atherosclerosis
- Cerebral emboli of multiple etiologies
- Intravascular lymphoma
- Sarcoidosis
- Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL)
- Meningovascular syphilis
- Angioinvasive fungal infections
- Varicella zoster virus vasculopathy
- Tuberculosis meningitis vasculopathy

WORKUP

Brain biopsy (lesional area on MRI preferred but if not surgically feasible, then usually nondominant temporal lobe tip along with overlying leptomeninges) is the gold standard diagnostic method and is required for definitive diagnosis. Vessel histology may be granulomatous, lymphocytic, or necrotizing and will reveal vessel wall damage.

A brain MRI with and without contrast has a sensitivity approaching 100%, although it has a

TABLE E1 Diagnostic Criteria for Primary Angiitis of the CNS

1. The presence of an acquired otherwise unexplained neurologic or psychiatric deficit
2. The presence of either classic angiographic or histopathologic features of angiitis within the CNS
3. No evidence of systemic vasculitis or any disorder that could cause or mimic the angiographic or pathologic features of the disease

Hajj-Ali RA, Calabrese LH: Diagnosis and classification of central nervous system vasculitis, *J Autoimmun* 48-49:149-152, 2014.

TABLE E2 Differential Diagnosis of PACNS

Systemic vasculitides	Behçet syndrome, polyarteritis nodosa, granulomatosis with polyangiitis
Systemic inflammatory diseases	Systemic lupus erythematosus, Sjögren syndrome, Crohn disease, sarcoid granulomatosis, and angiitis
Infections	Viral (e.g., herpes zoster, HIV), bacterial (e.g., tuberculosis, syphilis, neuroborreliosis), fungal (e.g., aspergillosis, nocardiosis, *Cryptococcus,* histoplasmosis)
Conditions with cerebral angiographic abnormalities	Reversible cerebral vasoconstriction syndrome, premature intracranial atherosclerosis, fibromuscular dysplasia, moyamoya disease and syndrome, small-vessel arterial dissection, angiotropic and intervascular lymphoproliferative disorders, radiation vasculopathy
Brain diseases with MRI lesions that can mimic PACNS	Brain neoplasms (e.g., intravascular lymphoma, gliomatosis cerebri), genetic conditions (e.g., CADA-SIL, HERNS, COL4A1 mutation), posterior reversible encephalopathy syndrome, Susac syndrome, chronic hypertension ("microvascular cerebral ischemia"), demyelinating diseases (e.g., multiple sclerosis, acute disseminated encephalomyelitis, progressive multifocal leukoencephalopathy)
Miscellaneous	Hyperhomocystinemia, thrombocytic purpura, porphyria, antiphospholipid antibody syndrome, Kohlmeier-Degos
Conditions with multifocal cerebral thromboembolism	Atrial fibrillations and cholesterol atheroembolism, endocarditis, left atrial myxoma and other cardiac tumors

CADA-SIL, Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy; *EGPA,* eosinophil granulomatosis with polyangiitis; *HERNS,* hereditary endotheliopathy with retinopathy, nephropathy, and stroke; *HIV,* human immunodeficiency virus *PACNS,* primary angiitis of the central nervous system.
Hajj-Ali RA, Calabrese LH: Diagnosis and classification of central nervous system vasculitis, *J Autoimmun* 48-49:149-152, 2014.

TABLE E3 Diagnostic Criteria for RCVS

1. Severe and acute headache (often thunderclap) with or without focal deficits or seizures
2. Direct or indirect angiography documenting multifocal segmental cerebral artery vasoconstriction
3. No evidence of aneurysmal subarachnoid hemorrhage
4. Normal or near-normal CSF (protein concentrations)

CSF, Cerebrospinal fluid; *RCVS,* reversible cerebral vasoconstriction syndrome.
From Hajj-Ali RA, Calabrese LH: Diagnosis and classification of central nervous system vasculitis, *J Autoimmun* 48-49:149-152, 2014.

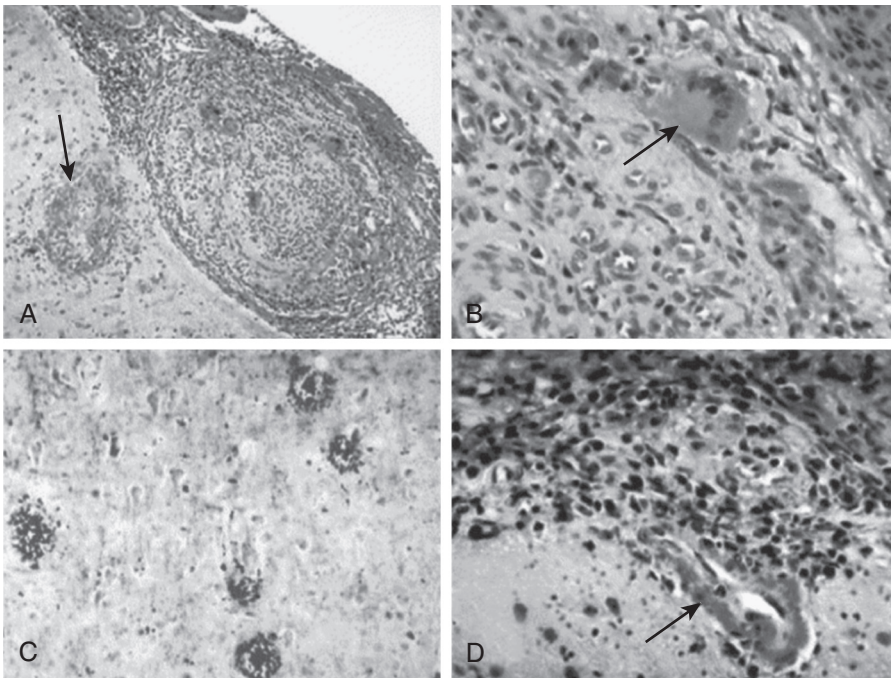

FIG. E1 **A,** Low-power hematoxylin and eosin stain (10×) demonstrates diffuse inflammation in the leptomeninges with infiltration of lymphocytes, eosinophils, and macrophages with destruction of the vessel wall *(arrow).* **B,** A multinucleated giant cell *(arrow).* **C,** Multiple neuritic plaques are seen on this silver stain. **D,** Congo red stain demonstrating the presence of amyloid within a vessel wall *(arrow).* (From Jacobs DA et al: Primary central nervous system angiitis, amyloid angiopathy and Alzheimer's pathology presenting with Balint's syndrome, *Surv Ophthalmol* 49[4]:454-459, 2004.)

very low specificity. Thus, a normal brain MRI virtually excludes the diagnosis of cerebral vasculitis. The most common lesions are ischemic strokes, occurring in 53% of cases. Strokes are often multiple and bilateral, affecting different vascular territories of variable sizes and in various stages of evolution; they can involve the cortex, subcortical areas, and leptomeninges. High-intensity T2-weighted subcortical lesions are very common but not specific. Mass lesions are seen in 5%, meningeal enhancement in 8%, and intracranial hemorrhages in 9% of cases.

Cerebral angiography, either by direct four-vessel angiography or by indirect magnetic resonance or CT angiography, may show beading: diffuse, bilateral, and alternating areas of stenosis and dilation. This finding may indicate vasculitis, but it is not specific for vasculitis. Other nonspecific angiographic findings in CNS vasculitis include tapering of the lumen of a single vessel or many vessels and fusiform arterial dilations, multifocal vascular occlusions, development of collateral circulation, or delayed contrast-medium enhancement and washout time. Furthermore, the resolution of angiography further limits its sensitivity in that it does not capture morphologic changes in small arteries and arterioles, so a cerebral vasculitis limited to these small-caliber vessels will be normal on angiography (Fig. E1).

LABORATORY TESTS

- Lumbar puncture: Cerebrospinal fluid (CSF) should show elevated protein, lymphocytic pleocytosis, and negative microbial cultures. Opening pressure may be elevated. Consider obtaining CSF cytology and flow cytometry.
- Basic laboratory testing: Should include CBC with differential, blood urea nitrogen and serum creatinine, hepatic functions and enzymes, erythrocyte sedimentation rate (ESR), RPR (for syphilis), HIV, C-reactive protein (CRP), and urinalysis with microscopy to look for signs of renal vasculitis. ESR and CRP are typically normal in PACNS.
- Specific serologic tests to evaluate for systemic autoimmune causes: ANA, rheumatoid factor, anti–double-stranded DNA, anti SS-A, anti SS-B, anti–neutrophil cytoplasmic antibodies (both c-ANCA and p-ANCA), complement 3 and 4, cryoglobulins, and testing for HIV, hepatitis B (associated with polyarteritis nodosa), and hepatitis C (associated with mixed cryoglobulinemia). Markers of systemic autoimmune diseases are typically negative in PACNS.
- Echocardiogram and cardiac telemetry should exclude cardioembolic sources such as atrial fibrillation, cardiac thrombus, and atrial myxoma.
- Consider screening for lymphoma in patients with PACNS, since both Hodgkin and non-Hodgkin lymphoma have an association with PACNS.

IMAGING STUDIES

Brain MRI with and without contrast is the neuroimaging of choice. Abnormal findings are seen in virtually 100% of the patients. Cerebral cortex and deep white and gray matter changes are commonly reported (Fig. E2). Angiography has poor sensitivity at detecting small vessel changes. Many patients, in fact, have a normal angiogram, and a vasculopathic appearance of intracerebral vessels on a four-vessel cerebral angiogram does not by itself distinguish an inflammatory vasculitis from a noninflammatory vasculopathy like RCVS (see Table E3 for RCVS diagnostic criteria and Table E4 for features distinguishing PACNS and RCVS).

Rx TREATMENT

There are no randomized controlled trials evaluating treatment of cerebral vasculitis. Treatment strategies are similar to those for systemic vasculitis.

NONPHARMACOLOGIC THERAPY

Patients with permanent deficits are provided with physical and occupational therapy.

ACUTE GENERAL Rx

Steroids: For suspected cases, empiric therapy with glucocorticoids is started after exclusion of infectious causes. Intravenous methylprednisolone 1 g daily for 3 days is preferred, followed by oral therapy for chronic therapy.

CHRONIC Rx

- Steroids: Oral prednisone is continued at high dose (1 mg/kg/day) for 4 to 6 wk and then tapered slowly over 12 mo.
- Immunosuppressive treatment: Pulse intravenous cyclophosphamide or oral cyclophosphamide should be used in addition to steroids for 3 to 6 mo to induce remission. When stable, milder and relatively safer immunosuppressants such as azathioprine, methotrexate, or mycophenolate are used for 2 to 3 yr.

DISPOSITION

Course and prognosis of the disease are variable and depend on the extent of neurologic involvement, severity of deficits, and response to treatment. Neurologic deficits may resolve acutely, slowly, or not at all. Some patients have symptomatic improvement with resolution of headache or altered mental status. Some have improvement in laboratory values, and others have improved MRI scans.

REFERRAL

- Neurologic consultation is indicated in patients with neurologic deficits of uncertain etiology, younger age, intractable headaches, or uncertain diagnosis.
- Neurosurgery consultation for brain biopsy is indicated for definitive tissue-based diagnosis.
- Interventional neuroradiology consultation is indicated for four-vessel cerebral angiogram.
- Rheumatology consultation is indicated when either a systemic vasculitis or connective tissue disease is suspected.
- Infectious diseases consultation is recommended when infection is suspected.

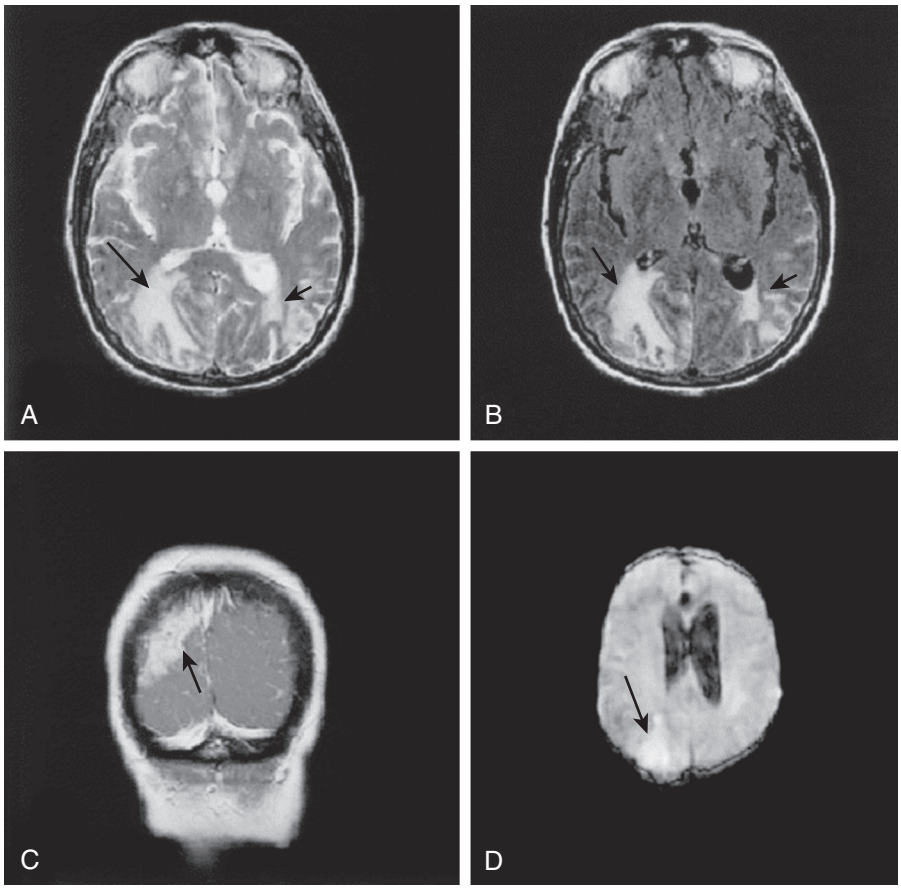

FIG. E2 A, Axial T2-weighted image shows abnormal signal in bilateral parietooccipital lobes, greater on the right than left *(arrows).* **B,** Axial fluid attenuated inversion recovery image further delineating the extent of bilateral parietooccipital lesions *(arrow).* **C,** Coronal T1-gadolinium study demonstrating nodular leptomeningeal enhancement in the lesion *(arrow).* **D,** Diffusion-weighted magnetic resonance imaging shows bright signal in the right parietooccipital region, suggesting ischemic changes *(arrow).* (From Jacobs DA et al: Primary central nervous system angiitis, amyloid angiopathy and Alzheimer's pathology presenting with Balint's syndrome. *Surv Ophthalmol* 49[4]:454-459, 2004.)

TABLE E4 Differentiating Features between PACNS and RCVS

	PACNS	RCVS
Gender, mean age at onset	Male, 50 yr	Female, 42 yr
Headache	Insidious subacute onset	Acute onset, often thunderclap
Clinical course	Chronic, relapsing	Monophasic
CSF findings	Lymphocytic pleocytosis and elevated protein	Normal
MRI of brain	Abnormal in 100% ischemic, high-intensity T2/FLAIR lesions	Normal MRI in 20% ischemia, edema, cSAH, ICH
Cerebrovascular abnormalities	Frequently irreversible	Reversible
Histological findings on brain biopsy	Vasculitic changes	No vasculitic pattern

cSAH, Convexity subarachnoid hemorrhage; *CSF,* cerebrospinal fluid; *FLAIR,* fluid-attenuated inversion recovery; *ICH,* intracranial hemorrhage; *MRI,* magnetic resonance imaging; *PACNS,* primary angiitis of the central nervous system; *RCVS,* reversible cerebral vasoconstriction syndrome.

Hajj-Ali RA, Calabrese LH: Diagnosis and classification of central nervous system vasculitis, *J Autoimmun* 48-49:149-152, 2014.

PEARLS & CONSIDERATIONS

COMMENTS

- Cerebral vasculitis is a rare disorder that is difficult to diagnose because of variable presentation.
- Early recognition of the clinical symptoms and signs is important to prevent long-term morbidity and mortality.
- Systemic, infectious, and noninflammatory vasculopathic (like RCVS) causes should be excluded.
- Patients may need chronic immunosuppressive treatment.

RELATED CONTENT

Vasculitis, Systemic (Related Key Topic)

AUTHORS: **Chloe Mander Nunneley, MD,** and **Joseph S. Kass, MD, JD, FAAN**

BASIC INFORMATION

DEFINITION

Tearing between the layers of the wall of an artery in the neck.

SYNONYMS

Carotid artery dissection
Vertebral artery dissection

ICD-10CM CODES
177.71 Dissection of carotid artery
177.74 Dissection of vertebral artery

EPIDEMIOLOGY & DEMOGRAPHICS

The most common cervical artery dissection (CAD) is the internal carotid; the vertebral artery is less commonly affected. The tearing of the wall can cause clot formation, leading to stroke, especially in young patients. CAD can happen intracranially (most often) or extracranially (rare but worse prognosis).

INCIDENCE: The average annual incidence rate for CAD is reported at 2.6 per 100,000 population; however, the true incidence is likely higher because many cases have self-limited clinical symptoms and remain undiagnosed.

PREVALENCE: Prevalence may reach 15% in the young adult stroke population.

PREDOMINANT SEX AND AGE: Carotid artery dissections are most commonly found in young adults. The mean age for extracranial internal carotid artery dissection is 40 yr. Intracranial dissections are more common in those aged 20 to 30 yr.

GENETICS: Marfan syndrome, type IV Ehlers-Danlos syndrome, cystic medial necrosis, and the *677TT* genotype of the 5,10-methylenetetrahydrofolate reductase gene (*MTHFR 677TT*) have been reported in association with CAD.

RISK FACTORS:

- Seasonality: 58% more patients experience a cervical artery dissection during autumn and winter for unknown causality.
- Vascular factors: Hyperhomocysteinemia is strongly associated with CAD, especially if homocysteine levels are >12 micromols/L
- Chiropractic manipulations are often listed as risk factors, with multiple case reports, although evidence is lacking
- Major cervical trauma: Hyperextension or rotation of the neck
- Although evidence is less strong, infection and migraine may also predispose to CAD, as well
- Arterial wall intrinsic factors, such as arteriopathies, may predispose to arterial dissection after trivial trauma. Angiographic evidence of fibromuscular dysplasia has been noted in 10% to 15% of patients

PHYSICAL FINDINGS & CLINICAL PRESENTATION

A young adult with nuchal rigidity, neck pain, and severe occipital headache after minor head or neck trauma is a common presentation. Focal neurologic symptoms follow as a result of ischemia and may include:

- Ipsilateral facial pain and numbness: Most common focal neurologic complaints
- Contralateral loss of pain and temperature sensation in the trunk and limbs
- Loss of taste, hiccups, vertigo, dysphagia, Horner syndrome, unilateral hearing loss, or tinnitus may also occur
- In contrast to younger patients, those over 60 rarely report mechanical triggers or pain

PATHOPHYSIOLOGY

Arterial wall tears happen either spontaneously or as a result of minor trauma. The tear allows arterial blood under pressure to leak into the wall, creating either a hematoma or a false lumen. Sometimes the tear is subintimal, whereas other times it is subadventitial. Subintimal tears usually result in stenosis of the arterial lumen, whereas subadventitial dissection tends to cause arterial dilation.

ETIOLOGY

Cervical artery dissections may be spontaneous or traumatic. The majority of cases involve minor trauma.

DIAGNOSIS

- Ultrasonography: Safe and accurate; however, it has a 31% false negative result in patients with CAD presenting with Horner syndrome
- CT angiography (Fig. E1)
- Conventional angiography
- MRA (Fig. E2) is the gold standard for diagnosis

DIFFERENTIAL DIAGNOSIS

- Cervical spine fracture
- Cluster headache
- Subarachnoid hemorrhage
- Hypoglycemia
- Stroke/transient ischemic attack (TIA)
- Migraine headache
- Other neck trauma

WORKUP

- Labs not usually required except for determination of renal status for contrast use and coagulation panel. Obtaining blood products may also be necessary in cases of planned surgical intervention (type and cross/match).
- Imaging studies such as ultrasound, conventional angiography, CT angiogram, or magnetic resonance angiography (MRA) give the ultimate diagnosis. The high false-negative rate in ultrasound limits its utility, and the high complication rate and unavailability of conventional angiography limit its widespread use.

TREATMENT

- Cervical spine immobilization is the first step in the setting of any neck trauma.
- Initial noncontrast CT of the cervical spine should be ordered to rule out fracture if suspected; if negative, follow up with CT angiography or MRA.
- Anticoagulation therapy should be performed if there is no contraindication or high risk. First one must rule out intracranial hemorrhage and other bleeding source in trauma patients. Anticoagulation with heparin followed by warfarin is generally accepted as sufficient management for prevention of thromboembolic events.
- In the case of contraindications to anticoagulation therapy, antiplatelet therapy may be used.

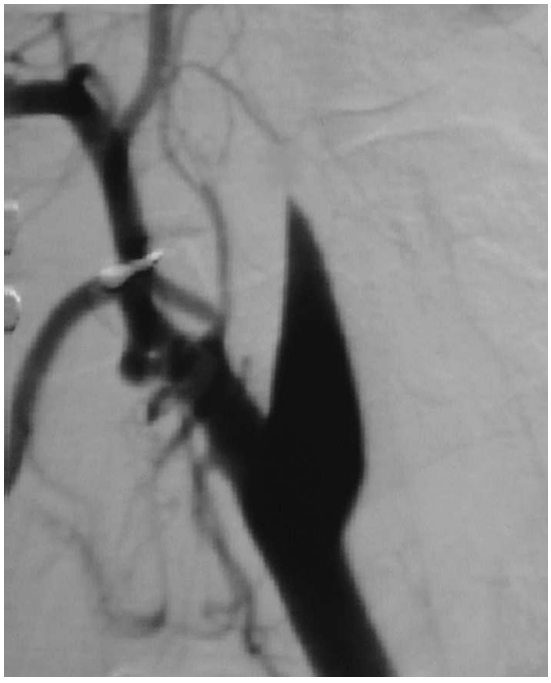

FIG. E1 Acute dissection. A digital subtraction angiogram shows sharply tapered occlusion of the internal carotid artery as a result of spontaneous dissection. (From Soto JA, Lucey BC: *Emergency radiology, the requisites*, ed 2, Philadelphia, 2017, Elsevier.)

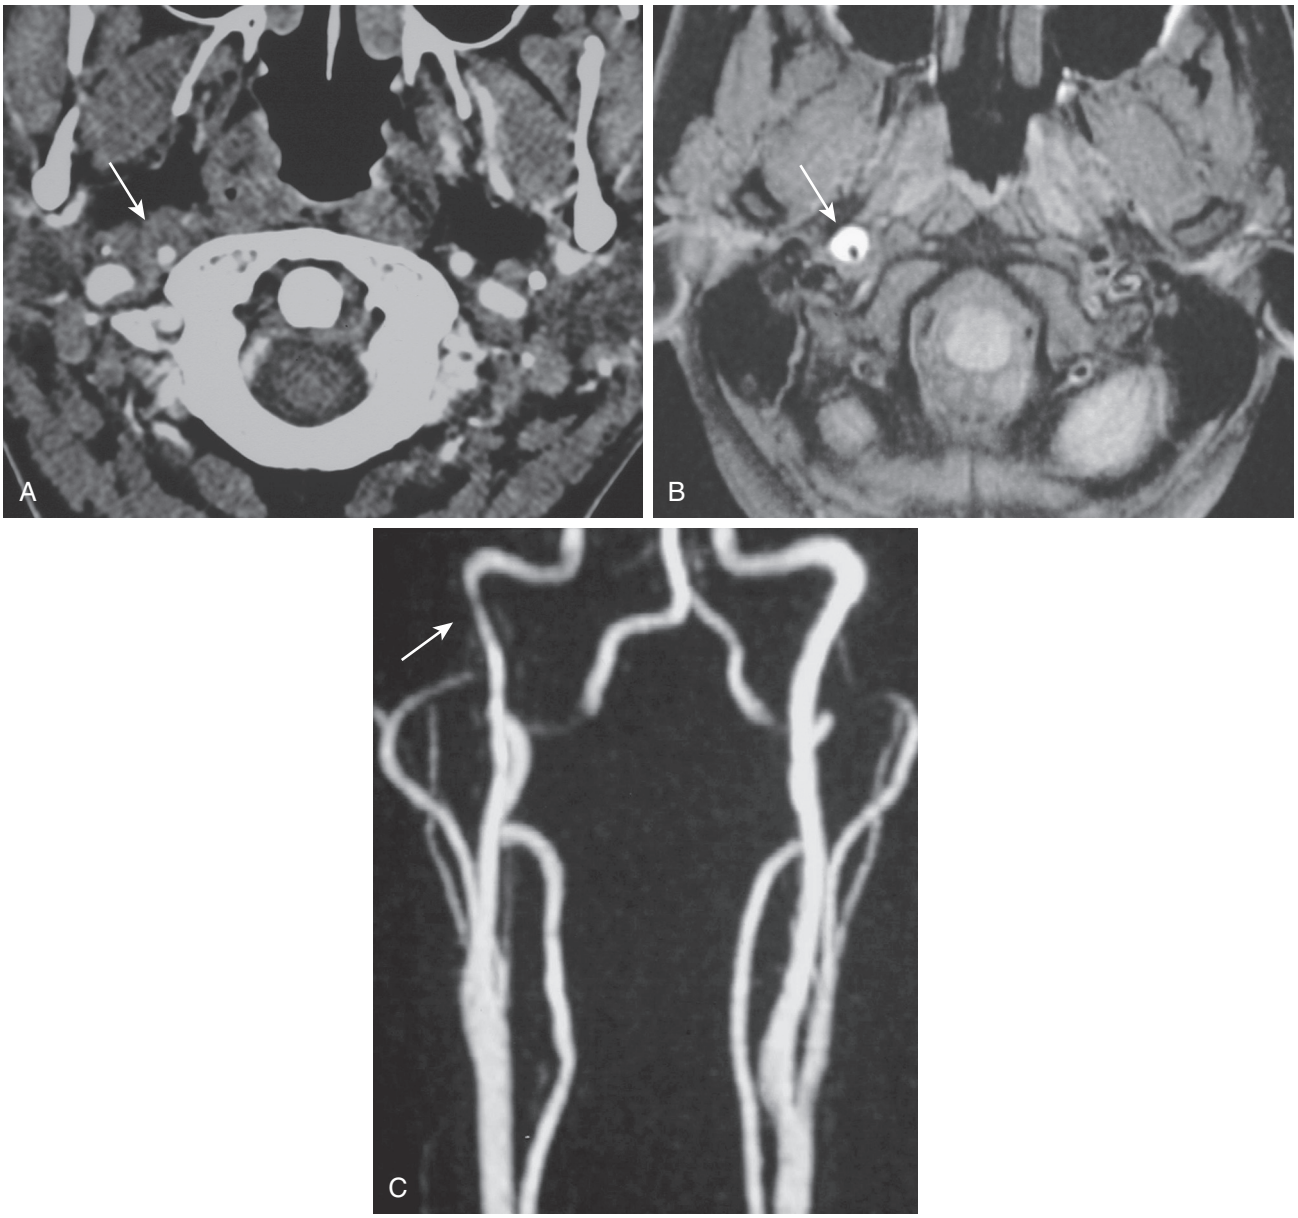

FIG. E2 Internal carotid artery dissection as seen on computed tomography (CT) and magnetic resonance (MR) angiogram. A, A CT angiogram source image shows a narrowed upper cervical right internal carotid artery lumen with an increase in the external caliber of the vessel *(arrow)*. **B,** A fat-suppressed T1-weighted image shows corresponding narrowed flow void with a hyperintense eccentric intramural hematoma *(arrow)*. **C,** A time-of-flight MR angiogram shows a narrowed segment of the right internal carotid artery *(arrow)*. (From Soto JA, Lucey BC: *Emergency radiology, the requisites*, ed 2, Philadelphia, 2017, Elsevier.)

- Do not use anticoagulation or antiplatelet therapy in a pregnant patient without an OB consultation.
- Other pharmacologic treatment modalities are currently in clinical trials.

NONPHARMACOLOGIC THERAPY

Operative endovascular management with angioplasty or stent placement is only utilized in select patients. Criteria include:

- Persistent ischemic symptoms despite adequate anticoagulation
- Contraindication to anticoagulant therapy
- An iatrogenic dissection developing during an intravascular procedure
- Significantly compromised cerebral blood flow

Surgery has limited use in CAD, although surgical consultation is recommended.

DISPOSITION

- Traumatic dissections: Admit to trauma unit with vascular service input.
- Spontaneous dissections: Admit to stroke service and potentially refer to vascular if endovascular intervention is recommended.

REFERRAL

Vascular surgery

COMPLICATIONS

- Occlusion leading to ischemic stroke
- Thrombosis and embolization leading to TIAs
- Subarachnoid hemorrhage if the dissection is intracranial
- Pseudoaneurysm formation

PEARLS & CONSIDERATIONS

In young patients with strokelike symptoms or acute onset neck pain or headache, consider cervical artery dissection.

Traenka C et al: Cervical artery dissection patients ≥60 years: often painless, few mechanical triggers, *Neurology* 88:1313-1320, 2017.

BASIC INFORMATION

DEFINITION

Cervical cancer is the penetration of the basement membrane and infiltration of the stroma of the uterine cervix by malignant cells.

ICD-10CM CODES

C53.8 Malignant neoplasm of overlapping sites of cervix uteri
C53.9 Malignant neoplasm of cervix uteri, unspecified
D06.7 Carcinoma in situ of other parts of cervix
D06.9 Carcinoma in situ of cervix, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: According to the World Health Organization, cervical cancer is the fourth most common malignancy in women. It is reported that nearly 9 out of 10 women who died of cervical cancer were in an underdeveloped region of the world.
PREDOMINANCE: Higher incidence rates occur in developing countries. Among the U.S. population, Hispanics have a higher incidence than African Americans, who likewise have a higher incidence than Caucasians.
RISK FACTORS: Infection with high-risk human papillomavirus (HPV; types 16 and 18 are the most oncogenic with 31, 33, 35, 45, 52, and 58 also considered high risk). Smoking, early age of coitarche, multiple sexual partners, immunocompromised state, nonbarrier methods of contraception, and multiparity are also risk factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Unusual vaginal bleeding, particularly postcoital (Fig.1)
- Vaginal discharge and/or odor
- Pelvic pain in early stage disease. In later stages back pain or disrupted urination or defecation may occur
- Advanced cases may present with lower-extremity edema or renal failure
- In early stages, there may be little or no obvious cervical lesion; more advanced cases may have large, bulky, friable lesions (Fig. E2) encompassing majority of vagina

ETIOLOGY

- Infection with high-risk HPV types is a necessary, although not sufficient, cause of almost all cases of cervical cancer. Persistent HPV infection leads to precancerous changes of the cervix known as cervical intraepithelial neoplasia (CIN). CIN can progress to invasive cervical cancer.
- Both squamous cell and adenocarcinoma of cervix are associated with HPV infection (Table 1).
- More than 40 HPV types can infect the cervix. Most cases are believed to be linked to presence of HPV 16, 18, 31, 35, 39, 45, 51, 52, 56, 58, 59, and 68 by interaction of E6 and E7 oncoprotein on *p53* gene product.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cervical polyp or prolapsed uterine fibroid.
- Neoplasia metastatic from a separate primary neoplasia.
- Box 1 summarizes benign mimics of cervical adenocarcinoma.
- Categories of squamous carcinoma are described in Box 2.
- Table 2 summarizes the differential diagnosis of squamous intraepithelial lesions.

WORKUP

- Thorough history and physical examination
- Pelvic examination with careful rectovaginal examination
- Table 3 summarizes the clinical evaluation of patients with newly diagnosed cervical cancer
- Compared with Pap testing, HPV testing has greater sensitivity for detection of CIN. Addition of HPV test for high-risk types to Pap test to screen women in mid-30s for cervical cancer reduces incidence of grade 2 or 3 CIN or cancer detected by subsequent screening examinations
- Colposcopy with directed biopsy and endocervical curettage
- FIGO staging is described in Table 4

LABORATORY TESTS

- Complete blood count, chemistry profile
- SCC antigen in research setting
- Carcinoembryonic antigen

IMAGING STUDIES

- Chest x-ray
- Depending on stage, may need CT scan, MRI (Fig.E3), PET/CT
- Table 3, intravenous pyelogram

TREATMENT

NONPHARMACOLOGIC THERAPY

- FIGO stage I_A: Cone biopsy or simple hysterectomy
- FIGO stage I_B or II_A: Type III radical hysterectomy and pelvic lymphadenectomy or pelvic radiation therapy. Minimally invasive radical hysterectomy is associated with shorter overall survival than open surgery among women with stage I_{A2} or I_{B2} cervical carcinoma (Melamed A et al, in Suggested Reading N Engl J Med 379:1905, 2018.)
- Advanced or bulky disease: Multimodality therapy (radiation, chemotherapy, and/or surgery); platinum use before radiation therapy

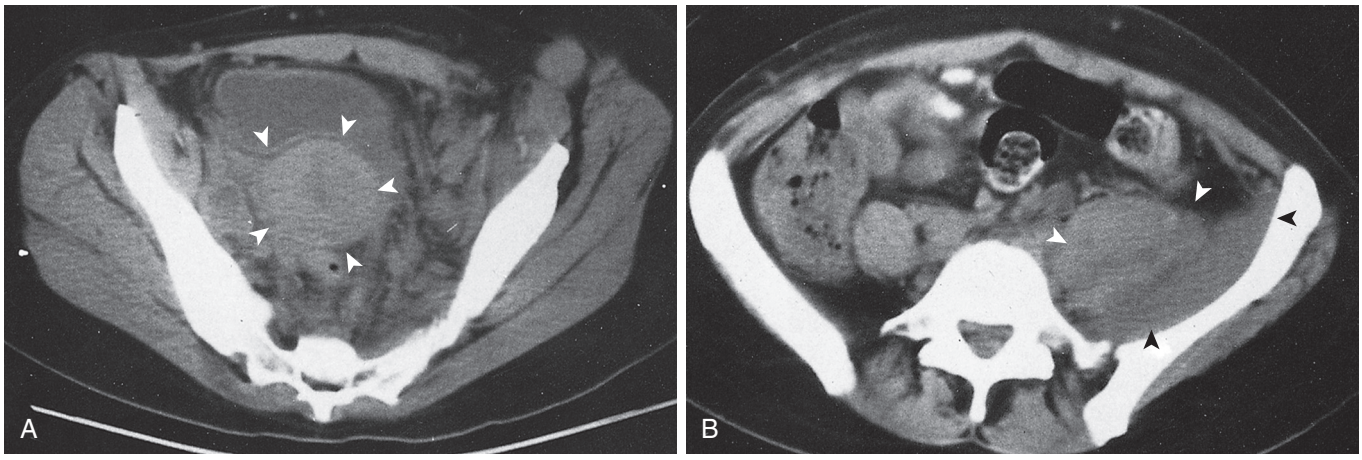

FIG. 1 Stage III_B cervical carcinoma. A 27-year-old woman presented with increased vaginal bleeding, left leg swelling, and abdominal pain. Examination revealed a large, fixed pelvic mass. Computed tomography scan evaluation **(A)** confirms the mass *(arrowheads)* and **(B)** shows extension into the left psoas and iliacus muscles *(arrowheads)*. She also had hydronephrosis. Pathologic examination showed an adenosquamous carcinoma. (From Skarin AT: *Atlas of diagnostic oncology*, ed 4, Philadelphia, 2010, Mosby.)

TABLE 1 Descriptive Categories of Low-Grade Squamous Intraepithelial Lesion and High-Grade Squamous Intraepithelial Lesion

	Descriptors	Human Papillomavirus	p16 Immunostaining
LSIL	CIN1, flat condyloma, mild dysplasia	HR (70%)	Usually diffuse
	Exophytic condyloma	LR	Negative or patchy
	Immature condyloma (papillary immature metaplasia)	LR	Negative or patchy
	Immature flat metaplastic LSIL	HR	Usually diffuse
HSIL	CIN2 or moderate dysplasia	HR (45% type 16)	Diffuse
	CIN3 or severe dysplasia/carcinoma in situ	HR (60% type 16)	Diffuse
	Keratinizing SIL	HR	Diffuse
	HSIL with immature metaplastic phenotype	HR	Diffuse
	Papillary carcinoma in situ	HR	Diffuse
	Adenosquamous carcinoma in situ	HR	Diffuse

CIN, Cervical intraepithelial lesion; *HR,* high risk; *HSIL,* high-grade squamous intraepithelial lesion; *LR,* low risk; *LSIL,* low-grade squamous intraepithelial lesion; *SIL,* squamous intraepithelial lesion.
Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

BOX 1 Benign Mimics of Cervical Adenocarcinoma

Deep nabothian cysts, florid deep glands
Tunnel clusters
Endocervical gland hyperplasias
  Lobular hyperplasia
  Diffuse laminar hyperplasia
Adenomyoma of the endocervical type
Endocervicosis, florid cystic endosalpingiosis
Müllerian papilloma
Microglandular hyperplasia
Mesonephric hyperplasia
Ectopic prostate
Deep tubal metaplasia

Crum CP et al: *Diagnostic gynecologic and obstetric pathology*, ed 3, Philadelphia, 2018, Elsevier.

BOX 2 Categories of Squamous Carcinoma

Squamous cell carcinoma
Large cell keratinizing (well-differentiated)
Large cell nonkeratinizing (moderately differentiated)
Small cell nonkeratinizing (poorly differentiated)
Lymphoepithelial-like carcinoma
Spindle cell (sarcomatoid) carcinoma
Verrucopapillary carcinomas
Papillary (squamotransitional) carcinoma
Verrucous carcinoma (rare)[a]
Condylomatous carcinoma[a]
Basaloid carcinomas[b]

[a]In young women, an extensive (giant) condyloma must be excluded.
[b]May be associated with adenoid basal and adenoid cystic carcinomas, as well as carcinosarcomas.
Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

TABLE 2 Differential Diagnosis of Squamous Intraepithelial Lesions

Category	Mimic	Distinguishing Features
LSIL	Mucosal polyp (vaginal)	Minimal acanthosis, no koilocytosis
	Reactive epithelial changes	Mild superficial karyomegaly, occasional binucleated intermediate cells
	Postmenopausal changes	Superficial cell karyomegaly, cytoplasmic halos
HSIL	Immature reactive/repair	Basal hyperchromasia, uniform nuclear spacing and nuclear contour, nucleoli
	Immature metaplasia	Uniform maturation, minimal surface hyperchromasia
	Atrophy	No mitoses, uniform chromasia, nuclear density
	Atypical atrophy	Enlarged nuclei, uncommon
	Implantation site	Uniform and wide nuclear spacing, bizarre nuclei
	Endometrial histiocytes	Small indented nuclei, granular cytoplasm, lack of polarity

HSIL, High-grade squamous intraepithelial lesion; *LSIL,* low-grade squamous intraepithelial lesion.
Crum CP et al: *Diagnostic gynecologic and obstetric pathology,* ed 3, Philadelphia, 2018, Elsevier.

ACUTE GENERAL Rx

- Table 4 summarizes treatment according to tumor stage. Fig. 4 describes a treatment algorithm for invasive cervical cancer.
- Chemotherapy is cisplatin-based. In advanced cases, cervical cancer may present with massive and acute vaginal bleeding requiring volume and blood replacement, vaginal packing or other hemostatic modalities, and/or high-dose local radiotherapy.

CHRONIC Rx

- Physical examination with Pap smear every 3 mo for 2 yr, every 6 mo for 3 to 5 yr, annually thereafter. Table 5 summarizes a proposed schedule for interval evaluation of cervical cancer after radiotherapy or surgery in asymptomatic patients
- Chest x-ray annually (optional)
- Other imaging done only as clinically indicated
- Localized pelvic recurrence may be treated and cured with pelvic exenteration

DISPOSITION

Five-yr survival varies by stage:
- Stage I: 90% to 95%
- Stage II: 40% to 80%
- Stage III: <60%
- Stage IV: <15%

Early detection by Pap smear is imperative for long-term improvements in survival. American Cancer Society guidelines for screening by cytology for the early detection of cervical neoplasia and cancer are summarized in Table 6.

REFERRAL

Gynecologic oncologist for all invasive disease

PEARLS & CONSIDERATIONS

- HPV vaccination is indicated in males and females age 9 to 26 yr for the prevention of cervical cancer caused by HPV types 6, 11, 16, and 18. HPV vaccination is over 90% effective in preventing infection and cervical cancer. There are now HPV vaccines that are effective against nine strains of high-risk HPV.
- Available evidence supports discontinuation of cervical cancer screening among women aged 65 yr or older who have had adequate screening and are not otherwise at high risk.
- Updated recommendations from the American College of Physicians on screening for cervical cancer in average-risk women are as follows.[1]
  1. Women should be screened with cervical cytology every 3 yr beginning at age 21 until age 30.

[1] Sawaya GF et al: Cervical cancer screening in average-risk women: best practice advice from the Cervical Guidelines Committee of the American College of Physicians, *Ann Intern Med* 162(12):851-859, 2015.

TABLE 3 Clinical Evaluation of Patients with Newly Diagnosed Cervical Cancer

History	Review of Systems	General Physical Examination
Risk factors (STDs, smoking, OCPs, HIV), prior abnormal Pap tests, previous dysplasia, and treatment	Abnormal vaginal bleeding or discharge, pelvic pain, flank pain, sciatica, hematuria, rectal bleeding, anorexia, weight loss, bone pain	Peripheral lymphadenopathy
Evaluation	Common procedures (FIGO)	Alternative procedures
Invasive cancer	Cervical biopsy Endocervical curettage Cervical conization	Histologic diagnosis required
Tumor size; involvement of the vagina, bladder, rectum and parametria	Pelvic examination under anesthesia	MRI of pelvis preferred over CT
Anemia	Complete blood count	—
Renal failure	Serum chemistries	—
Hematuria	Urinalysis	—
Bladder involvement	Cystoscopy with biopsy and urine cytology	CT, MRI pelvis
Rectal infiltration	Proctoscopy with biopsy	CT, MRI pelvis; barium enema
Hydronephrosis	IVP	Renal ultrasonography; CT abdomen
Pulmonary metastases	Chest radiography	CT chest; PET scan
Retroperitoneal lymphadenopathy	—	lymphangiogram, CT, MRI, PET scan

CT, Computed tomography; *FIGO,* Federation of International Gynecologists and Obstetricians; *HIV,* human immunodeficiency virus; *IVP,* intravenous pyelography; *MRI,* magnetic resonance imaging; *OCP,* oral contraceptive pill; *PET,* positron emission tomography; *STD,* sexually transmitted disease.
From Disaia PJ et al: *Clinical gynecologic oncology*, ed 9, Philadelphia, 2017, Elsevier.

TABLE 4 Federation of International Obstetrics and Gynecology Staging of Cervical Cancer

Stage	Invasion	Prognosis 5-Year Survival	Treatment
I_{A1}	Depth of invasion ≤3 mm and width ≤7 mm (includes early stromal invasion of up to 1 mm)	98%-99%	Local excision; if margins of a LLETZ/cone clear (i.e., no residual tumor or CIN) then conization is adequate, with no need for pelvic lymphadenectomy.
I_{A2}	Depth of invasion 3.1-5 mm and width ≤7 mm	95%	Simple hysterectomy and pelvic lymphadenectomy. If fertility sparing required, large cone and lymphadenectomy
I_{B1}	Tumor confined to cervix and diameter <4 cm	90%-95%	Radical hysterectomy (and lymphadenectomy)
I_{B2}	Tumor confined to cervix and diameter >4 cm	80%	Chemo–radiotherapy
II_A	Upper two-thirds of vagina	70%-90%	Chemotherapy & radiotherapy
II_B	Upper two-thirds of vagina plus parametrial disease	60%-70%	Chemo–radiotherapy
III_A	Lower third of vagina	30%-50%	Chemotherapy & radiotherapy
III_B	Pelvic sidewall and/or hydronephrosis		Chemo–radiotherapy
IV_A	Bladder, rectum	20%	Chemo–radiotherapy
IV_B	Beyond pelvis		

CIN, Cervical intraepithelial neoplasi; *LLETZ,* large loop excision of the transformation zone.
From Magowan BA: *Clinical obstetrics and gynecology,* ed 4, 2019, Elsevier.

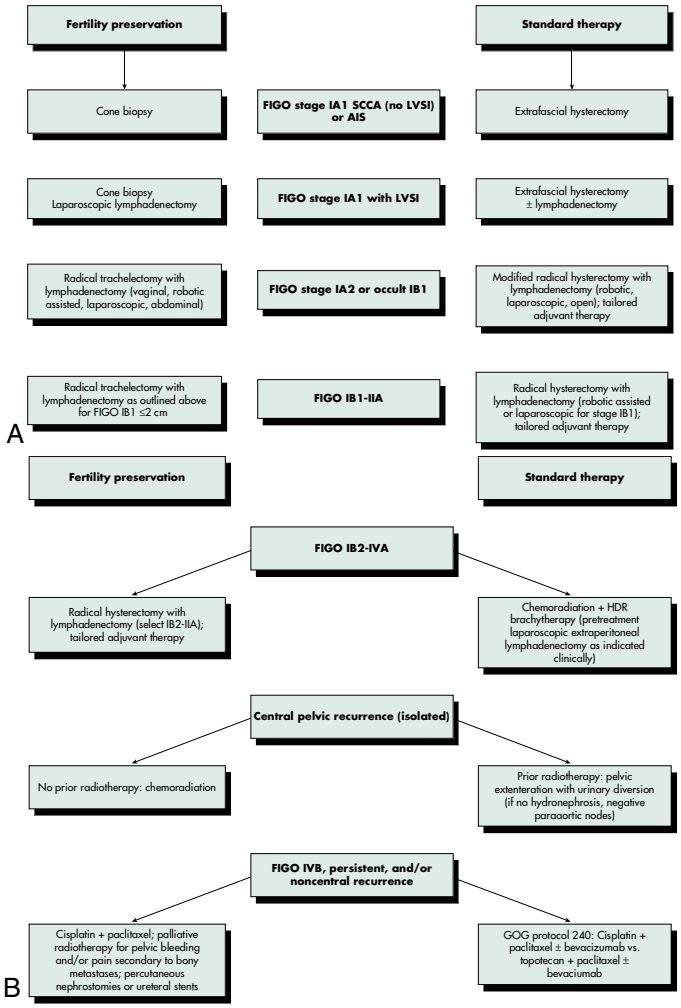

FIG. 4 A and **B,** Algorithm for therapy. *AIS,* Adenocarcinoma *in situ; FIGO,* Federation of International Gynecologists and Obstetricians; *GOG,* gynecologic oncology group; *HDR,* high-dose rate; *LVSI,* lymphovascular space invasion, *SCCA,* squamous cell carcinoma associated antigen. (From Disaia PJ et al: *Clinical gynecologic oncology*, ed 9, Philadelphia, 2017, Elsevier.)

TABLE 5 Proposed Schedule for Interval Evaluation of Cervical Cancer after Radiotherapy or Surgery (Asymptomatic Patient*)

Year	Frequency	Examination
1	3 mo	Pelvic examination, Pap smear
	6 mo	Chest radiography, CBC, BUN, creatinine
	1 yr	IVP or CT scan with contrast
2	4 mo	Pelvic examination, Pap smear
	1 yr	Chest radiography, CBC, BUN, creatinine, IVP or CT scan with contrast
3-5	6 mo	Pelvic examination, Pap smear

BUN, Blood urea nitrogen; *CBC,* complete blood count; *CT,* computed tomography; *IVP,* intravenous pyelogram; *Pap,* Papanicolaou.
*Symptomatic patients should have appropriate examination where indicated.
From Disaia PJ et al: *Clinical gynecologic oncology*, ed 9, Philadelphia, 2017, Elsevier.

TABLE 6 American Cancer Society Guidelines for Screening by Cytology for the Early Detection of Cervical Neoplasia and Cancer

- No screening is recommended regardless of sexual initiation or other risk factors before the age of 21.
- Women between the ages of 21 and 29 yr should have a Pap test every 3 yr. They should not be tested for human papillomavirus (HPV) unless such testing is needed after an abnormal Pap test result.
- Women between the ages of 30 and 65 yr should have both a Pap test and an HPV test every 5 yr. This is the preferred approach, but it is also acceptable to have a Pap test alone every 3 yr.
- Women older than 65 yr who have had regular screenings with normal results should not be screened for cervical cancer. Women who have been diagnosed with cervical precancer should continue to be screened.
- Women who have had their uterus and cervix removed in a hysterectomy and have no history of cervical cancer or precancer should not be screened.
- Women who have had the HPV vaccine should still follow the screening recommendations for their age group.
- Women who are at high risk for cervical cancer may need to be screened more often. Women who are at high risk might include those with human immunodeficiency virus (HIV) infection, organ transplantation, or exposure to the drug diethylstilbestrol (DES). They should talk with a doctor or nurse.

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

2. After age 30, women can be screened with cytology and HPV testing every 5 yr.
3. Before age 21, women should not be screened unless HIV positive. If HIV positive, they should begin screening within 1 yr of coitarche.
4. Before age 30, women should not be screened with HPV testing.

- At age 65, screening can stop in women with three consecutive negative cytology results or two consecutive negative cytology results combined with a negative HPV test within the last 10 yr (with the most recent test within 5 yr).
- Women without a cervix should not be screened.

Cervical Disc Syndromes (PTG)

BASIC INFORMATION

DEFINITION

Cervical disc syndromes result from disc herniation and degenerative changes in the cervical spine. The symptoms can be categorized as cervical radiculopathy (nerve root impingement) if the stenosis is most significant at the neural foramen, or as myelopathy (spinal cord impingement) if the stenosis is more central in the spinal canal. Central cord stenosis (myelopathy) can result in both upper- and lower-extremity symptoms, while foraminal narrowing typically results in radicular symptoms (Fig. E1).

SYNONYMS

Cervical myelopathy
Cervical radiculopathy
Cervical spondylopathy (degenerative vs. traumatic)

ICD-10CM CODES

M50.00	Cervical disc disorder with myelopathy, unspecified cervical region
M50.01	Cervical disc disorder with myelopathy, high cervical region
M50.02	Cervical disc disorder with myelopathy, mid-cervical region
M50.03	Cervical disc disorder with myelopathy, cervicothoracic region
M50.10	Cervical disc disorder with radiculopathy, unspecified cervical region
M50.11	Cervical disc disorder with radiculopathy, high cervical region
M50.12	Cervical disc disorder with radiculopathy, mid-cervical region
M50.13	Cervical disc disorder with radiculopathy, cervicothoracic region
M50.20	Other cervical disc displacement, unspecified cervical region
M50.21	Other cervical disc displacement, high cervical region
M50.22	Other cervical disc displacement, mid-cervical region
M50.23	Other cervical disc displacement, cervicothoracic region
M50.30	Other cervical disc degeneration, unspecified cervical region
M50.31	Other cervical disc degeneration, high cervical region
M50.32	Other cervical disc degeneration, mid-cervical region
M50.33	Other cervical disc degeneration, cervicothoracic region
M50.80	Other cervical disc disorders, unspecified cervical region
M50.81	Other cervical disc disorders, high cervical region
M50.82	Other cervical disc disorders, mid-cervical region
M50.83	Other cervical disc disorders, cervicothoracic region
M50.90	Cervical disc disorder, unspecified, unspecified cervical region
M50.91	Cervical disc disorder, unspecified, high cervical region
M50.92	Cervical disc disorder, unspecified, mid-cervical region
M50.93	Cervical disc disorder, unspecified, cervicothoracic region

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence of cervical radiculopathy can be up to 107.3 and 64.5 per 100,000 men and women, respectively, in the U.S.
PREVALENCE: Up to 67% of all adults experience neck and arm pain at some point in their life.
PREDOMINANT SEX AND AGE: Males and females are affected equally between the ages of 30 and 60. Most commonly, cervical myelopathy is seen in patients >55 yr of age.
RISK FACTORS: Risk factors include aging, repetitive microtrauma to the neck, and, potentially, genetic factors, although research is ongoing.
GENETICS: No definitive genetic associations have been identified, though family history likely plays a role.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Neck pain, especially with extension, and limited neck range of motion. Spurling sign (pain on axial compression of the neck while it is extended and the head is turned to the affected side) is usually positive in the setting of foraminal stenosis.
- Referred unilateral interscapular pain.
- Numbness, tingling, or radiating pain in a dermatomal distribution may be secondary to nerve root impingement at the associated level (radicular symptoms).
- Extremity or hand weakness and clumsiness, gait disturbance and spasticity in upper and lower extremities (myelopathic symptoms), abnormal reflexes: Positive Hoffman sign, positive inverted radial reflex, and hyperactive biceps and triceps reflexes are usually seen in myelopathic patients.

ETIOLOGY

Degeneration of vertebral bodies, intervertebral disc herniations, hypertrophy of facets, uncovertebral joints, and ligamentum flavum can all lead to spinal cord and/or nerve root impingement causing cervical disc syndrome.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Muscle spasms
- Rotator cuff tendinitis/tear
- Frozen shoulder
- Carpal tunnel syndrome
- Cubital tunnel syndrome
- Radial tunnel syndrome
- Thoracic outlet syndrome
- Brachial neuritis or brachial plexopathy
- Cervical spine epidural abscess
- Malignancy (primary or metastatic) causing nerve root or spinal cord impingement

A differential diagnosis for evaluation of neck pain is described in Section II.

WORKUP

Combination of clinical diagnosis and radiologic studies (x-ray and MRI).

LABORATORY TESTS

No specific labs are required; however, CBC and inflammatory markers (erythrocyte sedimentation rate/c-reactive protein) can be obtained if infectious cause or inflammatory conditions are suspected.

IMAGING STUDIES

- Plain radiographs (Fig. E2) should be obtained first to rule out traumatic causes (fracture, subluxation, dislocation, spondylolisthesis).
  1. Usually normal in soft disc herniation or foraminal stenosis, but loss of disk height between vertebral bodies may indicate disease.
  2. With chronic degenerative disc disease, loss of disc height, anterior and posterior osteophyte formation, and encroachment on the intervertebral foramen by osteophytes may be seen.
- CT myelography or MRI (Fig. E3) is indicated in patients with neurologic symptoms that do not resolve with conservative management or when other spinal pathology is suspected.
- Electrodiagnostic studies can be used to confirm the diagnosis or rule out peripheral nerve disorders.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Rest and soft or hard cervical collar can be used to immobilize the neck for brief periods of time.
- Local modalities such as heat and ice may help.
- Physical therapy.
- Avoid extreme range-of-motion exercises in degenerative disc disease, although some find relief with traction.

ACUTE GENERAL Rx

- Nonsteroidal antiinflammatory drugs or oral steroids
- Muscle relaxants
- Analgesics as needed
- Epidural steroid injection for radicular pain

CHRONIC Rx

- If acute modalities and nonoperative therapies fail, patients can be evaluated for surgical intervention.
- Nerve ablation for chronic pain in patients who may not be safe for surgery.
- Discectomy or decompression and/or fusion for symptomatic cervical discs.

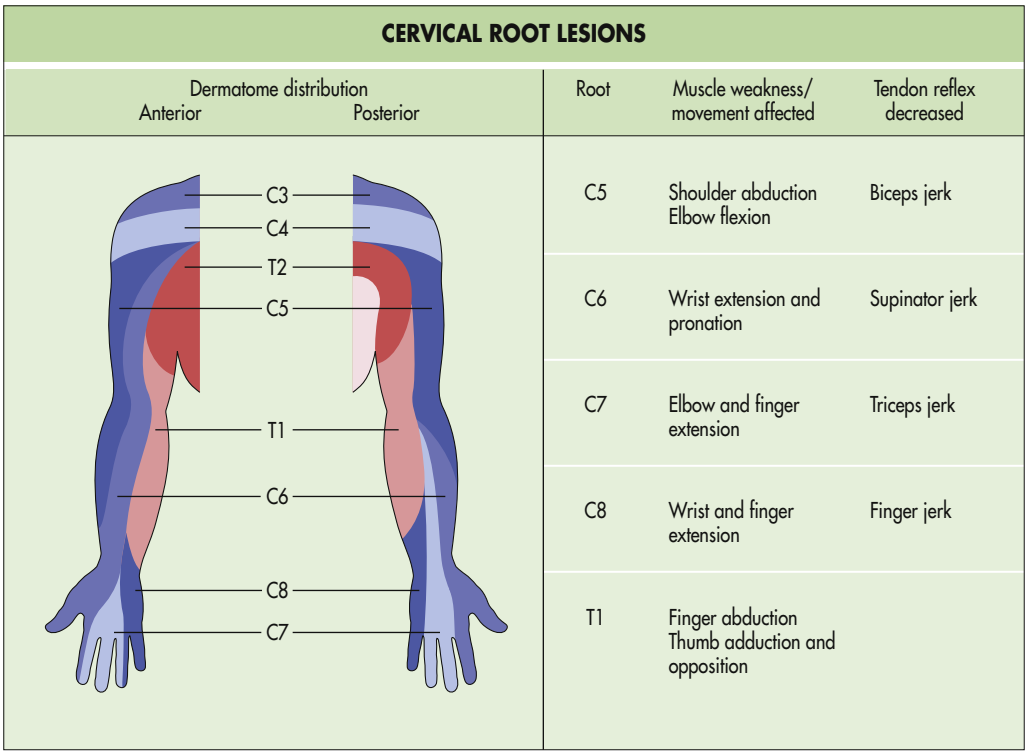

FIG. E1 Sensory and motor distribution of the cervical roots. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

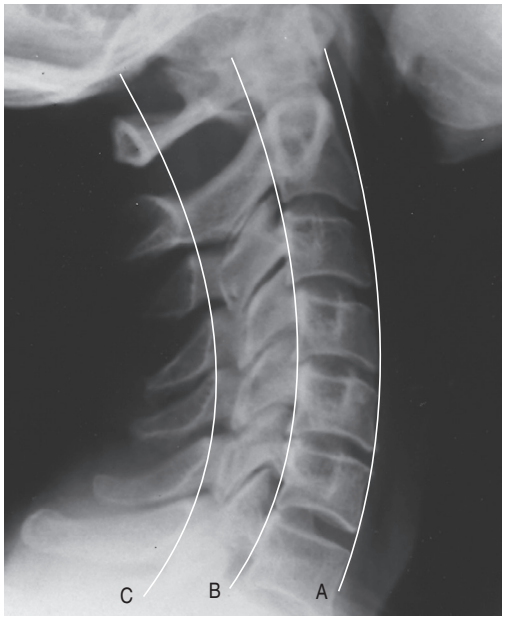

FIG. E2 Plain lateral radiograph of a normal cervical spine. Lines joining the anterior part of the vertebral body **(A)**, the posterior aspect of the vertebral body **(B)**, and the anterior border of the laminae **(C)** should describe a smooth arc. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Herbal antiinflammatory medications
- Chiropractic care
- Acupuncture
- Deep-tissue massage

DISPOSITION

- Acute radiculopathy usually improves with time.
- Myelopathy is a stepwise decline with progressive symptoms.
- Surgical intervention is normally offered to approximately 5% of the patients.

REFERRAL

Orthopedic or neurosurgical consultation for intractable pain or worsening neurologic deficit

PEARLS & CONSIDERATIONS

Myelopathy from cervical spondylosis is the most common cause of acquired spastic paralysis in the adult and is usually progressive. Decisions about surgical intervention are complicated in these patients.

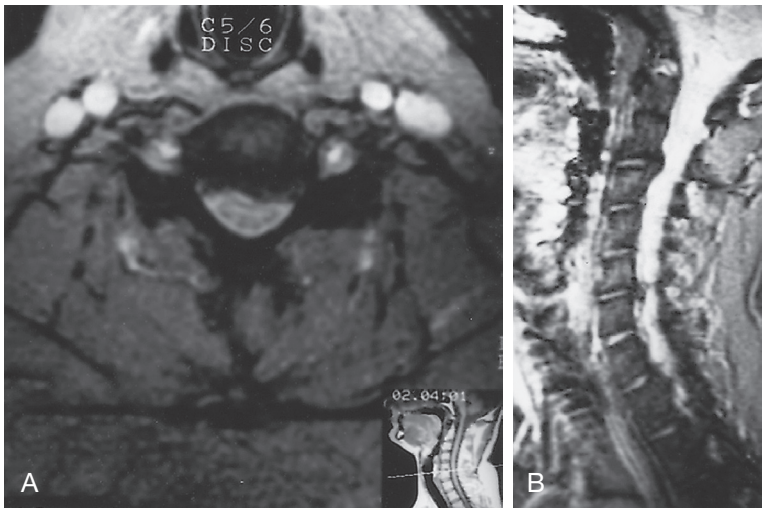

FIG. E3 Disk herniation on magnetic resonance imaging (MRI). Axial **(A)** and sagittal **(B)** MRI scans of a 47-yr-old man with neck pain, decreased left biceps jerk, and numbness over his thumb after a motor vehicle accident demonstrate a significant left posterolateral disk protrusion at C5 to C6 that is significantly compromising the exiting C6 nerve root. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

COMMENTS

- Pain relief with physical therapy is variable; any overall improvement usually parallels what would have likely occurred naturally.
- Sometimes carpal tunnel syndrome and cervical radiculopathy occur together; this is termed *double-crush syndrome,* pointing to the fact that the nerve is being compressed at two separate levels. Proximal compression may decrease the ability of the nerve to tolerate a second, more distal compression.
- Surgical intervention is indicated primarily for relief of radicular pain caused by nerve root compression or for the treatment of progressive myelopathy; it is generally not helpful when the chief complaint is neck pain alone without extremity symptoms.
- In many cases of cervical spondylosis with myelopathy, the lower extremity symptoms are much more disabling than the neck symptoms.

PREVENTION

No known prevention exists.

BASIC INFORMATION

DEFINITION

Cervical dysplasia refers to atypical development of immature squamous epithelium that does not penetrate the basement epithelial membrane and is caused by persistent infection with human papillomavirus (HPV). Characteristics include increased cellularity, nuclear abnormalities, and increased nuclear/cytoplasmic ratio. A progressive loss of squamous differentiation exists beginning adjacent to the basement membrane and progressing to the most advanced stage (severe dysplasia), which encompasses the complete squamous epithelial layer thickness. The revised 2001 Bethesda System terminology was used in a National Institutes of Health consensus conference, sponsored by the American Society for Colposcopy and Cervical Pathology (ASCCP) and its partner professional organizations in 2006. The conference updated therapeutic options for women based on studies such as the **A**SC-US (atypical squamous cells of undetermined significance)/**L**SIL (low-grade squamous intraepithelial lesions) **T**riage **S**tudy (ALTS) that appeared after revision of the Bethesda classification. Fig. 1 provides a comparison of grading systems for cervical squamous dysplasia.

In 2012, the American Cancer Society (ACS), ASCCP, and American Society for Clinical Pathology (ASCP) published a new set of recommendations for lifetime assessment and early diagnosis of cervical dysplasia and cancer. The recommendations attempted to reduce the number of lifetime assessments, thereby reducing the possible morbidity associated with excess testing and also optimizing the co-evaluation with Pap smear and HPV testing.

UPDATED SCREENING PROTOCOL:

- Women younger than 21 yr of age should not have cervical cancer screening unless HIV positive. If HIV positive, screening should start within 1 yr of coitarche.
- Women 21 to 29 yr of age should have testing every 3 yr with only cytology. With negative cytology or HPV-negative ASC-US, patients can repeat every 3 yr. For HPV-positive ASC-US or cytology with LG-SIL, follow-up is as per the 2006 guidelines, typically a colposcopic examination as the initial step with follow-up steps depending on the findings.
- Women between the ages of 30 and 65 yr should have co-testing every 5 yr with both Pap cytology and HPV testing. Alternatively, it is also acceptable to perform cytology alone, but then the testing interval should be every 3 yr. With negative cytology or HPV-negative ASC-US, patients can repeat with co-testing every 5 yr. For HPV-positive ASC-US or cytology with LG-SIL, follow-up is as per the 2006 guidelines, as previously documented. For patients with positive HPV but negative cytology, the patient can repeat testing 12 months later with co-testing. Patients can also specifically test for HPV 16 or HPV 16/18 genotypes and, if positive, should be referred for colposcopy. Patients with positive HPV but negative 16 and/or 18 should be retested in 12 months with co-testing.
- Women older than the age of 65 and those with a history of hysterectomy (including removal of cervix) should no longer be tested unless they had previous diagnosis of cervical intraepithelial neoplasia (CIN) 2 or more severe; these women should be tested for at least 20 yr. Women who have been vaccinated for HPV should still use age-specific recommendations for screening.

BETHESDA 2001 UPDATED CLASSIFICATION: The Bethesda 2001 System was the result of a year-long iterative process held to update the original 1991 system and to broaden participation in the consensus process, clarify reporting of abnormalities, and incorporate data that had been collected since the initial system was created.

The reporting system includes the following areas:

- *Specimen adequacy:* The system defines the specimen as either satisfactory for evaluation or unsatisfactory and then specifies the reason for inadequacy if necessary.
- *General categorization (optional):* This serves to triage the specimen into normal finding (negative for intraepithelial lesion or malignancy) or identifies it as an "epithelial abnormality." The descriptions are meant to be mutually exclusive.
- *Interpretation/result:* Makes a distinction between "interpretation" and "diagnosis" of the specimen so that the interpretation may be incorporated into the overall clinical context for the particular patient being evaluated.
- *Negative for intraepithelial lesion or malignancy:* In this screening test, no intraepithelial lesion or malignancy is identified. Non-neoplastic findings such as organisms or reactive cellular findings may be specified but are still considered to be a negative result.
- Epithelial cell abnormalities:
  1. Squamous cell:
     a. Atypical squamous cell (ASC) of undetermined significance (ASC-US) emphasizing the unusual but still possible association with underlying CIN II/III and extremely rare possibility of squamous cell carcinoma.
     b. ASC cannot exclude high-grade squamous intraepithelial lesion (HSIL) (ASC-H), suggesting a risk for CIN II/III that is intermediate between ASC-US and HSIL.
     c. LSIL suggests a transient viral infection with a greater likelihood for regression, more likely to encompass HPV infection and CIN I histologically.
     d. HSIL suggestive of a more persistent viral infection and with a greater risk for progressive disease, more likely to encompass CIN II/III and carcinoma in situ (CIS) histologically.
     e. Squamous cell carcinoma.
  2. Glandular cell:
     a. Atypical glandular cells (should specify endocervical, endometrial, or not otherwise specified).
     b. Atypical glandular cell, favor neoplasia (should specify endocervical or not otherwise specified).

Histological features	Traditional system	WHO system	British Society for Cervical Cytology	Bethesda system
Atypical squamous cells not meeting the criteria for dysplasia	Mild atypia	Mild atypia	Borderline nuclear abnormality	Atypical squamous cells (ASC)
Koilocytes plus mild atypia	HPV infection	HPV infection	HPV plus borderline change	Low-grade squamous intraepithelial lesion (SIL)
Dysplasia limited to lower third of epithelium	Mild dysplasia	CIN 1	Mild dyskaryosis (low-grade dyskaryosis)	Low-grade SIL
Dysplasia limited to lower two-thirds of epithelium	Moderate dysplasia	CIN 2	Moderate dyskaryosis (high-grade dyskaryosis)	High-grade SIL
Dysplasia extending into upper third of epithelium	Severe dysplasia	CIN 3	Severe dyskaryosis (high-grade dyskaryosis)	High-grade SIL
Dysplasia of full thickness of epithelium	Carcinoma in situ	CIN 3	Severe dyskaryosis (high-grade dyskaryosis)	High-grade SIL

FIG. 1 Comparison of grading systems. *CIN,* Cervical intraepithelial neoplasia; *HPV,* human papillomavirus; *WHO,* World Health Organization. (From Young B et al: Female reproductive system. In *Wheater's basic pathology,* Philadelphia, 2011, Elsevier, pp. 216-315.)

c. Endocervical adenocarcinoma in situ (AIS).
d. Adenocarcinoma.

3. Other: Endometrial cells in a woman ≥40 yr of age. Because menopausal status is sometimes uncertain, age was chosen to discriminate women who might, with the findings of endometrial cells on cytology, warrant further evaluation with endometrial sampling.

KEY POINTS:

- The cytologic distinctions of low grade (LSIL) and high grade (HSIL) do not necessarily equate to the histologic classifications CIN I and CIN II/III.
- The 2006 conference noted that one cytologic abnormality can have different histologic risk in different women and highlights "special populations" such as adolescent and young women, and those women who are pregnant. In young women, spontaneous HPV clearance rates are exceptionally high. The testing recommendations essentially removed the possibility of testing women younger than 21 yr of age.
- DNA testing for high-risk HPV types is incorporated into the evaluation and treatment algorithms for women with cytologic cervical abnormalities.

Histologically, a two-tiered system is developed in this guideline that distinguishes between the lower-risk CIN I and higher-risk CIN II/III diagnoses.

ICD-10CM CODES

N87.9	Dysplasia of cervix uteri, unspecified
R87.610	Atypical squamous cells of undetermined significance on cytologic smear of cervix (ASC-US)
R87.611	Atypical squamous cells cannot exclude high grade squamous intraepithelial lesion on cytologic smear of cervix (ASC-H)
R87.612	Low grade squamous intraepithelial lesion on cytologic smear of cervix (LGSIL)
R87.613	High grade squamous intraepithelial lesion on cytologic smear of cervix (HGSIL)
R87.614	Cytologic evidence of malignancy on smear of cervix
R87.615	Unsatisfactory cytologic smear of cervix
R87.618	Other abnormal cytological findings on specimens from cervix uteri
R87.619	Unspecified abnormal cytological findings in specimens from cervix uteri
Z12.4	Encounter for screening for malignant neoplasm of cervix

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT AGE:

- Dysplasia: Peak age, 26 yr (3600 cases/100,000 persons)
- CIS: Peak age, 32 yr (1100 cases/100,000 persons)
- Invasive cancer: Peak age <60 yr (800 cases/100,000 persons)

PEAK INCIDENCE:

- Age 35
- Abnormal Pap smear rate revealing dysplasia approximates 2% to 5% depending on population risk factors and false-negative rate variance
- False-negative rate approaching 40%
- Average age-adjusted incidence of severe dysplasia is 35 cases/100,000 persons
- Approximately half of the cases of new cervical cancer had never been screened, and another 10% had not been screened in more than 5 yr. Many of these women come from underserved or underresourced communities. The single biggest impact in reducing the morbidity and mortality from cervical cancer would come from appropriately addressing these health disparities.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cervical lesions associated with dysplasia often are not visible to the naked eye; therefore, physical findings are best viewed by colposcopy of a 3% acetic acid-prepared cervix or Lugol solution
- Patients evaluated by colposcopy are identified by abnormal cervical cytology screening from Pap smear screening
- Colposcopic findings:
  1. Leukoplakia (white lesion seen by the unaided eye that may represent condyloma, dysplasia, or cancer)
  2. Acetowhite epithelium with or without associated punctation, mosaicism, abnormal vessels
  3. Abnormal transformation zone (abnormal iodine uptake, "cuffed" gland openings)
- Studies have looked at the benefit of taking random biopsies at time of colposcopy and have shown that there may be increased detection of CIN II or greater if biopsies are taken at random rather than only directed toward abnormal appearing lesions

ETIOLOGY

- Strongly associated and initiated by oncogenic HPV infection (high-risk HPV types are 16, 18, 31, 33, 35, 45, 51, 52, 56, and 58; low-risk HPV types are 6, 11, 42, 43, and 44)
- Risk factors:
  1. HPV
  2. Any heterosexual coitus
  3. Coitus during puberty (transformation-zone metaplasia peak)
  4. Diethylstilbestrol exposure
  5. Multiple sexual partners
  6. Lack of prior Pap smear screening
  7. History of STD
  8. Other genital tract neoplasia
  9. HIV
  10. Tuberculosis
  11. Substance abuse
  12. "High-risk" male partner (HPV)
  13. Low socioeconomic status
  14. Early first pregnancy
  15. Tobacco use

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metaplasia
- Hyperkeratosis
- Condyloma
- Microinvasive carcinoma
- Glandular epithelial abnormalities
- Vulvar intraepithelial neoplasm
- Vaginal intraepithelial neoplasm
- Metastatic tumor involvement of the cervix

WORKUP

- Periodic history and physical examination (including cytologic screening) depending on age, risk factors, and history of preinvasive cervical lesions
- Consider screening for sexually transmitted disease (gonorrhea, *Chlamydia,* herpes, HIV, HPV)
- Abnormal cytology (HSIL/LSIL, initial ASC/ASC-US/ASC-H in high-risk patients, recurrent in low-risk/postmenopausal patients) and grossly evident suspicious lesions; refer for colposcopy and possible directed biopsy/endocervical curettage (ECC; examination should include cervix, vagina, vulva, and anus)
- For glandular cell abnormalities (AGCs): Refer for colposcopy and possible directed biopsy/ECC, and consider endometrial sampling
- In pregnancy: Abnormal cytology followed by colposcopy in the first trimester and at 28 to 32 wk; only high-grade lesions suspicious for carcinoma biopsied; ECC is contraindicated

LABORATORY TESTS

- Gonorrhea, chlamydia nucleic-acid amplification tests to rule out STD
- Pap cytology screening (requires appropriate sampling, preparation, cytologist interpretation, and reporting)
- Colposcopy and directed biopsy, ECC for indications (see "Workup")
- HPV DNA typing if identified abnormal cytology
- As compared with Pap testing, HPV testing has greater sensitivity for the detection of intraepithelial neoplasia

IMAGING STUDIES

- Cervicography
- Computer-enhanced Pap cytology screening (e.g., PAPNET)

MANAGEMENT

Refer to the literature for a more comprehensive approach. The following treatment paradigms in Table 1 give a general outline for care.

DISPOSITION

- Because of the large number of women in high-risk groups, the prevalence of HPV, and the high false-negative Pap smear rate, routine Pap smear screening should be strongly encouraged for all women, especially those with a history of cervical dysplasia. The

TABLE 1 Summary of Recommendations

Population	Recommended Screening Method	Management of Screen Results	Comments
<21 yr	No screening		
21-29 yr	Cytology alone every 3 yr	HPV-positive ASC-US or cytology of LSIL or more severe: Refer to ASCCP Guidelines Cytology Negative or HPV-Negative ASC-US; Rescreen with cytology in 3 yr	
30-65 yr	HPV and cytology "cotesting" every 5 yr (preferred)	HPV-positive ASC-US or cytology of LSIL or more severe: Refer to ASCCP guidelines	Screening by HPV testing alone is not recommended for most clinical settings.
		HPV positive, cytology negative: Option 1: Y 12-month follow-up with co-testing	
		Option 2: Y test for HPV16 or HPV16/18 genotypes. If HPV16 or HPV16/18 positive, refer to colposcopy. If HPV16 or HPV16/18 negative, 12-mo follow-up with cotesting	
		Co-test negative or HPV-negative ASC-US: Rescreen with cotesting in 5 yr	
	Cytology alone every 3 yr (acceptable)	HPV-positive ASC-US or cytology of LSIL or more severe: Refer to ASCCP guidelines	
		Cytology negative or HPV-negative ASC-US: Rescreen with cytology in 3 yr	
>65 yr	No screening following adequate negative prior screening		Women with a history of CIN2 or a more severe diagnosis should continue routine screening for at least 20 yr
After hysterectomy	No screening		Applies to women without a cervix and without a history of CIN2 or a more severe diagnosis in the past 20 yr or cervical cancer ever.
HPV vaccinated	Follow age-specific recommendations (same as unvaccinated women)		

ASCCP, American Society for Colposcopy and Cervical Pathology; *ASC-US,* atypical squamous cells of undetermined significance; *CIN,* cervical intraepithelial neoplasia; *HPV,* human papillomavirus; *LSIL,* low-grade squamous intraepithelial lesions.

Modified from Saslow D et al: American Cancer Society, American Society for Colposcopy and Cervical Pathology, and American Society for Clinical Pathology screening guidelines for the prevention and early detection of cervical cancer, *J Low Gen Tract Dis* 16(3):175-204, 2012.

addition of an HPV test to the Pap test reduces the incidence of CIN II or III, or cancer detected by subsequent screening.
- Success rates for treatment approach 80% to 90%.
- Detection of persistence of recurrence requires careful follow-up.
- Cervical treatment possibly results in infertility (cervical stenosis or incompetence), which requires careful consideration and discretion for use of loop electrosurgical excision procedure and cone biopsy.
- Appropriate counseling and informed consent are needed when considering any form of management of cervical dysplasia.

REFERRAL

- Patients with abnormal Pap cytology should be referred to a provider, preferably a trained obstetrician/gynecologist, who can appropriately treat the patient in an age-specific manner and also perform a colposcopy if indicated as part of the new recommendations. Given the morbidity associated with both underevaluating and treating, as well as reacting excessively to cytologic findings, a provider who is intimately familiar with ASCCP guidelines should be sought.
- If treatment is required, patient should be referred to a gynecologist or gynecologic oncologist skilled in the diagnosis and treatment of preinvasive cervical disease.

PEARLS & CONSIDERATIONS

COMMENTS

- Testing for human papillomavirus by Hybrid capture 2 DNA test will identify 91% of the small proportion of women with post-treatment residual or recurrent disease, but 30% of all women who are tested will test positive and need colposcopy.
- HPV vaccination is recommended for males and females from ages 9 to 26.

BASIC INFORMATION

DEFINITION

Gradual, painless dilation of the cervix during pregnancy, leading to recurrent inability to maintain pregnancy beyond the second trimester. Cervical dilation occurs in the absence of clinical contractions and/or labor. Diagnosis is clinical.

SYNONYMS

Incompetent cervix
Shortened cervix
Preterm birth syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1 in 1000 among general obstetrical population
RISK FACTORS: Prior cervical surgery (e.g., cone biopsy, loop electrosurgical excision procedure [LEEP]), in utero diethylstilbestrol (DES) exposure, prior first- or second-trimester abortions, uterine anomalies, multiple gestations, prior spontaneous preterm births not meeting the criteria for cervical insufficiency

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Painless cervical dilation during the second trimester
- Nonspecific presentation: Backache, pelvic pressure, contractions, vaginal spotting, vaginal discharge

ETIOLOGY

Most cases are either idiopathic or iatrogenic as a result of prior cervical surgery. The cause is thought to be a loss of elastic fibers in the cervices of affected women.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Preterm labor
- Shortened cervix

WORKUP

- Prior obstetrical history, particularly with regard to previous preterm deliveries or spontaneous abortions
- Prior history of any gynecological procedures, especially those involving the cervix
- Serial digital cervical exams
- Serial transvaginal ultrasound

LABORATORY TESTS

Amniocentesis with analysis for white blood cell count, glucose, Gram stain, and culture: Abnormal results for any of these markers may indicate a subclinical infection, which increases risk for preterm birth. Abnormalities may help in selecting patients who would benefit from emergent cerclage, although this benefit should be weighed against the inherent risks of amniocentesis.

IMAGING STUDIES

Transvaginal ultrasound: Cervical shortening on ultrasound may be a diagnostic marker for cervical insufficiency.

TREATMENT

NONPHARMACOLOGIC THERAPY

Cerclage has long been the mainstay of treatment for cervical insufficiency (Fig E1 to E3). However, randomized controlled trials (RCTs) comparing the rates of preterm birth in patients receiving cervical cerclage versus those without cerclage have produced conflicting results, with many studies showing little or no improvement in preterm birth rates. A meta-analysis by Berghella et al (2005) showed that the greatest benefit of cerclage was in women with singleton pregnancies who had experienced a previous preterm birth, and cerclage was actually detrimental to women carrying multiple gestations. The most common risk associated with cerclage is cervical laceration during delivery (1% to 13%). Bed rest is often used when there is a threat of preterm birth, although its benefit is not proven and it has detrimental effects for the mother, such as venous thromboembolic events; thus it is not recommended.

ACUTE GENERAL Rx

Ultrasound-indicated cerclage should be placed in women with ultrasonographic evidence of cervical shortening (<25 mm) before 24 weeks' gestation and a history of a preterm birth before 34 weeks. Women who present with painless cervical dilation in the second trimester may be candidates for a physical-exam–indicated cerclage (rescue cerclage) after being ruled out for uterine activity and evidence of infection. Data are limited on the efficacy of placing a physical-exam–indicated cerclage. Women should be counseled about the potential risks of rescue cerclage in the setting of unclear benefit. Placement of a cervical pessary is only currently recommended in the setting of research trial protocols.

CHRONIC Rx

Prophylactic cerclage (history-indicated cerclage) has been shown by several studies and meta-analyses to be most heavily indicated in women with prior history of multiple preterm births. Women with a history of one or more

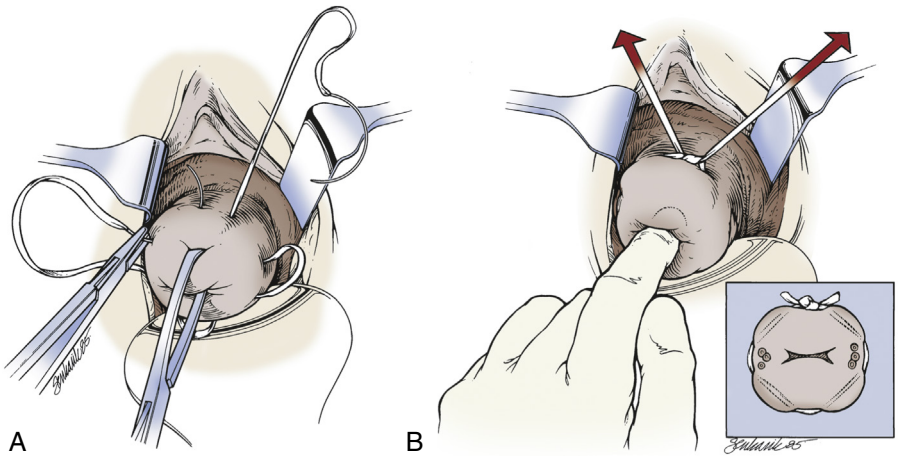

FIG. E1 Placement of sutures for McDonald cerclage. A, We use a double-headed Mersilene band with four bites in the cervix, avoiding the vessels. **B,** The suture is placed high up in the cervix, close to the cervicovaginal junction, approximately at the level of the internal os. (From Gabbe SG: *Obstetrics*, ed 6, Philadelphia, 2012, Saunders.)

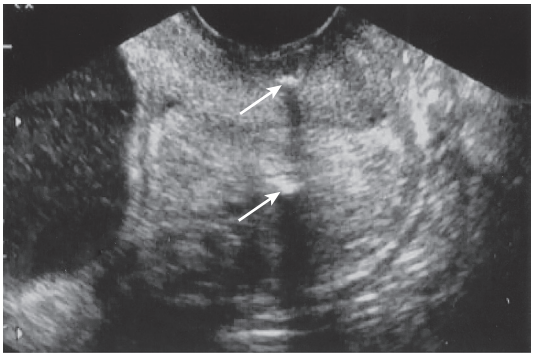

FIG. E2 Transvaginal sonogram of the cervix after cerclage placement. The internal os is closed, and there is no funneling. Echogenic spots in the cervix correspond to cerclage *(arrows).* (From Gabbe SG: *Obstetrics*, ed 6, Philadelphia, 2012, Saunders.)

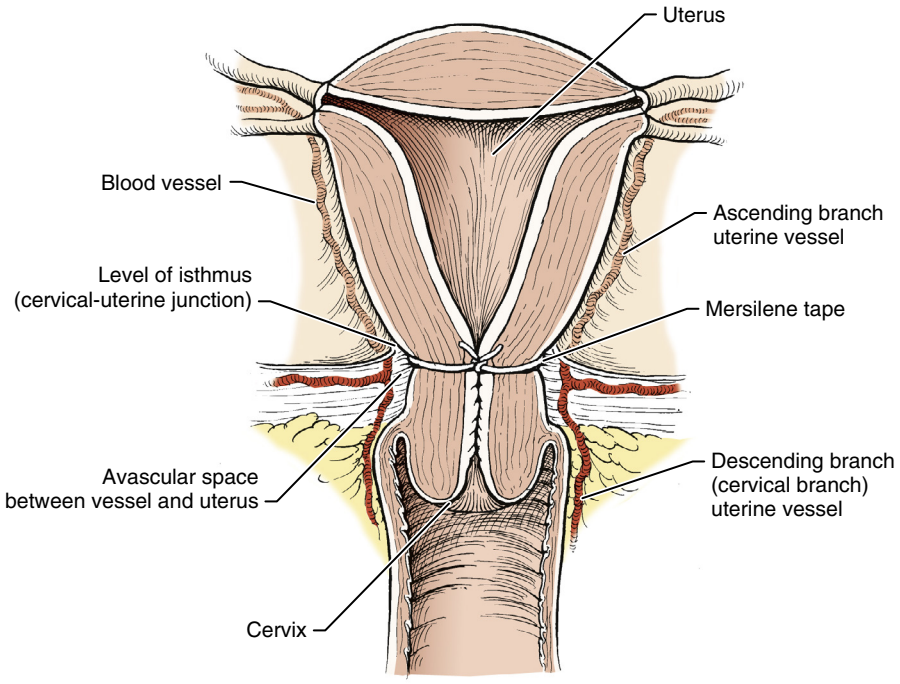

FIG. E3 Abdominal cerclage. Surgical placement of circumferential Mersilene tape around uterine isthmus and median to uterine vessels. Knot is tied anteriorly. (From Gabbe SG: *Obstetrics*, ed 6, Philadelphia, 2012, Saunders.)

second-trimester deliveries with no symptoms or signs of labor at the time of the delivery may be candidates for a prophylactic cerclage, placed at 13 to 14 weeks' gestation. Women with this history should also be offered 17-OH progesterone injections between 16 and 36 weeks.

DISPOSITION

Patients with a singleton pregnancy, prior history of preterm birth, and shortened cervix (<25 mm) on transvaginal ultrasound should be counseled regarding amniocentesis and cerclage placement.

REFERRAL

Patients at risk of preterm labor should be referred to maternal-fetal medicine.

Cervical Polyps (PTG)

BASIC INFORMATION

DEFINITION

A cervical polyp is a growth or tumor protruding from the cervix or endocervical canal. These can arise from the ectocervix or endocervix.

ICD-10CM CODES

N84.1	Polyp of cervix uteri
D26.0	Polyp uterine cervix, adenomatous

EPIDEMIOLOGY & DEMOGRAPHICS

Cervical polyps are found in approximately 4% of all gynecologic patients. They most commonly present in perimenopausal and multigravida women between the ages of 30 and 50. Ectocervical polyps are more common in postmenopausal women, whereas endocervical polyps are most common in premenopausal women. Endocervical polyps are more common overall than ectocervical polyps and are almost always benign. Malignant degeneration is extremely rare (1%).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Polyps may be single or multiple and vary in size from being extremely small (a few mm) to large (4 cm). They are soft, smooth, and reddish-purple to cherry-red in color. They bleed easily when touched. Very large polyps can cause some cervical dilation. There may be vaginal discharge and bleeding associated with cervical polyps, especially if the polyp has become infected.

ETIOLOGY

- Most unknown
- Inflammatory
- Traumatic
- Pregnancy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Endometrial polyp
- Prolapsed myoma
- Retained products of conception
- Squamous papilloma
- Sarcoma
- Cervical malignancy

WORKUP

Polyps are most commonly asymptomatic and are usually found at the time of annual gynecologic pelvic examination. Polyps are also found in women who present for evaluation of abnormal uterine bleeding (intermenstrual or postcoital bleeding) and for profuse vaginal discharge. Polyps are generally painless. Unless a patient had a bleeding abnormality that necessitated evaluation by a physician, polyps would go undiagnosed until the next speculum examination or Pap smear was obtained.

TREATMENT

NONPHARMACOLOGIC THERAPY

Asymptomatic polyps do not require treatment. If a patient is symptomatic, simple surgical excision can be done in the office. Most commonly, a polyp is excised by grasping it at the stalk with a sponge forceps or similar device and twisting it off. The provider should be prepared for bleeding post removal, which can be controlled with silver nitrate or Monsel solution application. Polyps can also be excised by electrocautery. Sexual intercourse and tampon use are to be avoided until the patient's follow-up visit. Although cervical polyps are overwhelmingly benign, they should be sent to pathology for definitive histologic diagnosis.

ACUTE GENERAL Rx

Generally, cervical polyps do not present acutely and no medication is needed.

CHRONIC Rx

The cervix should be examined at the patient's routine office gynecologic visits before and after removal of a polyp. Patients should be screened for polyp symptoms, including abnormal vaginal discharge and bleeding at routine appointments.

DISPOSITION

Because these polyps are almost always benign, no further treatment is usually needed. Annual gynecologic examinations should be performed to check for any evidence of regrowth of the polyp.

REFERRAL

To a gynecologist for removal of polyps

PEARLS & CONSIDERATIONS

COMMENTS

A Pap smear should be obtained before removing the polyp. If an abnormal Pap smear is obtained, it is possible that the cause was the polyp. If the pathology report on the polyp reveals any histologic or cytologic abnormality, further evaluation with colposcopy, endocervical sampling, or endometrial biopsy may be necessary. If a cervical colposcopic evaluation is needed, this should also be performed.

During pregnancy the cervix is highly vascularized. If the polyps are stable and benign appearing, they should be observed during the pregnancy and removed only if they cause heavy bleeding.

AUTHORS: **T. Caroline Bank, MD,** and **Rachel Wright Heinle, MD, FACOG**

Cervicitis PTG

BASIC INFORMATION

DEFINITION

Cervicitis is an inflammation of the uterine cervix, primarily affecting the columnar epithelial cells of the endocervical glands. Acute cervicitis results from direct infection of the cervix secondary to a uterine or vaginal infection—most commonly chlamydia or gonorrhea—whereas chronic cervicitis is due to an exposure to a local irritant.

SYNONYMS

Endocervicitis
Ectocervicitis
Mucopurulent cervicitis

ICD-10CM CODES

N72	Inflammatory disease of cervix uteri
A54.03	Gonococcal cervicitis, unspecified
A74.89	Other chlamydial diseases
A60.03	Herpesviral cervicitis
O86.11	Cervicitis following delivery

EPIDEMIOLOGY & DEMOGRAPHICS

The published prevalence of cervicitis varies greatly, ranging from 8% to as high as 40% of women attending sexually transmitted disease (STD) clinics. Cervicitis is most common in women aged 15 to 24 but it can occur in any sexually active woman. Women who have had sex without condoms or sex with multiple partners are at increased risk of developing cervicitis as well as other STDs.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Cervicitis is usually asymptomatic or associated with mild symptoms. Patients may complain of copious purulent or mucopurulent vaginal discharge, pelvic pain, postcoital or intermenstrual bleeding, vulvovaginal irritation, or dyspareunia.

The CDC emphasizes that the two diagnostic signs of cervicitis are either mucopurulent discharge or sustained cervical bleeding with gentle trauma. On physical exam, the cervix can be erythematous and tender on palpation. The cervix may also bleed easily when obtaining cultures or a Pap smear. Yellow discharge will be seen on a Q-tip inserted into the cervix.

INFECTIOUS ETIOLOGY

- *Chlamydia trachomatis*
- *Neisseria gonorrhoeae*
- *Trichomonas vaginalis*
- Herpes simplex
- Human papillomavirus
- *M. genitalium*
- Bacterial vaginosis

DIAGNOSIS

The diagnosis of acute cervicitis is clinical and based upon the presence of purulent or mucopurulent cervical exudate and/or cervical friability—bleeding induced by gently touching the area with a swab.

DIFFERENTIAL DIAGNOSIS

- Carcinoma of the cervix
- Cervical erosion (from tampons or other intravaginal devices)
- Cervical metaplasia
- Cervical ectropion
- Cervical and vaginal irritation due to chemicals or hormonal imbalance

WORKUP

If cervicitis is suspected, testing for infectious causes should be performed and pelvic inflammatory disease (PID) should be excluded.

LABORATORY TESTS

- A finding of leucorrhea (>10 WBC per high-power field on microscopic examination of vaginal fluid) has been associated with chlamydial and gonococcal infection of the cervix.
- Nucleic acid amplification tests (NAAT) should be used for diagnosing *C. trachomatis* and *N. gonorrhoeae* in women with cervicitis; this testing can be performed on vaginal, cervical, or urinary samples.
- Use a wet mount to look for evidence of bacterial vaginitis (BV) and trichomonads, but because the sensitivity of microscopy to detect *T. vaginalis* is relatively low (~50%), symptomatic women with cervicitis and negative microscopy for BV and trichomonads should receive further testing with NAAT or culture if there is concern for resistant infection.
- HIV testing is recommended in all patients with supposed cervicitis.
- Although HSV-2 infection has been associated with cervicitis, the utility of specific testing (i.e., culture or serologic testing) for HSV-2 in this setting is not recommended unless there are clinical findings suggestive of herpes infection.

TREATMENT

NONPHARMACOLOGIC THERAPY

- The patient's history of hygiene habits, which may increase her risk for cervicitis, should be obtained including history of douching, tampon usage, and other potential chemical exposures to vaginal irritants.
- Uncomplicated cervicitis is typically treated as an outpatient.
- Safe sex should be recommended including monogamous relationships and the consistent use of condoms (male and female).
- Sexual partners should be offered treatment in all cases of STD infection proven by culture.

ACUTE GENERAL Rx

Because *Chlamydia* and *N. gonorrhoeae* cause 50% of cases of infectious cervicitis, if either of these infections is suspected, then treatment should be initiated without waiting for the test results. Administer ceftriaxone 250 mg IM single dose followed by azithromycin 1 g single dose or doxycycline 100 mg PO bid for 7 days. If the patient is pregnant, treat with azithromycin 1 g single dose instead of using doxycycline, which is contraindicated in pregnant or nursing mothers. If *Trichomonas* is the etiologic agent, treat with metronidazole or tinidazole 2 g single dose, which is curative in 95% of cases. An alternative treatment option is metronidazole 500 mg twice daily for 7 days. Alcohol should be avoided during the treatment course.

For herpes infection, treat with acyclovir, valacyclovir, or famciclovir.

M. genitalium might be considered for cases of clinically significant cervicitis that persist after azithromycin or doxycycline therapy in which reexposure to an infected partner or medical nonadherence is unlikely. If *M. genitalium* infection is confirmed, treatment is with moxifloxacin.

DISPOSITION

Bacterial cervicitis responds well to antibiotics. Possible complications to watch for include subsequent PID and infertility (found in 5% to 10% of patients with increasing rates with repeat episodes of PID). Repeat cervical cultures are recommended after treatment in pregnancy or if there is concern of treatment failure. Screening for reinfection is recommended within 3 months. Condoms should be recommended and sexual relations should be resumed after negative cultures for both partners.

REFERRAL

If subsequent PID develops, attempt outpatient therapy and consider hospital admission for IV antibiotics for severe or specialty cases as outlined in the CDC guidelines.

PEARLS & CONSIDERATIONS

COMMENTS

- Management of sex partners of women tested for cervicitis should be appropriate for the identified or suspected STD.
- Repeat testing 3 to 6 months after treatment is recommended for all women diagnosed with chlamydia or gonorrhea, and all sex partners in the preceding 60 days should be evaluated and treated for the STDs for which the index patient received treatment.

Chagas Disease

BASIC INFORMATION

DEFINITION

Chagas disease is an infection caused by the protozoan parasite *Trypanosoma cruzi.* This is a vector-borne disease transmitted by reduviid bugs from multiple wild and domesticated animal reservoirs. The disease is characterized by an acute nonspecific febrile illness that may be followed, after a variable latency period, by chronic cardiac, GI, and neurologic sequelae. Globally, Chagas disease affects 8 to 11 million persons; vector-borne disease (as opposed to congenital infection) occurs only in the Americas.

SYNONYM

American trypanosomiasis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Seven cases of autochthonous transmission in California, Texas, Tennessee, and Louisiana.
- In the past two decades, six cases of laboratory-acquired infection, three cases of transfusion-associated transmission, and nine cases of imported disease reported to the CDC (none of the imported cases involved returning tourists).
- Infection has been transmitted by organ transplantation.
- Infection has been transmitted congenitally from mother to fetus over more than one generation.
- Stercorarian transmission (i.e., transmission through the feces of an infected vector) is relatively inefficient; the incidence of *T. cruzi* infection is generally estimated to be less than 1% per yr. The highest incidence is 4% per yr in the hyperendemic Bolivian Chaco (Bern C in Suggested Readings: *NJEM* 373:456-466, 2015).

PREVALENCE (IN U.S.): Based on regional seroprevalence studies in Hispanic blood donors, it is estimated that between 300,000 and 300,500 persons infected with *T. cruzi* are currently residing in the U.S. In the Americas, 8 to 10 million people are believed to be infected.

PREDOMINANT SEX: Male = female

PREDOMINANT AGE:

- In highly endemic areas, mean age of acute infection: Approximately 4 yr.
- Variable age distribution for both types of chronic disease, depending on geography.
- Mean age of onset of chronic disease: Usually between 35 and 45 yr.

PEAK INCIDENCE: Unknown

GENETICS:

- **Congenital infection:** Congenital transmission is common, with attendant high fetal mortality and morbidity in surviving infants.
- **Neonatal infection:** In rural areas, within substandard housing, transmission is likely to occur.

PHYSICAL FINDINGS & CLINICAL PRESENTATIONS

- Inflammatory lesion that develops about 1 wk after contamination of a break in the skin with infected insect feces (chagoma)
  1. Area of induration and erythema
  2. Usually accompanied by local lymphadenopathy
  3. This lesion may be easily overlooked and ignored
- Presence of Romaña sign, which consists of unilateral painless palpebral and periocular edema (Fig. E1), when conjunctiva is portal of entry. This is rare but almost pathognomonic.
- Constitutional symptoms of fever, fatigue, and anorexia, along with edema of the face and lower extremities, generalized lymphadenopathy, and mild hepatosplenomegaly after the appearance of local signs of disease
- Myocarditis in a small portion of patients, sometimes with resultant CHF, even death.
- Uncommonly, CNS disease, such as meningoencephalitis, which carries a poor prognosis
- Symptoms and signs of disease persisting for weeks to months followed by spontaneous resolution of the acute illness; patient then enters the indeterminate phase of the disease (asymptomatic with attendant subpatent parasitemia and reactive antibodies to *T. cruzi* antigens)
- Chronic disease may become manifest yrs to decades after the initial infection:
  1. Most common organ involved: Heart followed by GI tract; GI tract disease occurs most commonly in the Southern Cone of South America, due to variations in strains of *T. cruzi* resulting in different tropisms. Cardiac involvement predominates in all areas of infection. Cardiac involvement takes the form of arrhythmias or cardiomyopathy but rarely both
  2. Cardiomyopathy is bilateral but predominantly affects the right ventricle and is often accompanied by apical aneurysms and mural thrombi
  3. Arrhythmias are a consequence of involvement of the bundle of His and have been implicated as the leading cause of sudden death in adults in highly endemic areas
  4. Right-sided heart failure, thromboembolism, and rhythm disturbances associated with symptoms of dizziness and syncope are characteristic
  5. Myocardial fibrosis can serve as a nidus for ventricular tachycardia; can be excised surgically after EP mapping
     a. Patients with megaesophagus: Dysphagia, odynophagia, chronic cough, and regurgitation, frequently resulting in aspiration pneumonitis
     b. Megacolon: Abdominal pain and chronic constipation, which, when severe, may lead to obstruction and perforation
     c. CNS symptoms: Most often secondary to embolization from the heart
     d. Varying degrees of peripheral neuropathy

ETIOLOGY

- *T. cruzi:*
  1. Found only in the Americas, ranging from the southern U.S. to northern Argentina (Fig. E2)
  2. Transmitted to humans by various species of bloodsucking reduviid ("kissing") insects (Fig. E3), primarily those of the genera *Triatoma, Panstrongylus,* and *Rhodnius*
  3. Usually found in burrows and trees where infected insects transmit the parasite to natural reservoirs (e.g., opossums and armadillos)
  4. Intrusion into enzootic areas for farmland, allowing insects to take up residence in rural dwellings, thus including humans and domestic animals in the cycle of transmission
  5. Initial infection of insects by ingesting blood from animals or humans that have circulating flagellated trypanosomes (trypomastigotes)
  6. Multiplication in the insect midgut as epimastigotes, then differentiation into metacyclic trypomastigotes discharged with the feces during subsequent blood meals
  7. Transmission to the second mammalian host through contamination of mucous mem-

FIG. E1 Romaña sign in an Argentinean child with acute Chagas disease. (Courtesy Dr. Humberto Lugones, Santiago del Estero, Argentina.)

branes, conjunctivae, or wounds with insect feces containing infectious forms (Fig. E4)

- In the vertebrate host:
  1. Movement of parasites into various cell types, intracellular transformation into amastigotes, and thereafter differentiation into trypomastigotes
  2. Following rupture of the cell membrane, parasitic invasion of local tissues or hematogenous spread to distant sites, maintaining a parasitemia infective for vectors
- In addition to insect vectors, *T. cruzi* is transmitted through blood transfusions, transplacentally, and, occasionally, secondary to laboratory accidents or ingestion (including breast milk)
- Infection by the oral route causes more severe acute infection, even death
- In 2007, voluntary screening was initiated in the U.S. blood supply; it is estimated to cover 75% to 90% of the blood supply
- Platelet transfusions appear to be more infective than packed red blood cells

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute disease:
- Early African trypanosomiasis
- New World cutaneous and mucocutaneous leishmaniasis

Chronic disease:
- Idiopathic cardiomyopathy
- Idiopathic achalasia
- Congenital or acquired megacolon

WORKUP

Principal considerations in diagnosis:
- A history of residence where transmission is known to occur
- Recent receipt of a blood product while in an endemic area
- Occupational exposure in a laboratory
- Children of infected mothers
- Siblings/family members of infected individuals

LABORATORY TESTS

For acute diagnosis:
- Demonstration of *T. cruzi* in wet preparations of blood (Fig. E5), buffy coat, or Giemsa-stained smears.
- Xenodiagnosis, a technique involving laboratory-reared insect vectors fed on subjects with suspected infection thereafter examined for parasites, and culture of body fluids in liquid media to establish diagnosis.
  1. Hampered by the length of time required for completion
  2. Of limited use in clinical decision making with regard to drug therapy
  3. Although xenodiagnosis and broth culture are considered to be more sensitive than microscopic examination of body fluids, sensitivities may not exceed 50%
  4. This test is rarely used
- Recent advances in serologic testing include immunoblot assay, in situ indirect fluorescent antibody, PCR-based techniques, and an immunochromatographic assay (Chagas Stat Pak).
- Response to treatment in acute, reactivated, or congenital infection can be assessed by quantitative PCR. This test is now standardized and in common use.

For chronic *T. cruzi* infection:
- Traditional serologic tests, including complement fixation (CF), indirect immunofluorescence (IIF), indirect hemagglutination, and enzyme-linked immunosorbent assay (ELISA).
- Serologic tests have variable sensitivity and specificity and frequent false-positive results.
- Saliva ELISA may be useful as a screening diagnostic test in epidemiologic studies of chronic trypanosomiasis infection in endemic areas.
- Confirmation requires at least two different tests, and if discordant, three tests.

FIG. E2 Distribution of Chagas disease. Human infection is endemic in parts of Central and South America from the Andes to the Atlantic coast and as far south as the latitude of the Silver River (Río de la Plata, shown in *green*). Two major intergovernmental programs were started in 1991 to eliminate domestic vectors by a combination of spraying residual insecticides in houses, the use of insecticidal paints, and the deployment of fumigant canisters. The countries covered in the two initiatives, the second of which started in 1997, are shown. The latter program instituted universal blood screening to avoid transmission from infected blood donors. In less than a decade, remarkable progress has been made. Transmission by the major vector *Triatoma infestans* was eliminated in Uruguay by 1997 and in Chile by 1999. Major reductions in transmission have also been reported from other endemic countries but, to date, not complete control. (From Hoffman R: *Hematology, basic principles and practice*, ed 6, Philadelphia, 2013, Elsevier.)

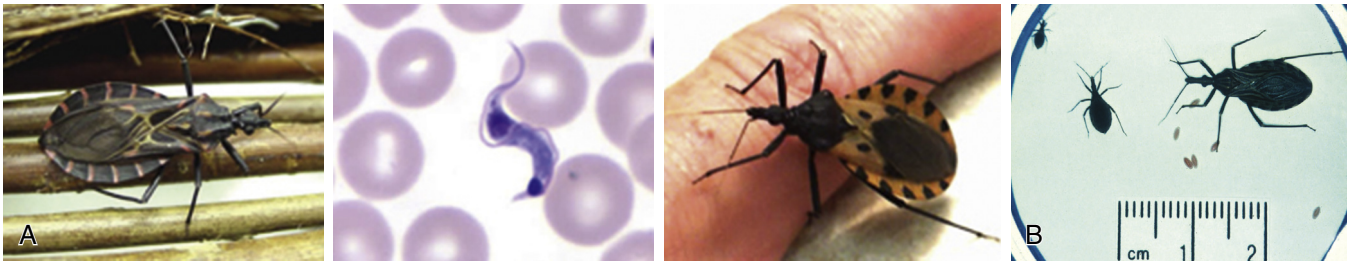

FIG. E3 Triatomine vectors of Trypanosoma cruzi. A, Triatoma infestans. **B,** Rhodnius prolixus. (**A**, Courtesy Centers for Disease Control and Prevention, Atlanta GA. **B**, From Kirchhoff LV: *Trypanosoma* species [American trypanosomiasis, Chagas' disease]: biology of trypanosomes. In (Bennett JE, Dolin R, Blaser MJ [eds]: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

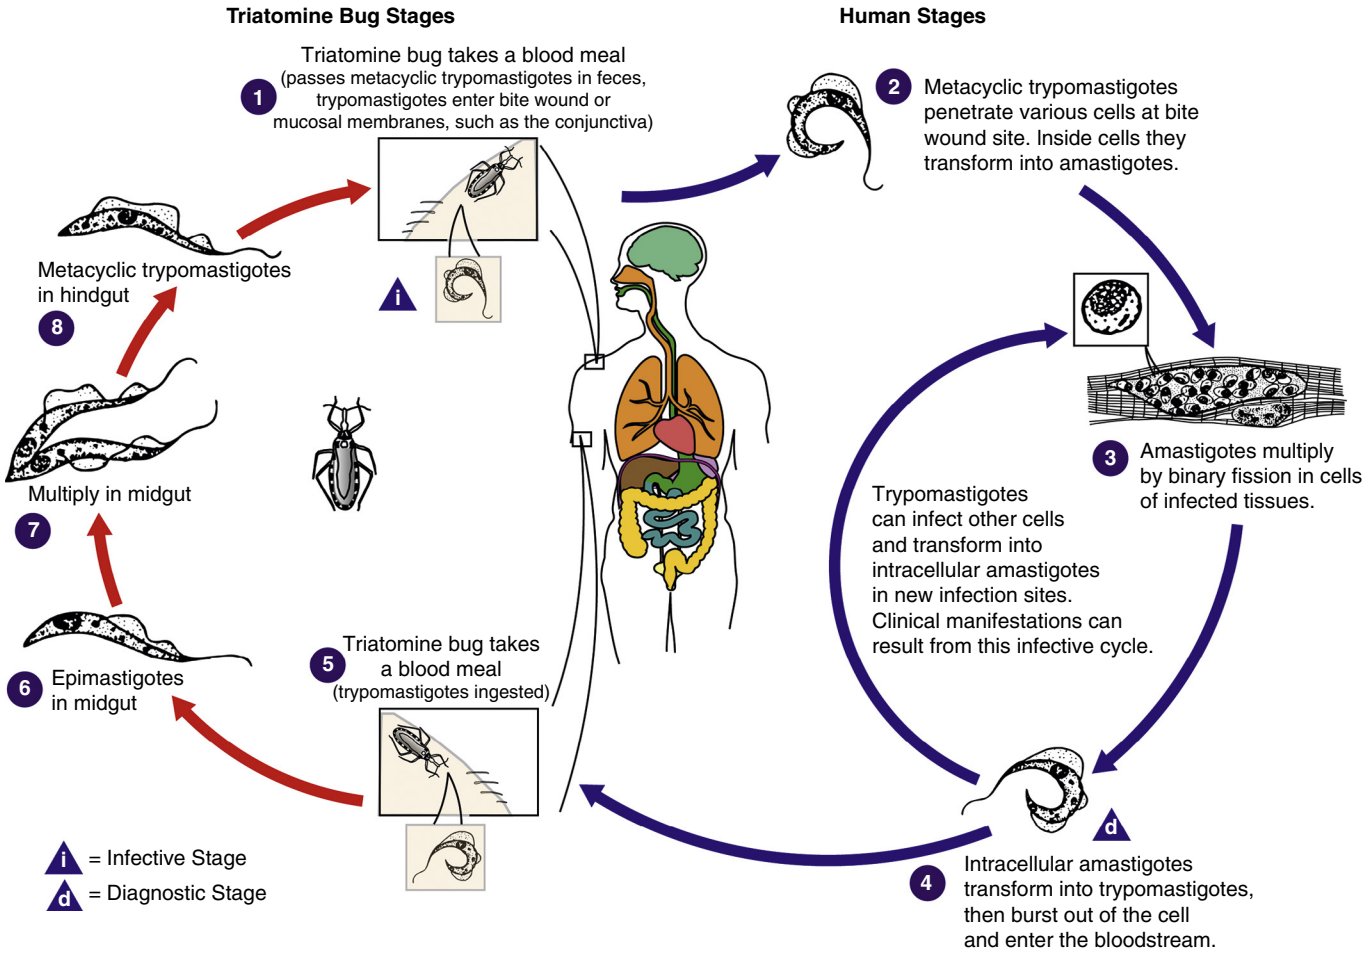

FIG. E4 Life cycle of *Trypanosoma cruzi* in its insect vectors and mammalian hosts. (Courtesy Centers for Disease Control and Prevention, Atlanta, GA.)

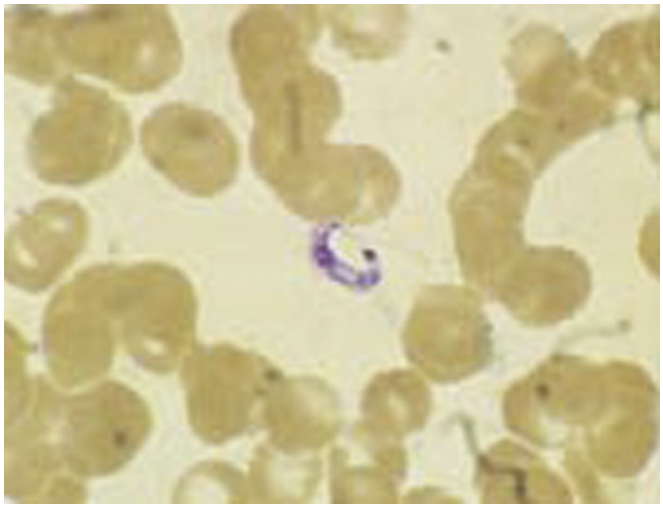

FIG. E5 *Trypanosoma cruzi* in human blood film. The causative agent occurs in blood films, characteristically as short C-shaped or S-shaped trypomastigotes with a prominent kinetoplast. It is otherwise monomorphic. (From Hoffman R et al.: *Hematology, principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Chronic chagasic heart disease: Mainly supportive including ICD, pacers, amiodarone, heart transplant.
- Megaesophagus: Symptoms usually amenable to dietary measures or pneumonic dilation of the esophagogastric junction
- Chagasic megacolon: In its early stages, responsive to a high-fiber diet, laxatives, and enemas

ACUTE GENERAL Rx

It is now recommended that all patients—acute, indeterminate, and chronic—be treated with antiparasitic therapy. Treatment for individuals older than 50 yr requires consideration of risk versus benefit because the treatment appears to be more toxic at this age. Patients with severe chronic cardiomyopathy also may not benefit. Severity of illness scores specific to Chagas disease have been developed to assess this.

A single course of benznidazole or nifurtimox is thought to offer an approximately 50% cure rate. Consultations and requests for drugs can be made to Parasitic Diseases Public Inquiries Line (770-448-7775), parasites.cdc.gov, www.cdc.gov/parasites/chagas, CDC Drug Service (404-639-3670).

Benznidazole, a nitroimidazole derivative:
- Has demonstrated similar efficacy as nifurtimox in limited trials; is usually better tolerated and is viewed by most experts as first-line treatment
- Recommended oral dosage: 5 to 7 mg/kg/day for 30 to 90 days

Nifurtimox:
- Recommended oral dosage for adults: 8 to 10 mg/kg/day given in 3 to 4 divided daily doses and continued for 90 to 120 days
- Parasitologic cure in approximately 50% of those treated; should be begun as early as possible

Neither drug can be used during pregnancy.
- Do not use in cases of severe renal or hepatic dysfunction.

Triazoles offer a new class of therapy but are so far disappointing. Case reports have had success with posaconazole. Trials have shown that posaconazole has antitrypanosomal activity in patients with chronic Chagas disease. However, significantly more patients in the posaconazole groups than in the benznidazole group had treatment failure during follow-up.

CHRONIC Rx

- Yearly cardiac evaluations and 12 lead ECG should be performed in all persons with *T. cruzi* infection regardless of treatment.
- In patients with indeterminate phase or chronic disease: Some evidence of benefit in a recent uncontrolled trial with benznidazole in patients with chagasic cardiomyopathy
- In patients exhibiting bradyarrhythmias: Pacemakers
- In individuals with congestive heart failure:
  1. Treat with standard modalities for dilated, right-sided cardiomyopathic disease
  2. Cardiac transplant is an option for end-stage cardiomyopathy; moreover, reactivation rate found to be low and amenable to therapy without subsequent infection of the allograft
  3. Myotomy or esophageal resection is reserved for patients with advanced disease
  4. Anticoagulation for patients at risk for thromboembolism
  5. Antiarrhythmic for complex arrhythmias
- In advanced chagasic megacolon associated with chronic fecal impaction, perforation, or, less commonly, volvulus: Surgical resection

DISPOSITION

Based on a few prospective studies, although most patients infected with *T. cruzi* will not develop symptomatic Chagas disease, 20% to 30% likely will.

REFERRAL

- For consultation with an infectious disease specialist for all patients
- Communication with the CDC when the disease is acutely suspected
- To a cardiologist for pacemaker implantation for patients with bradyarrhythmias and for management of CHF, complex arrhythmias
- To a surgeon for symptomatic disease with chagasic megaesophagus or megacolon

PEARLS & CONSIDERATIONS

COMMENTS

- All children of an infected mother should be screened for Chagas disease; household members should also be screened.
- In recipients of solid organ or bone marrow transplants, patients with AIDS, or those receiving chemotherapy, there may be reactivation of indeterminate phase disease.
- Mortality predictors associated with chagasic cardiomyopathy include CHF, QT-interval dispersion, left ventricular end-systolic dimension, the presence of pathologic Q waves, frequent PVCs, and isolated LAFB on ECG.
- Chagasic esophageal disease has an increased incidence of esophageal malignancy.
- The use of pyrethroid-impregnated curtains may represent an option for the reduction or elimination of Chagas disease transmission in certain endemic areas.
- Randomized trials of benznidazole for chronic Chagas cardiomyopathy have shown significant serum parasite detection but no significant reduction in clinical deterioration through 5 yr of follow-up (Morillo CA et al in Suggested Readings: *NEJM* 373:1295-1306, 2015).

Chalazion

BASIC INFORMATION

DEFINITION

Chalazia (singular, chalazion singular) are the most common inflammatory lesions of the eyelid, accounting for approximately 13% of all benign eyelid lesions. These lesions typically present as localized areas of painless swelling and feel like a rubbery nodule to palpation. Chalazia are caused by obstruction of Zeis or meibomian glands when lipid breakdown by-products incite localized inflammatory response, which then recruits white blood cells to the area. This results in a sterile, painless lesion, which grows over weeks to months. Can eventually become infected and painful if not treated.

SYNONYMS

Meibomian gland lipogranuloma
Sebaceous cyst
Meibomian cyst

ICD-10CM CODES

H00.1	Chalazion
H00.11	Right upper eyelid
H00.12	Right lower eyelid
H00.13	Right eye, unspecified eyelid
H00.14	Left upper eyelid
H00.15	Left lower eyelid
H00.16	Left eye, unspecified eyelid
H00.19	Unspecified eye, unspecified eyelid

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Common condition, exact incidence not documented
PEAK INCIDENCE: Most common in adults age 30 to 50
PREVALENCE: Unknown
PREDOMINANT SEX AND AGE: Affects males and females equally, more common in adults 30 to 50 yr old
GENETICS: Not applicable

RISK FACTORS:

- Prior chalazion, recent conjunctivitis
- Consider demodicidosis in patients with recurrent chalazia
- Consider low serum vitamin A

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Painless localized nodule on the eyelid (Fig. E1)
- Lesion will be firm and rubbery. Can see mild erythema
- Possible impaired vision
- Increased swelling for weeks/months
- Can become inflamed/painful/infected
- Can be visualized on the external eyelid or internal eyelid
- Tend to present for longer than 2 weeks compared to styes, which usually have a shorter course
- Typically, benign and self-limited lesion. If persistent or recurrent, a chalazion should be evaluated for malignancy

ETIOLOGY

Chalazia appear as small, red, rubbery nodules that are caused by local inflammation and obstruction of the sebaceous glands of the eyelids. Obstruction of the sebaceous glands results in lipid buildup and stasis. The lipid breakdown by-products incite localized inflammation, which then recruits white blood cells to the area.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Blepharitis
- Hordeolum (stye)
- Papilloma
- Xanthelasma
- Carcinoma: Sebaceous cell, basal cell, squamous cell (biopsy necessary)
- Dacryocystitis
- Molluscum contagiosum
- Leishmaniasis
- Periorbital/orbital cellulitis
- Abscess

Recurrent or persistent lesions:

- Basal cell carcinoma
- Sebaceous cell carcinoma
- Meibomian gland carcinoma

WORKUP

Diagnosis is based on symptoms, clinical presentation, and physical exam findings. Testing is largely used to rule out other diagnoses. If suspicious for cancer, biopsy is necessary as well as ophthalmologic consultation.

LABORATORY TESTS

None necessary for chalazion. Other diagnoses might indicate laboratory analysis

IMAGING STUDIES

None

TREATMENT

- Frequently resolve without intervention
- Warm compress 15 minutes 2 to 4×/day
- Massage affected area with warm soap and water
- Incision and drainage if infection persists
- Ophthalmologic consultation if persistent beyond 1 month
- Antibiotics if pain/infected
  1. Doxycycline 100 mg PO bid 10 days
  2. Minocycline 50 mg PO 10 days
  3. Metronidazole if tetracycline allergic

DISPOSITION

Excellent patient prognosis. Small chalazia can be discharged home with instructions for conservative management. Large, recurrent, or persistent lesions may require an ophthalmology referral.

REFERRAL

If not resolved in 1 month ophthalmologic consultation is warranted

PEARLS & CONSIDERATIONS

COMMENTS

Frequently chalazia are confused with stye. Chalazia are inflammatory lesions, not infectious, that usually develop slowly in the upper eyelid and tend to be painless. Styes are infected oil glands that tend to present at the lid margin with pain.

PREVENTION

No specific prevention other than normal facial washing and hygiene.

BASIC INFORMATION

DEFINITION

Chancroid is a sexually transmitted disease characterized by painful genital ulceration and inflammatory inguinal adenopathy.

SYNONYMS

Soft chancre
Ulcus molle

ICD-10CM CODE
A57 Chancroid

EPIDEMIOLOGY & DEMOGRAPHICS

- Most frequent cause of genital ulcer disease worldwide.
- Endemic in the developing world.
- Exact incidence in is unknown. The prevalence of chancroid has declined in the United States and is currently rare (1 per 2 million in the developed world).
- Often due to infection with *Haemophilus ducreyi,* affecting microabrasions in skin.
- When infection occurs, it is usually associated with sporadic outbreaks and in association with trading sex for drugs or money.
- Predominantly heterosexual transmission.
- Occurs more frequently in men (male:female ratio of 5:1 to 10:1).
- There is a higher incidence in uncircumcised men and in tropical and subtropical regions.
- Incubation period is 4 to 7 days but may take up to 3 wk.
- High incidence of HIV infection associated with chancroid.
- Chancroid may facilitate the transmission of HIV.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Genital papule that evolves into soft ulcer with necrotic material at base and minimal surrounding inflammation.
- One to three extremely painful ulcers (Fig. E1) measuring 1 to 2 cm in diameter followed by tender inguinal lymphadenopathy (especially if fluctuant). The chancre is typically soft in comparison with the hard, painless chancre of syphilis.
- May present with inguinal bubo and several ulcers.
- In women: Initial lesion in the fourchette, labia minora, urethra, cervix, or anus; inflammatory pustule or papule that ruptures, leaving a shallow, nonindurated ulceration, usually 1 to 2 cm in diameter with ragged, undermined edges.
- Unilateral lymphadenopathy develops 1 wk later in 50% of patients.

ETIOLOGY

Haemophilus ducreyi, a gram-negative bacillus

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other genitoulcerative diseases such as syphilis, herpes, lymphogranuloma venereum (LGV), granuloma inguinale.
- A clinical algorithm for the initial management of genital ulcer disease is described in Section III.

WORKUP

Diagnosis based on history and physical examination is often inadequate. Must rule out syphilis and herpes simplex virus in women because of the consequences of inappropriate therapy in those who are pregnant and due to potentially similar presentation. Practitioner can base initial diagnosis and treatment recommendations on clinical impression of appearance of ulcer and most likely diagnosis for population. Definitive diagnosis is made by isolation of organism from ulcers by culture or Gram stain. Special culture media for *H. ducreyi* is not widely available commercially, and even when these media are used, sensitivity is <80%. PCR and NAAT are not cost-effective and are complex tests.

The CDC criteria for probable clinical diagnosis include all of the following:

- Single or multiple painful genital ulcers
- No evidence to support a diagnosis of syphilis (no evidence of *T. pallidum* infection by darkfield examination or ulcer exudate or by a serologic test for syphilis performed at least 7 days after onset of ulcers)
- Appearance of the ulcer and, if present, regional lymphadenopathy that are typical for chancroid
- A negative test (HSV PCR test or HSV culture) for the presence of HSV in the ulcer exudate

LABORATORY TESTS

- Darkfield microscopy, RPR, HSV cultures, *H. ducreyi* culture, HIV testing recommended
- No FDA-cleared PCR test for *H. ducreyi* is available in the U.S.

TREATMENT

NONPHARMACOLOGIC THERAPY

Fluctuant nodes should be aspirated through healthy adjacent skin to prevent formation of draining sinus. Incision and drainage of ulcer not recommended because it delays healing and may lead to persistent sinus tract. Use warm compresses to remove necrotic material.

ACUTE GENERAL Rx

- Azithromycin 1 g PO (single dose) *or*
- Ceftriaxone 250 mg IM (single dose) *or*
- Ciprofloxacin 500 mg PO bid for 3 days *or*
- Erythromycin 500 mg PO qid for 7 days

NOTE: Ciprofloxacin is contraindicated in patients who are pregnant, lactating, or <18 yr.

- HIV-infected patients may need more prolonged therapy.
- In HIV-positive patients, failures have been reported with single-dose azithromycin and ceftriaxone regimens.

DISPOSITION

- All sexual partners of the patient within 10 days of the onset of symptoms should be treated with one of the previously discussed treatment regimens (see "Acute General Rx").
- Patients should be reexamined 3 to 7 days after initiation of therapy. Ulcers should improve symptomatically within 3 days and objectively within 7 days after initiation of successful therapy.
- Lack of improvement within 7 days should raise the possibility of co-infection with another organism, a resistant strain of *H. ducreyi*, HIV positive patient, or incorrect diagnosis.

PEARLS & CONSIDERATIONS

COMMENTS

- In the U.S. HSV-1 and syphilis are the most common causes of genital ulcers followed by chancroid, LGV, and granuloma inguinale.
- The combination of a painful genital ulcer and tender suppurative inguinal adenopathy suggests the diagnosis of chancroid.

Workowski KA et al: Sexually transmitted diseases treatment guidelines, *MMWR Recomm Rep* 64(RR-03):1-137, 2015.

BASIC INFORMATION

DEFINITION

In 1708, William Musgrave first coined the term *Charcot* to describe arthralgia associated with neuropathic joints caused by venereal disease. In 1868, Jean-Martin Charcot described Charcot with neuropathic disease caused by syphilis. Charcot arthropathy is a progressive condition following the loss of protective sensation; the hallmark features include pathologic fractures, dislocations, and gross foot and ankle deformities that can lead to ulceration, infection, and possible amputation. Charcot arthropathy is commonly associated with diabetes and diabetic peripheral neuropathy. Early recognition and diagnosis are imperative to avoid severe and irreversible foot deformities that may ultimately lead to catastrophic complications.

SYNONYMS

Neuropathic arthropathy
Charcot osteoarthropathy
Charcot neuropathic osteoarthropathy
Charcot arthropathy
Charcot foot
Charcot's joint

ICD-10CM CODES

M14.671	Charcot joint, right ankle and foot
M14.672	Charcot joint, left ankle and foot

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- The estimated prevalence of Charcot arthropathy is 0.1% to 7.5% in the general diabetic population.
- In patients with known diabetic neuropathy, the prevalence of Charcot arthropathy is approximately 35% and is not related to the type (type 1 or 2) of diabetes mellitus.
- Charcot is underdiagnosed by approximately 25%.
- Bilateral presentation is seen in 9% to 75% of patients.
- The midfoot is involved 70% of the time, followed by the forefoot and rear foot, each accounting for 15%.
- Observed in the fifth decade in diabetes mellitus type 1; observed in the sixth decade in diabetes mellitus type 2.
- Most patients with Charcot arthropathy have had diabetes mellitus for at least 10 yr.
- Unknown sex predilection and ethnic distribution.
- Risk factors include diabetic neuropathy, alcoholism, myelomeningocele, tabes dorsalis/syphilis, syringomyelia.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The natural history of Charcot arthropathy consists of four phases: Inflammation, fragmentation, coalescence, reconstruction.
- Inflammation phase: Erythema, edema, and calor. There is at least a 2° C (35.6° F) temperature difference between the involved limb and the contralateral foot. May present with mild pain or discomfort. Bounding pedal pulses. Typically, no radiologic osseous abnormalities are seen during the early acute phase. Early diagnosis is key.
- The tarso-metatarsal joints are most commonly involved, followed by the forefoot and hindfoot; a deformity in the foot may lead to unstable foot architecture.
- Fragmentation phase: As Charcot arthropathy progresses in the untreated state, osseous fragmentation and joint dislocation/subluxation occurs.
- Coalescence phase: Decreased local edema, coalescence of osseous fragments, ankylosis of joints, and new bone formation also take place during this phase.
- Reconstruction phase: Classic rigid deformity known as the "rocker bottom" foot occurs.
- Ulcerations may appear at any time during the acute and chronic stages of Charcot arthropathy.
- Distinguishing factors from Charcot arthropathy vs. diabetic peripheral neuropathy: Diabetic neuropathy is characterized by impairment of cold and warm thresholds whereas Charcot patients have preservation of warm stimuli, light touch, and peak skin blood flow at the toe.

ETIOLOGY

The most common cause of Charcot arthropathy is peripheral neuropathy associated with diabetes mellitus (Fig. E1). Less common conditions associated with Charcot arthropathy include syphilis (Fig. E2), alcoholism, spina bifida, poliomyelitis, Charcot-Marie-Tooth disease, leprosy, familial amyloid neuropathy, CNS/PNS tumors, pernicious anemia, cerebral vascular accident, lead poisoning, rheumatoid arthritis, multiple sclerosis, and trauma. Currently, three theories contribute to the etiology involved in this disease:

1. Neurotraumatic theory: Unperceived trauma or injury to an insensate foot. Osseous destruction is the result of unperceived sensory neuropathy with continued ambulation and repetitive stress. This repetitive microtrauma can lead to extensive bone destruction resulting in joint subluxation, dislocation, and pedal deformity.

FIG. E1 Diabetes mellitus and neuropathic arthritis. Note lateral displacement of metatarsals *(left)* and fragmentation and osseous debris *(right).* (From Goldman L, Ausiello D [eds]: *Cecil textbook of medicine,* ed 22, Philadelphia, 2004, Saunders.)

2. Neurovascular theory: Autonomic neuropathy, particularly sympathetic denervation, leads to arteriovenous shunting. This increase of blood flow into the bone causes demineralization of the bone and stimulates osteoclastic activity that causes bone destruction, leading to osteopenia.
3. Inflammatory theory: During the acute inflammation phase that is seen in Charcot arthropathy, the inflammatory cytokines, tumor necrosis factor-alpha, IL-1, and IL-6 are present. The role of these inflammatory cytokines is bone resorption by promoting osteoclastic proliferation and differentiation. Receptor activator of nuclear factor-kappa B ligand (RANKL) is responsible for activating osteoclasts in Charcot arthropathy. Osteoprotegerin is the antagonist of RANKL, and thus when this pathway is disrupted, osteoclastic activity predominates. The production of calcitonin gene-related peptide, which also antagonizes RANKL expression, is reduced in peripheral and autonomic neuropathy. Nitric oxide, which suppresses osteoclastic activity, has also been found to be dramatically decreased in Charcot arthropathy. Furthermore, advanced glycation end products are associated with increased RANKL activation. Hyperglycemia is the triggering factor for production of advanced glycation end products.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Abscess
- Osteomyelitis
- Cellulitis
- Gout
- Deep vein thrombosis
- Infectious arthritis/septic joint
- Osteoarthritis
- Complex regional pain syndrome
- Peripheral vascular disease
- Trauma

WORKUP

A thorough history and physical examination is the key to recognition of Charcot arthropathy. Early diagnosis requires an astute physician to be aware of the signs associated with acute Charcot, including but not limited to edema, erythema, and calor, which play a role in the inflammatory cascade. Testing for peripheral neuropathy should be performed utilizing methods such as electromyography, nerve conduction velocity tests, nerve biopsy if warranted, biothesiometer, and Semmes-Weinstein monofilament testing.

LABORATORY TESTS

Laboratory testing can be utilized to rule in or rule out diagnoses that may present with manifestations similar to those of Charcot arthropathy.

- The following labs may be ordered if warranted: Complete blood count with differential, basic metabolic panel, vitamin B_{12}, folate, RPR, ESR, CRP, uric acid, rheumatoid panel, joint aspiration, and bone biopsy.

FIG. E2 Syphilitic Charcot knee joints showing gross destructive changes. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

IMAGING STUDIES

- Plain x-rays may or may not show evidence of early osteomyelitis. Osseous findings will depend on the stage (inflammatory, development, coalescence, remodeling) of presentation of Charcot arthropathy.
- MRI can detect subtle changes in the early stages of active Charcot arthropathy. Findings include bone marrow edema, soft tissue edema, and subchondral fractures.
- Three-phase bone scan: Results are less accurate in the setting of diminished blood flow; thus, labeled white blood cell scanning can improve specificity.
- Positron emission tomography is currently being researched for an additional imaging modality to detect Charcot arthropathy.

Rx TREATMENT

ACUTE GENERAL TREATMENT

The most instrumental aspect of medical treatment of Charcot arthropathy is offloading. Offloading is accomplished with the use of total contact cast for approximately 12 to 18 wk pending clinical and radiographic assessment.

Once the acute phase has transpired, custom-molded insoles in accommodative diabetic shoe gear, Charcot restraint orthotic walker, and customized braces, just to name a few, can be utilized.

SURGERY: There is equivocal evidence to support whether surgical intervention is recommended during the acute phase of Charcot arthropathy. The goal of surgery is to achieve a plantigrade foot that allows ambulation without skin compromise. The general surgical indications include acute fracture dislocation or infection or when there is continued recurrence of ulceration. Arthrodesis is recommended for unstable pedal construct, and Achilles tendon lengthening to reduce forefoot pressure improves the overall pedal alignment. Amputation plays a role after failed arthrodesis and/or recurrent infections.

PHARMACOLOGIC THERAPY

Studies are currently being conducted to determine the efficacy of bisphosphonates whose mechanism of action is to decrease osteoclastic resorption and symptoms in active Charcot arthropathy.

DISPOSITION

Early recognition of Charcot arthropathy and consultation to a foot and ankle surgeon is essential in preventing the devastating complications associated with this disease.

PREVENTION

Appropriate glucose control in the diabetic patient is essential for preventing the sensory deficits that lead to Charcot arthropathy.

REFERRAL

Orthopedic surgeon or podiatrist with expertise in Charcot arthropathy
Endocrinology for diabetic blood glucose control

BASIC INFORMATION

DEFINITION

Charcot-Marie-Tooth (CMT) disease is the eponym that refers to a phenotypic and genetically diverse group of heritable sensory and motor polyneuropathies. These neuropathies may be demyelinating or axonal. The disease is classified as CMT1 if demyelinating and autosomal dominant, CMT2 if axonal and autosomal dominant, CMTX if X-linked disease, and CMT4 if demyelinating and autosomal recessive. A letter designates the specific gene (e.g., CMT1A refers to an autosomal dominant demyelinating neuropathy secondary to PMP22 duplications).

SYNONYMS

Peroneal muscular atrophy
Hereditary motor and sensory neuropathy (HMSN)
CMT

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Estimated prevalence is 1:2500, making CMT the most common inherited peripheral neuropathy and the most common inherited neuromuscular disease.
PREDOMINANT AGE: Affected individuals, which include both men and women, commonly present in the first or second decades of life. Less commonly, infants may be severely affected, or adults may develop minor symptoms after the age of 40.

GENETICS

- More than 90 genes have been reported to be causative of CMT.
- Inheritance may be autosomal dominant, recessive, X-linked recessive, or X-linked dominant. Spontaneous mutations may also occur.
- Mutations in four genes (PMP22, GJB1, MFN2, MPZ) account for more than 90% of genetically defined cases. Of these, PMP22 (peripheral myelin protein 22) duplications on chromosome 22 are the most frequent, accounting for approximately 50% of cases.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Although there is a spectrum of disease severity, most commonly, patients present with slowly progressive weakness, starting in the feet and ascending to the legs and arms over time.
- The first manifestations may be reported as clumsiness and inability to keep up with other children in sports. Patients may experience repeated tripping and a tendency to sprain their ankles.
- Over time weakness can progress, resulting in ambulation and balance difficulties and hand weakness.
- Muscle loss in the leg results in an "inverted champagne bottle" appearance. (Fig. E1A-B.)
- Up to 70% of patients develop foot deformities, including high arches (pes cavus) and hammer toes (flexion of the toes at the interphalangeal joint, metatarsophalangeal joint dorsiflexion). (Fig. E1C-D.) Up to 8% of patients may have flat feet (pes planus).
- Patients may not complain of significant sensory symptoms, though sensory loss will be apparent on examination.
- Reflexes are often absent in the ankles and may become reduced or absent in the proximal legs and in the arms over time.
- In some cases, enlargement of peripheral nerves results in enlarged palpable nerves.

ETIOLOGY

CMT has been reported to occur with mutations in more than 90 genes, which encode proteins involved in many neuronal and Schwann cell pathways, leading to disruption in normal cell functioning or myelin production.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other inherited neuropathies
- Distal myopathies
- Acquired peripheral neuropathies

WORKUP

- CMT should be suspected in childhood-onset peripheral neuropathies, especially those with a positive family history.
- Electrophysiologic studies are used to classify the neuropathy as either demyelinating or axonal and may distinguish acquired from hereditary demyelinating neuropathies.
- Genetic testing may confirm the diagnosis and aids in prognostication and family planning.
- In patients with the classic phenotype and evidence of demyelination on nerve conduction studies, the recommended first test is PMP22 duplications.
- If negative for PMP22 duplications or for axonal neuropathies, consider next-generation sequencing panels, which include many CMT-associated genes.
- The role of whole-exome or genome sequencing is uncertain at this time.

FIG. E1 Typical appearance of lower extremities in Charcot-Marie-Tooth. **A and B,** Wasting of the muscles of the lower extremities creating "inverted champagne bottle appearance." **C and D,** Typical appearance of hammer toes and pes cavus. (From Pareyson D, Marchesi C: Diagnosis, natural history, and management of Charcot-Marie-Tooth disease, *Lancet Neurology* 8:654, 2009)

TREATMENT

CHRONIC Rx

- There are no currently approved medications to cure or slow disease progression.
- Physical and occupational therapy are used for gait and balance training, improving strength, and to prevent tendon shortening.
- Orthotic devices, such as ankle–foot orthoses, help with gait and reduce falls.
- Surgical management for foot deformities can be considered when foot deformities cannot be corrected by orthotics or for intractable pain.
- Exercise appears to be safe and may improve strength and functioning.
- Neurotoxic medications (i.e., vincristine) should be avoided when possible.
- Modafinil can be considered to treat fatigue.

DISPOSITION

- In cases of CMT1A, progression is slow and patients remain ambulatory.
- Other forms of the disease may have more rapid progression and loss of ambulation.
- Life expectancy is not reduced.

REFERRAL

- Neurology or physical medicine and rehabilitation for care coordination
- Physical and occupational therapy for stretching, gait, and balance training
- Orthotist
- Genetic counselor
- Orthopedic surgery can be considered for intractable pain or foot deformities not amenable to orthotics

BASIC INFORMATION

DEFINITION

Chemotherapy-induced nausea and vomiting (CINV) refers to adverse emetic effects associated with the use of drugs used to treat cancer. There are five recognized subtypes:

- Acute-phase CINV: Nausea and vomiting start within minutes to hours after receiving chemotherapy.
- Delayed-phase CINV: Nausea and vomiting begin or return 24 hours or more after receiving chemotherapy.
- Breakthrough CINV: Occurring despite appropriate prophylactic treatment.
- Anticipatory CINV: Symptoms begin before receiving therapy as a conditioned response in patients who have developed significant nausea and vomiting during previous chemotherapy.
- Refractory CINV: Recurring in subsequent cycles of therapy, excluding anticipatory CINV.

SYNONYMS

Drug-induced nausea and vomiting
Chemotherapy-induced emesis
CINV

ICD-10CM CODES

R11.2	Nausea with vomiting, unspecified
R11.0	Nausea
R11.10	Vomiting, unspecified
Z51.11	Encounter for antineoplastic chemotherapy

EPIDEMIOLOGY & DEMOGRAPHICS

- The patient's risk for development of nausea and vomiting is most strongly dependent on the emetogenicity of the chemotherapy agent(s) being used (Table 1).
- Emetogenicity is classified into four categories: Highly emetic (>90%), moderately emetic (>30% to 90%), low emetic (10% to 30%), and minimally emetic (0% to 10%).
- With certain chemotherapy regimens, CINV will occur in the majority of patients. However, patients' tolerance may vary, and symptoms may occur in as low as 10% of patients.
- Symptoms may be dose dependent (the higher the dose, the greater the risk for symptoms).
- CINV is more likely to affect female and younger patients.
- Patients expecting CINV before receiving therapy (anticipatory emesis) are at greater risk of experiencing symptoms.
- Patients with a history of alcohol consumption are at lower risk.
- Patients with a history of motion sickness are at greater risk.

INCIDENCE: The highest incidence of CINV is before or during the first cycle of chemotherapy.
GENETICS: Some rapid metabolizers of certain 5-HT3 receptor antagonists and polymorphisms in the 5-HT3 receptor confer greater risk for CINV.

RISK FACTORS:

- Previous history of CINV
- History of motion sickness or vestibular dysfunction
- Higher levels of anxiety
- History of alcohol use decreases risk

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms may include anxiety and lightheadedness.
- The most common physical findings are increased pulse rate and abnormal blood pressure (elevated if the person is highly anxious, reduced if the patient is dehydrated).
- Symptoms such as diarrhea, fever, headache, and abdominal pain may suggest an alternative diagnosis; physical examination findings such as increased blood pressure, abdominal tenderness, or focal neurologic deficits may suggest symptoms caused by cancer progression or other acute illness such as infection.

PATHOPHYSIOLOGY

The pathophysiology of nausea and vomiting is illustrated in Fig. E1. CINV is likely the result of chemotherapy acting in two places: Directly in the gastrointestinal tract and in the vomiting center of the brain. In both areas, nausea and vomiting are mediated by the actions of certain neurotransmitters, with serotonin, dopamine, and neurokinin-1 being the most important.

TABLE 1 Emetogenic Potential of Commonly Used Oral Antineoplastic Agents

Risk	Frequency of Emesis (%; Without Prophylaxis)	Agent
High	>90	Altretamine
		Procarbazine
Moderate	30-90	Cyclophosphamide

Modified from Roila F et al: Guideline update for MASCC and ESMO in the prevention of chemotherapy and radiotherapy-induced nausea and vomiting: results of the Perugia consensus conference, *Ann Oncol.* 2010;21(suppl 5):v232-243.

Chemotherapy-Induced Nausea and Vomiting

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- The two main considerations are progression of cancer and infection
- Intestinal/gastric: Obstruction or partial obstruction of the digestive tract from tumor
- Neurologic: Metastases to the brain causing vomiting; metastatic infiltration of nerves affecting the digestive tract
- Infectious: Acute bacterial, viral, or parasitic infections of the digestive tract causing symptoms (can be associated with diarrhea or pain)
- Renal: Dehydration leading to acute kidney injury and failure, causing worsening of nausea and vomiting

WORKUP

No workup is indicated if patient's symptoms and onset of nausea and vomiting fit the usual presentation for CINV. If other symptoms or unexpected physical examination findings are present, then other causes need to be ruled out. A combination of blood work and imaging may be helpful.

LABORATORY TESTS

- If the onset of symptoms is not typical for CINV, then blood tests such as CBC, liver function tests, electrolytes, and kidney function tests may be indicated.
- Stool studies looking for infections from viruses, bacteria, or parasites may be ordered if diarrhea is also present.

IMAGING STUDIES

- Abdominal radiographs may be ordered to look for obstruction of the digestive tract but will not provide any information about tumor progression.
- Abdominal CT scan may provide more detailed information about local cancer progression/invasion in the proximity of the digestive tract and whether obstruction of the digestive tract is present.
- CNS imaging with CT scan or magnetic resonance imaging (MRI) of the brain may provide information about possible metastases.

TREATMENT

- A management approach to CINV is summarized in Box 1.
- Choice and duration of antiemetic use are dependent on the chemotherapy regimen used. Commonly used antiemetic agents and recommended dosing are described in Table 2.
- For chemotherapy agents with high emetogenic potential, the use of multidrug antiemetic regimens has proven to be highly effective in symptom prevention.
- The most common treatment combination includes a serotonin-receptor antagonist (ondansetron, granisetron, dolasetron, or palonosetron), a corticosteroid (methylprednisolone or dexamethasone), and a neurokinin-1 receptor antagonist (aprepitant, rolapitant, or fosaprepitant).
- A fixed-dose combination of oral palonosetron and netupitant (NK-1 receptor antagonist) is now available. Table 3 summarizes recommended antiemetic prophylaxis for patients receiving intravenous chemotherapy.
- Many other adjunct drugs are available, such as olanzapine, prochlorperazine, metoclopramide, haloperidol, and marinol; comparatively, they are less effective and have greater potential for adverse effects.
- Benzodiazepines (usually lorazepam) may help in patients with significant anxiety levels that lead to anticipatory CINV.
- Patients with uncontrolled symptoms may require hospitalization for supportive care including intravenous medications and fluids.

NONPHARMACOLOGIC THERAPY

For those patients with a significant anxiety component to their CINV, cognitive behavioral therapy may help.

DISPOSITION

Although CINV is one of the most feared complications of cancer therapy, its treatment has been revolutionized in the last 20 yr, with most patients achieving adequate symptom control.

PEARLS & CONSIDERATIONS

COMMENTS

- Aggressive symptom control in the acute phase of CINV is the key initial therapeutic approach. Prevention of the acute phase has led to much improved control of the delayed phase and has greatly decreased the incidence of anticipatory CINV.
- Prevention of symptoms is much easier to achieve than controlling or treating active symptoms.

SUGGESTED READINGS

Available at ExpertConsult.com

AUTHOR: **Byung Kim, MD**

BOX 1 Management Approach: Chemotherapy-Induced Nausea and Vomiting (CINV)

Antiemetic therapy for CINV should be based on the emetic potential of the chemotherapy regimen being used and should take into account individual patient factors (e.g., sex, age, history of alcohol use, and previous emesis with chemotherapy). Excellent methods for predicting the likelihood of emesis with single chemotherapeutic agents or combination regimens have been developed.

All patients receiving chemotherapy with moderate or high emetogenic potential should receive antiemetic prophylaxis for acute (day 1) and delayed (days 2 to 5) nausea and vomiting. Patients receiving highly emetogenic regimens should receive prophylaxis on day 1 with a 5-HT_3 receptor antagonist (preferably palonosetron) plus neurokinin-1 (NK1) receptor antagonist plus dexamethasone, followed on days 2 to 4 by dexamethasone. Olanzapine should be added in patients judged to be at high risk. For moderately emetogenic regimens, treatment with a 5-HT_3 receptor antagonist (preferably palonosetron) plus dexamethasone on day 1, followed by dexamethasone on days 2 and 3, is recommended.

Patients receiving therapy with low emetic potential should receive dexamethasone (8 mg intravenously or orally); a 5-HT_3 receptor antagonist should be added with subsequent courses only if antiemetic control is inadequate. Routine prophylaxis is not necessary for patients receiving agents or regimens of minimal risk. Patients with inadequate control should have intensification of their antiemetic prophylaxis during subsequent treatment cycles.

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 Antiemetic Agents: Recommended Dosing

	Recommended Dose	
Antiemetic Agent	**Acute Emesis (Before Chemotherapy)**	**Delayed Emesis**
5-HT_3 antagonists		
Ondansetron	0.15 mg/kg or 8 mg IV; 12-16 mg PO	8 mg PO twice a day × 2-3 days
Granisetron	1 mg IV or PO; 10 mg subcutaneous (extended release)	
Dolasetron	1.8 mg/kg or 100 mg IV; 100-200 mg PO	
Palonosetron	0.25 mg IV or 0.5 mg PO	
NK1 receptor antagonists		
Aprepitant	125 mg PO	80 mg PO days 2 and 3
Fosaprepitant	150 mg IV	
Rolapitant	180 mg PO	
Combination 5-HT_3/NK1 receptor antagonist		
NEPA (palonosetron 0.5 mg/netupitant 300 mg)	1 tablet PO	
Multireceptor antagonist		
Olanzapine	10 mg PO	10 mg PO days 2-4
Corticosteroids		
Dexamethasone		
With NK1 antagonist	12 mg IV or PO	8 mg PO for 2-3 days
Without NK1 antagonist	8 mg (moderate risk) or 20 mg (high risk) IV or PO	4-8 mg PO twice a day for 2-3 days
Other agents		
Prochlorperazine		10 mg PO or IV every 3-4 hours as needed
Lorazepam	1-2 mg IV (for anticipatory nausea/vomiting)	
Dronabinol		5 mg/m^2 PO every 3-4h as needed

5-HT_3, 5-Hydroxytryptamine 3; *NK1*, neurokinin 1; *IV*, intravenous; *PO*, by mouth.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

TABLE 3 Summary of Recommended Antiemetic Prophylaxis for Patients Receiving Intravenous Chemotherapy

Risk of Emesis	Day 1 (Prechemotherapy)	After Day 1
High (includes cyclophosphamide and doxorubicin)	5-HT_3 receptor antagonist (palonosetron preferred) + NK1 receptor antagonist + dexamethasone + olanzapine (if patient considered high risk)	Dexamethasone days 2-4 + aprepitant days 2-3 (if used on day 1) + olanzapine days 2-4 (high-risk patients)
Moderate	5-HT_3 receptor antagonist (palonosetron preferred) + dexamethasone	Dexamethasone days 2 and 3
Low	Dexamethasone	None
Minimal	As needed	None

5-HT_3, 5-Hydroxytryptamine 3; *NK1*, neurokinin 1.

Child Abuse and Neglect PTG ALG

BASIC INFORMATION

DEFINITION

Definition from the Federal Child Abuse Prevention and Treatment Act (CAPTA): Any recent act or failure to act on the part of a parent or caretaker that results in death, serious physical or emotional harm, sexual abuse or exploitation of a child; or an act or failure to act that presents an imminent risk of serious harm to a child. More specific definitions may be found in individual state criminal and Child Protective Services statutes.

- Neglect: Failure to provide for the basic needs of a child
  1. Physical neglect: Failure to provide necessary food, shelter, and supervision
  2. Medical neglect: Failure to provide necessary medical or mental health care
  3. Educational neglect: Failure to meet educational needs
  4. Emotional neglect: Failure to attend to emotional needs, exposure to domestic violence
  5. Abandonment: Child left and parents' whereabouts unknown or parents refuse to care for child
  6. Parental substance abuse: Includes prenatal exposure to mother's use of illicit drugs, manufacture of drugs (e.g., methamphetamine) in the presence of a child, selling or giving drugs to a child, use of mood-altering substance by caregivers that impairs their ability to provide care for a child
- Abuse: Act that causes harm or significant risk of harm to a child
  1. Physical abuse: Physical injury or significant risk of injury inflicted by a parent or caregiver intentionally, including in the course of excessive discipline
  2. Sexual abuse: When a child or adolescent is engaged in a sexual act, including sexual exploitation and child pornography
  3. Emotional/psychological abuse: Pattern of behavior of caretaker toward a child that impairs emotional development. This includes verbal abuse, cruelty, and threats
  4. Medical child abuse: Unnecessary, excessive, and potentially harmful medical care obtained at the instigation of a caregiver through exaggeration or falsification of symptoms

SYNONYMS

Child maltreatment syndrome
Physical abuse
Sexual abuse
Battered child syndrome
Shaken baby syndrome
Shaken impact syndrome
Abusive head trauma
Neglect

ICD-10 CM CODES

T74	Adult and child abuse, neglect or other maltreatment, confirmed
T74.02	Child neglect or abandonment, confirmed
T74.12	Child physical abuse, confirmed
T74.22	Child sexual abuse, confirmed
T74.32	Child psychological abuse, confirmed
T76.32XA	Child psychological abuse, suspected, initial encounter
T76.22XA	Child sexual abuse, suspected, initial encounter
T76.12XA	Child physical abuse, suspected, initial encounter
T74.32XA	Child emotional/psychological abuse
DSM-5	Code depends on specific diagnosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): The incidence of child maltreatment is universally underestimated due to children not disclosing abuse and neglect, the diagnosis of abuse being missed, and individuals not reporting abuse and neglect when it is identified. The following data are based on Child Protective Services (CPS) state aggregate as reported in *Child Maltreatment 2016*. These data typically include only those instances of abuse or neglect that would result in CPS involvement; therefore, physical or sexual abuse by neighbors, noncaregiving family members, teachers, and siblings may not be counted. In 2016, roughly 700,000 victims of child abuse or neglect were identified. This is a rate of 9.1 unduplicated victims per 1000 children.

- Types of abuse by percentage (note the total is greater than 100%, since children are often victims of more than one type of abuse).
  1. Neglect: 75%.
  2. Physical abuse: 18%.
  3. Sexual abuse: 8.5%.
  4. Psychological abuse: 5.6%.
  5. Medical neglect: 2.1%.
  6. Other: 6.9% (e.g., abandonment, threats of harm, congenital drug addiction).
- For 2016, an estimated 1700 child deaths were caused by abuse or neglect.
  1. Overall annual death rate resulting from abuse or neglect is estimated to be 2.25 deaths/100,000 children.
  2. 75% of these deaths were due to neglect alone or in combination with other forms of abuse; 44% were due to physical abuse, alone or in combination.
  3. 70% of these children were younger than 3 yr of age with 44% less than 1 yr old.
  4. Most fatalities were directly caused by one or both parents (78%).
  5. Of the states reporting this information, 5.7% of families had parental alcohol abuse, 15% had parental drug abuse, and 7.5% had inadequate housing.
  6. Many child abuse fatalities are underreported because of misdiagnosis or variations in state definitions and coding.
- 78% of abused children were victimized by one or both of their parents; however, most data collected by CPS involve caregivers.

PREDOMINANT SEX: There is a slight predominance of girls identified as victims. However, rates vary by age. Boys 5 and under have a higher rate of abuse, whereas girls 6 to 17 have higher rates of abuse. At all ages, boys have a higher child fatality rate than girls (2.48/100,000 for boys and 1.82/100,000 for girls).

PREDOMINANT AGE: Youngest children (0 to 3 yr old) have the highest rates of victimization, with 27% being younger than the age of 3.

GENETICS: No known genetic factors.

RISK FACTORS:

- Parent:
  1. Substance abuse
  2. Mental illness
  3. Intellectual impairment
  4. Parental history of being abused as a child
  5. Young age of parent
  6. Poor knowledge of child development leading to unrealistic expectations
- Child:
  1. Low birth weight or prematurity
  2. Chronic physical disability or illness
  3. Behavioral problems
  4. Developmental delay, intellectual disability, or expressive language disorders
  5. Unplanned, unwanted child
- Family:
  1. Social isolation
  2. Poor parent-child bonding
  3. Stress: Unemployment, chronic illness, eviction, arrest, poverty, military deployment
  4. Domestic violence
  5. Nonbiologically related adult male living in household
  6. Previous CPS involvement
- Community/society:
  1. Limited transportation
  2. Limited day care
  3. Unsafe neighborhoods
  4. Poverty

DIAGNOSIS

- Disclosures:
  1. For sexual abuse, often the only evidence is the child's disclosure.
  2. Document clearly any disclosures a child makes regarding abuse or neglect.
  3. When speaking with a young child who may have been abused or neglected, it is important to use forensically informed language and not ask direct or leading questions. The child may benefit from a referral to a Children's Advocacy Center for a forensic interview.
- Injuries:
  1. Documentation:
     a. Carefully document any injuries identified that may be the result of abuse or neglect.
     b. Photodocumentation of injuries is essential.
  2. Concerning history:
     a. The history of injury provided is incompatible with the developmental capabilities of the child.
     b. Changing history from the caregiver or a history that is different among caregivers.

c. The injury is not consistent with the mechanism provided by caregivers.
d. No history provided; especially with a nonmobile infant.
e. Delay in seeking care for a significant injury.

3. Concerning physical injuries:
   a. Patterned bruising (e.g., loop-shaped, two semicircles, rectangular, multiple parallel linear marks) (Table E1, Fig.E1).
   b. Bruising to the torso, ears, facial cheeks, jawline, upper arms and neck, especially in children under age 4 yr.
   c. Injury (bruise, burn, fracture, intracranial hemorrhage) in an infant who is not ambulatory and not cruising.
   d. Patterned burns, such as an impression of the burning object (lighter, iron, cigarette), immersion burns (Figs. E2 and E3).
   e. Certain fractures (especially in infants) are highly concerning for abuse: Metaphyseal, rib, sternum, scapula, vertebral body.
   f. Any injury that a child says is inflicted.
4. Sexual abuse:
   a. Most children who have been sexually abused will have a normal or nonspecific genital examination. A normal genital examination does not mean the child was not abused. History is the most important part of the diagnosis. Forensic interview by a trained professional is recommended, as is an examination by a health care provider experienced in sexual abuse evaluations.
   b. The identification of a sexually transmitted disease in a prepubertal child who is beyond the neonatal period is highly suspicious and, in some instances, almost diagnostic of sexual abuse. Reporting and further careful investigation are mandatory. Consult current CDC guidelines and a child sexual abuse expert for further guidance.

TABLE E1 Injury Patterns

Method of Injury/Implement	Pattern Observed
Grip/grab	Relatively round marks that correspond to fingertips and/or thumb
Closed-fist punch	Series of round bruises that correspond to knuckles of the hand
Slap	Parallel, linear bruises (usually petechial) separated by areas of central sparing
Belt/electrical cord	Loop marks or parallel lines of petechiae (the width of the belt/cord) with central sparing; may see triangular marks from the end of the belt, small circular lesions caused by the holes in the tongue of the belt, and/or a buckle pattern
Rope	Areas of bruising interspersed with areas of abrasion
Other objects/household implements	Injury in shape of object/implement (e.g., rods, switches, and wires cause linear bruising)
Human bite	Two arches forming a circular or oval shape, may cause bruising and/or abrasion
Strangulation	Petechiae of the head and/or neck, including mucous membranes; may see subconjunctival hemorrhages
Binding/ligature	Marks around the wrists, ankles, or neck; sometimes accompanied by petechiae or edema distal to the ligature mark Marks adjacent to the mouth if the child has been gagged
Excessive *hincar**	Abrasions/burns, especially to knees
Hair pulling	Traumatic alopecia; may see petechiae on underlying scalp, or swelling or tenderness of the scalp (from subgaleal hematoma)
Tattooing or intentional scarring	Abusive cases have been described, but can also be a cultural phenomenon (e.g., Maori body ornamentation)

*Punishment by kneeling on salt or other rough substance.
From Kliegman, RM: Nelson Textbook of Pediatrics, ed 21, Philadelphia, 2020, Elsevier.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis should include possible medical causes, accidental causes, and abuse.

BRUISING:
- Bleeding disorder (idiopathic thrombocytopenic purpura, hemophilia, leukemia, hemorrhagic disease of the newborn, von Willebrand disease)
- Connective tissue disorder (Ehlers-Danlos syndrome, vasculitis)
- Pigments (dermal melanocytosis)
- Dermatitis (phytophotodermatitis, nickel allergy)
- Folk treatment (coining, cupping)
- Accidental bruises

BURNS:
- Accidental burn
- Impetigo
- Folk treatment (moxibustion)
- Dermatitis (phytophotodermatitis)

INTRACRANIAL HEMORRHAGE:
- Accidental trauma
- Bleeding disorder with minor trauma
- Perinatal trauma (should resolve by 6 wk)

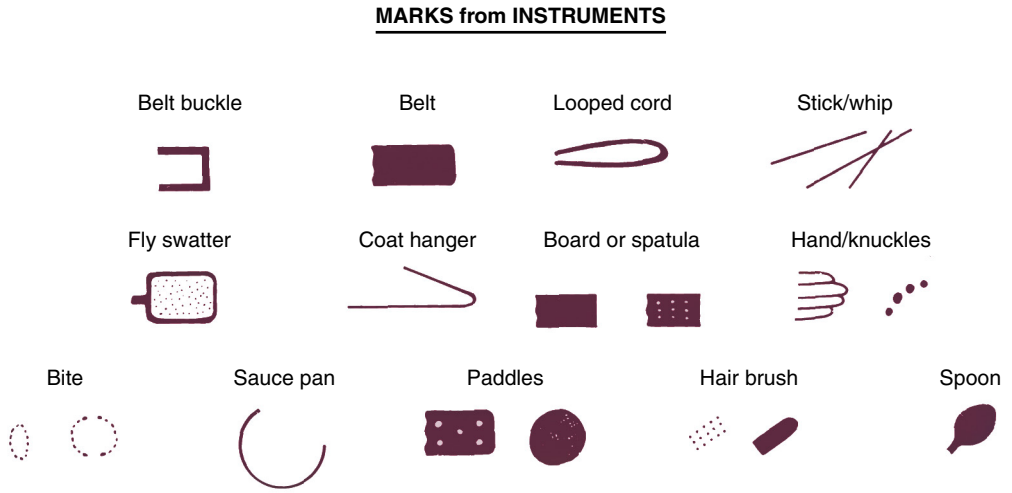

FIG. E1 A variety of instruments may be used to inflict injury on a child. Often the choice of an instrument is a matter of convenience. Marks tend to silhouette or outline the shape of the instrument. The possibility of intentional trauma should prompt a high degree of suspicion when injuries to a child are geometric, paired, mirrored, of various ages or types, or on relatively protected parts of the body. Early recognition of intentional trauma is important to provide therapy and prevent escalation to more serious injury. (From Kliegman, RM: Nelson Textbook of Pediatrics, ed 21, Philadelphia, 2020, Elsevier.)

- Arteriovenous malformation rupture
- Glutaric aciduria

FRACTURES:
- Accidental trauma
- Osteogenesis imperfecta
- Rickets
- Congenital syphilis
- Osteopenia of prematurity

SEXUAL ABUSE:
- Normal variants
- Lichen sclerosis et atrophicus
- Congenital abnormalities
- Urethral prolapse
- Hemangioma
- Nonsexually acquired infection (group A *Streptococcus, Shigella*)

WORKUP (FIG. E4)

History and physical examination:
- Careful history should be obtained and documented from all caregivers separately.
- Careful history should be obtained from the child. When children are less than 14 yr of age, history should be obtained in a forensically informed manner without asking direct or leading questions. A referral to a Children's Advocacy Center may be indicated.
- Scene investigation may be necessary and is typically conducted by law enforcement and/or CPS.
- Complete head-to-toe physical examination.
- Sexual abuse: Forensic interview and magnified examinations by trained professionals are the standard for evaluation and evidence collection. This is especially important to avoid further psychological or physical trauma to the child.

Laboratory tests to assess for bleeding disorder in the case of children with suspicious bruising. These tests may not be necessary if the abuse was witnessed or if the child has clear patterned bruising or other indicators of physical abuse:
- CBC with differential and platelets
- Prothrombin time, activated partial thromboplastin time
- Von Willebrand factor antigen and activity
- Factor VIII and IX levels
- Alanine aminotransferase, amylase, urinalysis should be considered in infants or other children with abdominal bruising to look for evidence of internal injury to the liver, pancreas, or kidneys

Laboratory tests to assess for bleeding disorder in the case of children with suspicious intracranial hemorrhage (ICH).
- CBC with differential and platelets
- Prothrombin time, activated partial thromboplastin time
- Factor VIII and IX levels
- Disseminated intravascular coagulation (DIC) panel

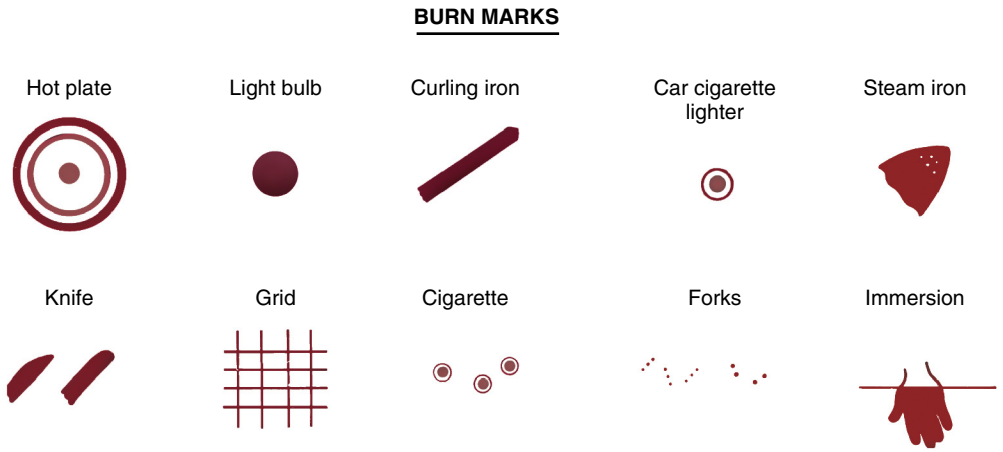

FIG. E2 Marks from heated objects cause burns in a pattern that duplicates that of the object. Familiarity with the common heated objects that are used to traumatize children facilitates recognition of possible intentional injuries. The location of the burn is important in determining its cause. Children tend to explore surfaces with the palmar surface of the hand and rarely touch a heated object repeatedly for long. (From Kliegman, RM: Nelson Textbook of Pediatrics, ed 21, Philadelphia, 2020, Elsevier.)

FIG. E3 Immersion injury patterns. **A,** Sparing of the flexoral creases. **B,** Immersion "stocking" burn. **C,** Immersion "glove" burn. **D,** Immersion buttocks burn. (From Jenny C: Child abuse and neglect: diagnosis, treatment, and evidence, Philadelphia, 2011, Saunders, p. 225, Fig 28-3 in Kliegman, RM: Nelson Textbook of Pediatrics, ed 21, Philadelphia, 2020, Elsevier.)

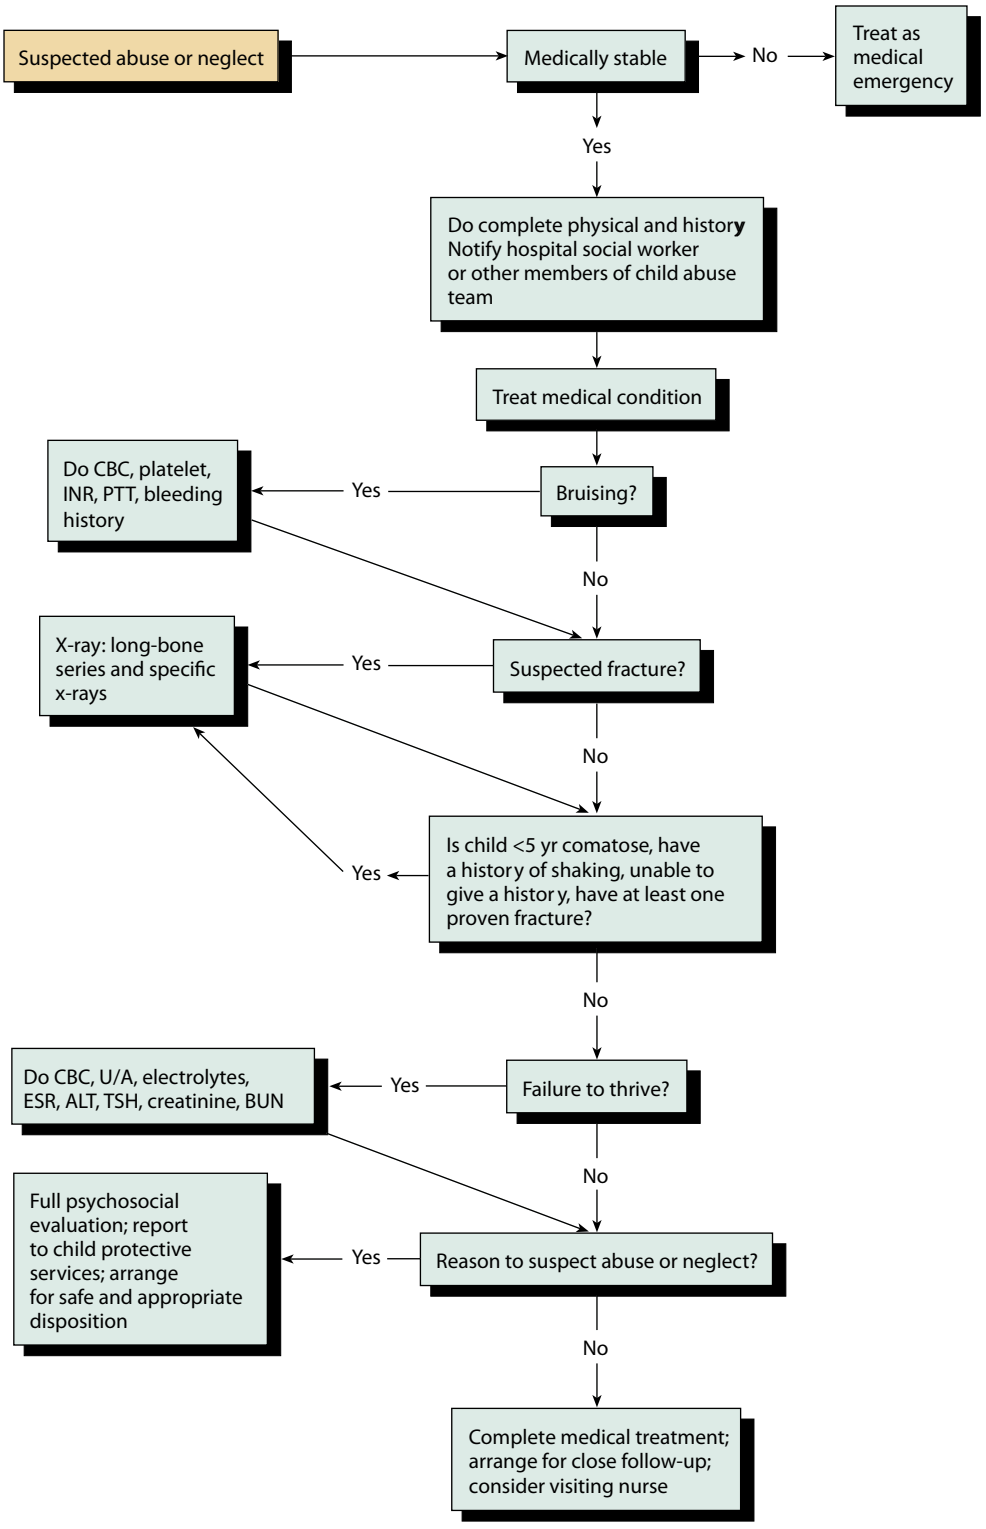

FIG. E4 Management of suspected child abuse. *ALT,* Alanine aminotransferase; *BUN,* blood urea nitrogen; *CBC,* complete blood count; *ESR,* erythrocyte sedimentation rate; *INR,* international normalized ratio; *PTT,* partial thromboplastin time; *TSH,* thyroid-stimulating hormone; *U/A,* urinalysis.

- Consultation with a child abuse expert physician should be strongly considered in children with suspicion of abusive head trauma

Laboratory tests for sexual abuse:

- If within 72 hr of acute sexual assault/abuse, a forensic evidence kit (rape kit) can be collected. Swabs are obtained from the oropharynx, areas of skin exposure (use an alternate light source or history provided to identify appropriate areas), genitalia, and rectum to send to the crime lab for DNA and other testing. Also collect samples of foreign hair, blood, saliva, or other tissue if present. Underwear and clothing can also be collected.
- Per current CDC recommendations, adolescent victims of acute assault should have appropriate specimens collected from sites of penetration or attempted penetration for *Neisseria gonorrhoeae* and *Chlamydia.* Nucleic acid amplification tests (NAATs) may be used and are preferred. In females, wet mount and culture or point-of-care (POC) testing of vaginal swab for *T. vaginalis* should also be done. If there is itching, vaginal

discharge, or malodor present, wet mount for bacterial vaginosis and *Candida* should also be done. Serum should be obtained for HIV, hepatitis B, and syphilis testing acutely. If negative, HIV and syphilis testing should be repeated 6, 12, and 24 wk after the assault.
- Child victims (i.e., prepubertal) should have specimens collected if testing for a sexually transmitted infection (STI) is clinically indicated. Gonorrhea and *Chlamydia* culture is the gold standard for diagnosis. If needed, vaginal specimens are to be collected by an experienced provider to avoid trauma to the child. Many providers now analyze specimens using urine or vaginal swabs with NAAT testing followed by culture confirmation or second NAAT if any positive results are obtained. The FDA has not approved NAAT testing for gonorrhea and *Chlamydia* of extragenital sites, so culture remains the gold standard. Testing for sexually transmitted infections (gonorrhea, *Chlamydia, T. vaginalis*, HIV, syphilis, and hepatitis) should be obtained if the child has a known STI, has symptoms of an STI, or if there is concern for sexual abuse that could result in an STI.

IMAGING STUDIES

Physical abuse:
- Radiographic skeletal survey for all children with suspicious injuries up to 2 yr. Additionally, a skeletal survey should be considered for any sibling less than 2 yr of age of a child who has been physically abused. Skeletal surveys can be done on children up to 5 yr of age when there are extenuating circumstances. A repeat skeletal survey should be done 2 wk after the initial skeletal survey. Adjunct imaging (MRI, ultrasound, bone scan) may be useful to further define suspicious lesions seen on plain films. Skeletal survey should conform to American College of Radiology Standards.
- Noncontrast head CT scan or MRI for all children <6 mo of age with concern of physical abuse. Head imaging should be considered for children 6 mo to 1 yr with concern of physical abuse. Children over 1 yr of age should have head imaging if neurological changes or per clinical judgment.
- When abusive head trauma is identified on head CT, a head MRI should be obtained.
- Abdominal CT scan if indicated by clinical examination or laboratory evaluation.
- Box E1 describes the specificity of radiologic findings for child abuse.

BOX E1 Specificity of Radiologic Findings for Child Abuse

High Specificity
Classic metaphyseal lesions
Rib fractures, especially posterior
Scapular fractures
Spinous process fractures
Sternal fractures

Moderate Specificity
Multiple fractures, especially bilateral
Fractures of different ages
Epiphyseal separations
Vertebral body fractures and sublux-ations
Digital fractures
Complex skull fractures

Common but Low Specificity
Subperiosteal new bone formation
Clavicular fractures
Long bone shaft fractures
Linear skull fractures

From Manaster BJ: *Musculoskeletal imaging—the requisites,* ed 3, Philadelphia, Mosby, 2006.

Rx TREATMENT

ACUTE GENERAL Rx

- Stabilize and treat acute medical injuries.
- Report to CPS. HIPAA allows reports for suspected child abuse without parental authorization.
- Report to law enforcement for suspected physical abuse or sexual abuse.
- Early report to CPS and/or law enforcement may allow for scene investigation.
- A safe disposition plan should be determined prior to discharge. This may involve coordination with the multidisciplinary team (physicians, law enforcement, family, and CPS). Disposition, once medically stable, is dependent on CPS. The child cannot be returned home if the environment is not safe.
- Physicians should remain available to discuss with investigators. This is often critical to determining the outcome of the case and placement of the child.
- Because follow-up of adolescent sexual assault victims can be difficult to coordinate, many experts recommend offering empiric treatment for STIs: Gonorrhea, *Chlamydia, Trichomonas,* and bacterial vaginosis. Pregnancy prophylaxis should also be offered. Hepatitis B immunization should be offered if not previously given. HIV prophylaxis is offered in certain situations depending on local epidemiology and type of assault. Consult local infectious disease experts for current recommendations. Repeat evaluation should be done in 2 wk for all victims of sexual assault, especially if they declined empiric treatment. If empiric treatment was not done, STI and pregnancy testing should be repeated at the 2-wk follow-up visit.
- Empiric treatment of child (i.e., prepubescent) who has been sexually abused is generally not recommended. This is especially important if NAATs are used for screening for STIs because confirmation is necessary for any positive results. Careful follow-up within 2 wk and treatment based on culture results are indicated. HIV prophylaxis is offered in certain circumstances according to local epidemiology and risk. Consult with a local infectious disease expert for further recommendations.

CHRONIC Rx

- Often depends on CPS and court-ordered interventions
- Treatment of parental mental illness
- Treatment of parental substance abuse, including requirements for random drug testing
- Instruction for parents in behavior management skills, including appropriate limit setting and discipline
- Anger management classes for parents
- Trauma-focused cognitive-behavioral therapy is an evidence-based practice for victims of sexual abuse and exposure to domestic violence; useful to include nonoffending parent/caregiver
- Ongoing individual and family therapy:
  1. Parent-child interactive therapy is an evidence-based practice that is used with young children with behavioral problems and parent-child relationship problems
  2. Child-parent psychotherapy is an evidence-based practice that is for young children (<5 yr) who have experienced a trauma and their caregivers
- May need long-term placement in foster care before it is safe to return home. In extreme cases of abuse, parental rights may be terminated without offering services

OUTCOMES

- Victims of chronic abuse and neglect:
  1. Have higher rates of mental illness (depression, suicide, posttraumatic stress disorder, eating disorders)
  2. Have more cognitive difficulties, often impaired academic performance
  3. Are more likely to become aggressive and have challenging behaviors
  4. Are more likely as adults to have adverse physical health outcomes (cardiovascular disease, cancer, STDs)
- Victims of abusive head trauma:
  1. One third die, one third have severe disability, one third appear normal in the short term

! PEARLS & CONSIDERATIONS

PREVENTION

- Home visitation by a specially trained nurse to high-risk families during pregnancy and infancy has shown positive outcomes (Nurse-Family Partnership).
- Anticipatory guidance at health visits to teach normal developmental expectations and appropriate discipline.
- Screening to identify at-risk or abused children.
- Targeted education in the newborn nursery for prevention of abusive head trauma has been shown to be effective.
- Substance abuse prevention and treatment.
- Identification and intervention for intimate partner violence.

Chlamydia Genital Infections

BASIC INFORMATION

DEFINITION

Genital infection with *Chlamydia trachomatis* (CT) is the most prevalent sexually transmitted disease in the U.S. Chlamydia infection can result in cervicitis, acute urethral syndrome, endometritis, pelvic inflammatory disease, ectopic pregnancy, infertility, and chronic pelvic pain in women (see "Pelvic Inflammatory Disease"). In men, CT infection may cause mucopurulent discharge, urethritis, epididymitis, and prostatitis. Newborns born via an infected birth canal are at risk for conjunctivitis and pneumonia. A majority of the men and women affected with CT are asymptomatic. Thus, screening tests play a very important role in detection of this infection to initiate treatment, impede disease sequelae, and prevent further transmissions.

ICD-10CM CODES

A56.2	Chlamydial infection of genitourinary tract, unspecified
A56	Other sexually transmitted chlamydial diseases
A56.0	Chlamydial infection of lower genitourinary tract
A56.00	Chlamydial infection of lower genitourinary tract, unspecified
A56.01	Chlamydial cystitis and urethritis
A56.02	Chlamydia vulvovaginitis
A56.09	Other chlamydial infection of lower genitourinary tract
A56.1	Chlamydial infection of pelviperitoneum and other genitourinary organs
A56.19	Other chlamydial genitourinary infection
A56.2	Chlamydial infection of genitourinary tract, unspecified
A56.3	Chlamydial infection of anus and rectum
A56.4	Chlamydial infection of pharynx
A56.8	Sexually transmitted chlamydial infection of other sites

EPIDEMIOLOGY & DEMOGRAPHICS

- *C. trachomatis* is the most commonly reported sexually transmitted disease in the U.S., with more than 1.5 million cases reported annually to the Centers for Disease Control and Prevention. However, it is thought that this number is an underestimate, since many cases of CT infection are asymptomatic and potentially can remain undiagnosed.
- Age is a strong predictor for risk of CT infection. Individuals less than 25 yr old are the largest age group affected by *C. trachomatis*. Chlamydia infections are 10 times more prevalent than gonococcal infections in young women between the ages of 18 and 26 yr.
- The prevalence of chlamydial infection varies according to race; according to a U.S. report in 2015, the rate of reported cases among African Americans was 5.9 times the rate among whites. The prevalence among sexually active non-Hispanic females of African descent 14 to 24 years of age was 13.5% as compared with 1.8% among non-Hispanic white females.[1]
- Chlamydia conjunctivitis occurs in 18% to 44% of infants, and chlamydial pneumonia occurs in 3% to 16% of infants who are delivered by mothers with untreated CT infection at the time of delivery.
- Pelvic inflammatory disease develops in 10% to 15% of women with untreated CT infections.
- Untreated CT increases a person's risk of acquiring HIV.
- In men, 15% to 55% of nongonococcal urethritis cases are caused by *C. trachomatis*.
- Table 1 summarizes clinical characteristics of common *C. trachomatis* infections.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical manifestations in symptomatic women affected with *C. trachomatis* are vaginal discharge or irregular vaginal bleeding. Purulent discharge or cervicitis may be visualized on speculum exam. Easily induced endocervical bleeding can be noted on exam and is caused by inflammation of endocervical columnar epithelium. Untreated infection can ascend the reproductive tract, causing pelvic inflammatory disease. Clinical signs of pelvic inflammatory disease are cervical, uterine, or adnexal tenderness on exam. Complications of pelvic disease are ectopic pregnancy, infertility, and chronic pelvic pain.

Most men are asymptomatic, but when they do experience symptoms, it is usually dysuria or a mucopurulent penile discharge. A complication that can arise from CT infection in men is epididymitis, which manifests as unilateral testicular pain, hydrocele, or swelling of the epididymis. An untreated CT infection can also cause prostatitis in men. Prostatitis may present as urinary dysfunction, pain with ejaculation, and pelvic pain.

Chlamydial conjunctivitis can be experienced by both men and women and is the result of conjunctiva exposed to infected genital secretions. CT infection can also cause proctitis or infection of the rectum in men and women. This usually presents with rectal pain, discharge, or bleeding. CT infection of the throat is usually asymptomatic in both men and women and not a usual cause of pharyngitis. Less frequent manifestations of CT infection may include perihepatitis (Fitz-Hugh–Curtis syndrome) or reactive arthritis (Reiter syndrome).

ETIOLOGY

- *C. trachomatis* consists of 15 serotypes
- Obligate, intracellular bacteria

[1]Wiesenfeld HC: Screening for Chlamydia trachomatis infections in women, *N Engl J Med* 376:765-773, 2017.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Differential diagnosis depends on presenting symptoms. Some of the common differentials are listed in the following:

- Candidiasis
- Conjunctivitis
- Ectopic pregnancy
- Endometriosis
- Gonorrhea
- Mycoplasma infection
- Pelvic inflammatory disease
- Trichomonas
- Urethritis
- Urinary tract infection

WORKUP

Individuals with signs and symptoms mentioned previously should be screened for CT infection. Since the majority of CT infections are asymptomatic, routine screening should be offered to individuals at risk for CT infection. Annual screening of all sexually active women less than 25 yr and women at any age at risk for sexually transmitted diseases is recommended. Risk factors include a new sexual partner, more than one sexual partner, individuals not in a mutually monogamous relationship, a previous or concurrent sexually transmitted disease, or working in the sex industry for profit. Screening interval is determined by any new risk for exposure since the last negative screening. The CDC recommends CT screening for all pregnant women under the age of 25 and for any pregnant woman over the age of 25 who is at increased risk for acquiring CT. These same pregnant women should be screened again during the third trimester.

LABORATORY TESTS

- Nucleic acid amplification tests (NAATs) are the gold standard for diagnosis because of their high sensitivity and specificity for the detection of CT infection. The FDA has approved these tests for male and female urine collection and for provider-collected endocervical, vaginal, and male urethral specimens.
- Rectal and pharyngeal collection site specimens may be taken from individuals who engage in receptive anal and oral intercourse, but these collection sites are not FDA approved.
- For best results, urine collection should be completed with a first-void urine sample.
- Self-collected vaginal swab samples for women have the same sensitivity and specificity as provider-collected samples.
- The same specimen can be used to test for chlamydia and gonorrhea.
- Sexual partners of a person testing positive for CT infection should be treated if they had sexual contact with that individual within 60 days prior to onset of symptoms or CT diagnosis.
- Microscopy should not be used for chlamydia diagnosis; however, greater than 10 white

TABLE 1 Clinical Characteristics of Common *Chlamydia trachomatis* Infections

	Infection	Symptoms and Signs	Presumptive Diagnosis	Definitive Diagnosis	Treatment
Men	Nongonococcal urethritis	Urethral discharge, dysuria	Urethral leukocytosis; no gonococci seen	Urine or urethral NAAT	Azithromycin, 1 g PO (single dose) *Or* Doxycycline, 100 mg PO bid, for 7 days
	Epididymitis	Unilateral epididymal tenderness, swelling; pain; fever, presence of NGU	Urine or urethral NAAT	Urethral leukocytosis; pyuria on urinalysis	STI likely: Ceftriaxone 250 mg IM plus doxycycline, 100 mg PO bid, for 10 days *History of insertive anal intercourse:* Ceftriaxone, 250 mg IM, plus levofloxacin, 500 mg bid for 10 days
	Proctitis (non-LGV)	Rectal pain, discharge and bleeding; history of receptive anal intercourse	≥1 PMN/OIF on rectal Gram stain; no gonococci seen	Urine or urethral NAAT; rectal culture or NAAT	Doxycycline, 100 mg PO bid, for 7 days
	LGV	Painful, tender inguinal lymphadenopathy, fever	"Groove sign"	Urine, urethral, lymph node or rectal NAAT; rectal or lymph node culture; LGV-specific testing if available	Doxycycline, 100 mg PO bid, for 21 days
	LGV proctitis	Rectal pain, discharge, and bleeding in MSM; absence of inguinal lymphadenopathy	≥1 PMN/OIF on rectal Gram stain; no gonococci seen	Urine, urethral, or rectal NAAT; rectal culture; LGV-specific testing if available	Doxycycline, 100 mg PO bid, for 21 days
	Conjunctivitis	Ocular pain, redness, discharge; simultaneous genital infection	Gram stain of conjunctival swab negative for bacterial pathogens; PMNs on smear	Rectal culture or NAAT; NAAT of conjunctivae	Azithromycin, 1 g PO (single dose) *Or* Doxycycline, 100 mg PO bid, for 7 days
Women	Cervicitis	Mucopurulent cervical discharge; ectopy, easily induced bleeding	≥20 PMN/OIF on cervical Gram stain	Urine or cervical NAAT	Azithromycin, 1 g PO (single dose) *Or* Doxycycline, 100 mg PO bid, for 7 days
	Urethritis	Dysuria, frequency; no hematuria	Pyuria on UA; negative urine Gram stain and culture	Urine, cervical, or urethral NAAT	Azithromycin, 1 g PO (single dose) *Or* Doxycycline, 100 mg PO bid for 7 days
	Pelvic inflammatory disease	Lower abdominal pain, adnexal pain, cervical motion tenderness	Evidence of mucopurulent cervicitis	Urine or cervical NAAT	Outpatient: Ceftriaxone 250 mg IM as a single dose, plus doxycycline 100 mg PO bid for 14 days, with or without metronidazole, 500 mg PO bid for 14 days
Adults	Conjunctivitis	Ocular pain, redness, discharge; simultaneous genital infection	Gram stain of conjunctival swab negative for bacterial pathogens; PMNs on smear	DFA or NAAT on conjunctival swab	Azithromycin, 1 g PO (single dose) *Or* Doxycycline, 100 mg PO bid for 7 days
Newborns	Conjunctivitis	Ocular pain, redness, discharge; simultaneous genital infection	Gram stain of conjunctival swab negative for bacterial pathogens; PMNs on smear	DFA or NAAT on conjunctival swab; vagina, rectum, pharynx also often positive	Erythromycin base 50 mg/kg/day, orally divided into four doses daily for 14 days; evaluate and treat parents as well
	Pneumonia	Staccato cough, tachypnea, hyperinflation	Diffuse interstitial infiltrate, eosinophilia	Nasopharyngeal NAATs or culture; MIF serology (IgM)	Erythromycin base 50 mg/kg/day, orally divided into four doses daily for 14 days; evaluate and treat parents as well

DFA, Direct fluorescent antibody; *IgM*, immunoglobulin M; *LGV*, lymphogranuloma venereum; *MIF,* microimmunofluorescence; *MSM,* men who have sex with men; *NAAT,* nucleic acid amplification test; *NGU*, nongonococcal urethritis; *OIF,* oil immersion field; *PMN*, polymorphonuclear neutrophil; *STI*, sexually transmitted infection; *UA*, urinalysis.

From Bennett JE, Dolin R, Blaser MJ. *Mandell, Douglas, and Bennett's principles and practice of infectious diseases*, ed 8, Philadelphia, 2015, Saunders.

blood cells per high-power field with a mucopurulent discharge can be a presumptive diagnosis.

Rx TREATMENT

ACUTE GENERAL Rx

Nongonococcal urethritis, urethritis, cervicitis, conjunctivitis (except for lymphogranuloma venereum):

- Azithromycin 1 g PO × single dose therapy *or*
- Doxycycline 100 mg PO bid for 7 days

Infection in pregnancy:

- Azithromycin 1 gm PO single-dose therapy

Alternatives:

- Erythromycin 500 mg PO qid for 7 days *or*
- Erythromycin ethylsuccinate 800 mg PO qid for 7 days

NOTE: Azithromycin (Pregnancy Risk Category B) is generally considered safe and effective during pregnancy and with lactation. Erythromycin base (Pregnancy Risk Category B) is an acceptable alternate agent for treatment of CT infection in pregnancy. Doxycycline is contraindicated in pregnancy. Erythromycin estolate is contraindicated in pregnancy because of drug-related hepatotoxicity.

FOLLOW-UP:

- Observed single-dose therapy should be offered to individuals for whom compliance is a concern.
- To minimize disease transmission to partners, affected persons should be advised to refrain from sexual intercourse for 7 days after single-dose therapy, until completion of 7-day therapy, or until resolution of symptoms.
- To prevent reinfection, affected individuals should refrain from sexual intercourse until all of their partners have been treated.
- Test of cure to detect treatment failure is not needed.
- Re-collection by NAAT method in less than 3 weeks from treatment can yield a false-positive result due to the sensitivity of this testing method.
- Both men and women treated for chlamydia should be retested at approximately 3 months after treatment to screen for reinfection. If patients do not return to clinical settings within 3 months, rescreen the patient at the next presentation for clinical care.
- Pregnant women with *Chlamydia trachomatis* infection should have a test of cure 3 to 4 weeks after treatment and should then be retested within 3 months.

Refer partners for evaluation and treatment.

RECURRENT AND PERSISTENT URETHRITIS: Retreat noncompliant patients with the above regimens. If patient was initially compliant, recommended regimens: Metronidazole 2 g PO in single dose plus erythromycin base 500 mg PO qid for 7 days or erythromycin ethylsuccinate 800 mg PO qid for 7 days.

REFERRAL

Refer to infectious disease specialist if persistent infection or gynecologist if salpingitis is suspected.

Cholangiocarcinoma

BASIC INFORMATION

DEFINITION

Cholangiocarcinoma is a cancer that originates from the epithelial lining of bile ducts. Most commonly an adenocarcinoma, this tumor is classified based on its location within the biliary tree as intrahepatic, perihilar, or extrahepatic.

SYNONYM

Bile duct carcinoma

ICD-10CM CODES

C22.1	Intrahepatic bile duct carcinoma
C24.0	Malignant neoplasm of extrahepatic bile duct

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- The incidence rate of cholangiocarcinoma varies by region. A low rate of 1 to 2 per 100,000 occurs in the U.S., while incidence peaks at 80 per 100,000 in Thailand.
- Incidence rate of intrahepatic cholangiocarcinoma appears to be increasing.
- Higher incidence in Hispanic and Asian populations.

PREDOMINANT SEX AND AGE:

- Slightly more common in men
- Most often diagnosed between 50 and 70 yr of age
- Patients with primary sclerosing cholangitis (PSC) can present as early as 30 yr old

RISK FACTORS:

- PSC causes inflammation of the bile ducts leading to fibrosis and stricturing of the biliary tree. PSC is the most common risk factor for development of cholangiocarcinoma, with a lifetime risk of up to 15%.
- Other risk factors include infection with hepatitis B and C, liver cirrhosis, chronic hepatolithiasis, choledochal cysts, and parasitic infections of the liver.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- With early-stage cholangiocarcinoma, the patient may be completely asymptomatic, and diagnosis is made incidentally on imaging or during the workup for elevation of liver enzymes.
- Later-stage cholangiocarcinoma may present as biliary obstruction.
- The clinical presentation is also dependent on the location of the tumor. Cholangiocarcinoma involving the intrahepatic ducts tends to cause nonspecific symptoms of dull, aching right upper quadrant pain and weight loss. A tumor of the extrahepatic ducts most often causes symptoms of biliary obstruction including jaundice, pale stools, and dark urine.
- Findings on physical examination may include jaundice, pain on palpation of the right upper quadrant, hepatomegaly, and fever.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes other conditions that may cause right upper quadrant pain, fever, and symptoms of biliary obstruction or those that present with a mass on imaging.

- Primary sclerosing cholangitis
- Choledocholithiasis
- Acute cholangitis
- Liver metastases
- Pancreatic head cancer

WORKUP

Fig. E1 describes an algorithm for the diagnosis of intrahepatic cholangiocarcinoma. The approach to the diagnosis of perihilar cholangiocarcinoma is summarized in Fig. E2. The Bismuth-Corlette classification of cholangiocarcinoma based on location is illustrated in Fig E3. Staging of cholangiocarcinoma is described in Table E1.

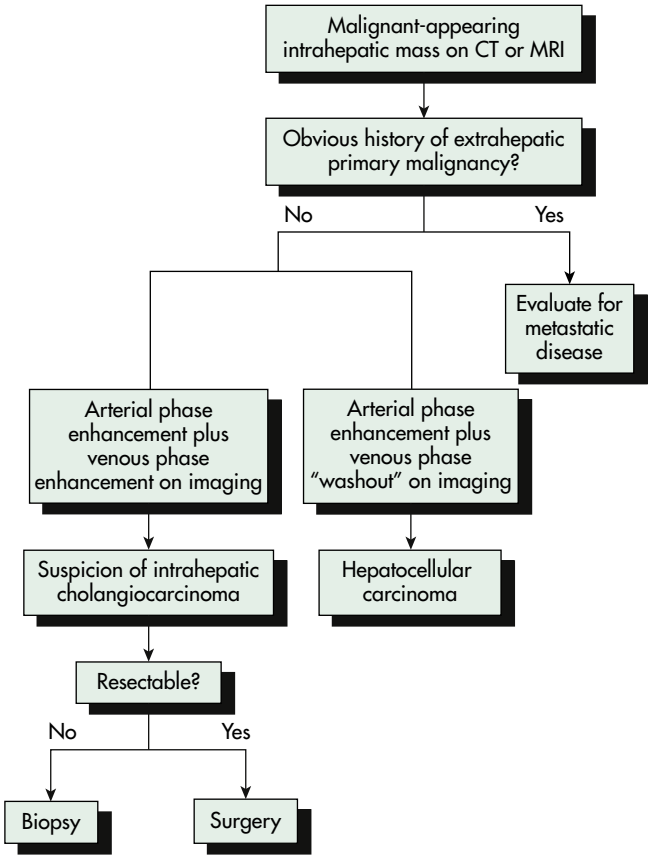

FIG. E1 Algorithm for the diagnosis of intrahepatic cholangiocarcinoma. In cases of an intrahepatic mass lesion and in the absence of known extrahepatic primary malignancy, dynamic imaging with either computed tomography *(CT)* or magnetic resonance image *(MRI)* of the liver should be performed. Contrast enhancement throughout the arterial phase with "washout" in the portal venous phase indicates a hepatocellular carcinoma. Contrast enhancement throughout the arterial and portal venous phases should raise the suspicion of an intrahepatic cholangiocarcinoma; in such cases, the resectability of the tumor should be determined. If the lesion is deemed resectable, the patient should be referred for surgical resection without biopsy. If an intrahepatic cholangiocarcinoma is deemed unresectable, a biopsy should be performed to confirm the diagnosis and guide appropriate treatment. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

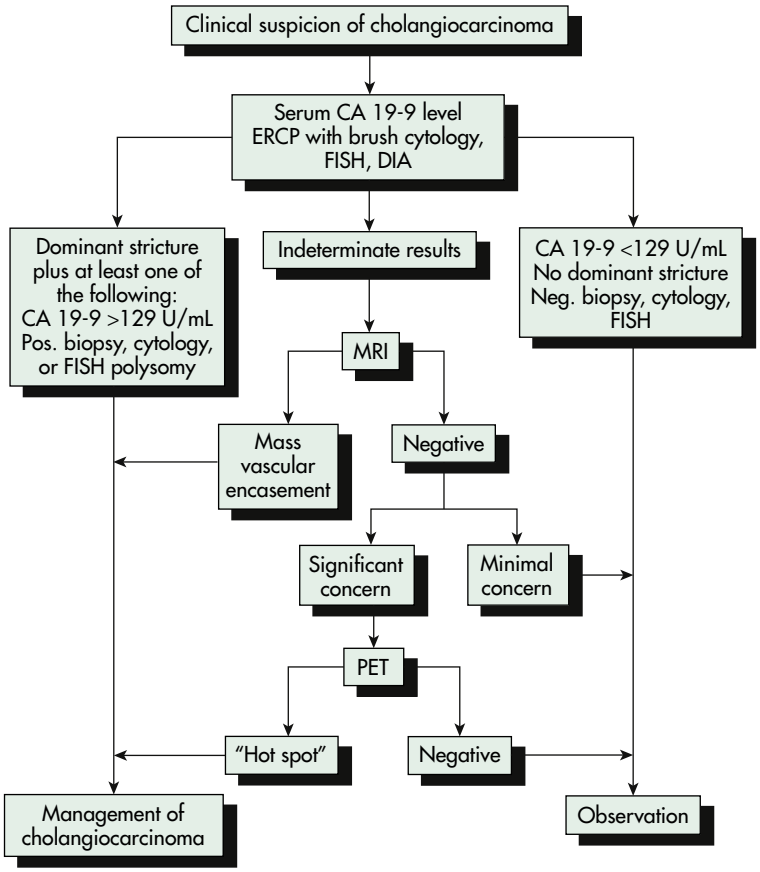

FIG. E2 Algorithm for the diagnosis of perihilar cholangiocarcinoma. In cases of clinically suspected perihilar cholangiocarcinoma, a serum CA 19-9 level, ERCP, and conventional as well as molecular cytologic analysis of endoscopically obtained biliary brushings of malignant-appearing areas should be performed. If the results of these tests are normal or negative, close follow-up of the patient is recommended. Management of cholangiocarcinoma should be prompted by identification of a dominant stricture, a serum CA 19-9 level above 129 U/ml, or a biopsy or cytology result that is positive for carcinoma or polysomy. In indeterminate cases, gadolinium-enhanced magnetic resonance image *(MRI)* of the liver is recommended. If a mass lesion or vascular encasement is identified, management of cholangiocarcinoma should be initiated. If the MRI study is negative but clinical concern about cholangiocarcinoma persists, PET can be performed. If "hot spots" are identified on PET (positive result), treatment for cholangiocarcinoma should be initiated. If the result of the PET scan is negative, close follow-up of the patient is recommended. If MRI is negative and cholangiocarcinoma is considered unlikely, the patient can be followed expectantly. *DIA,* Digital image analysis; *ERCP,* endoscopic retrograde cholangiopancreatography; *FISH,* fluorescence in situ hybridization; *neg.,* negative; *PET,* positron emission tomography; *pos.,* positive. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

LABORATORY TESTS

- Liver enzymes
- INR
- Bilirubin

Blood work may reveal an "obstructive pattern" with predominant elevation of alkaline phosphatase and bilirubin.

Tumor markers:

- CEA
- CA19-9

It is important to note that these tumor markers may be elevated even in the setting of benign inflammation of the biliary tree, for example, during an episode of acute cholangitis. These markers are neither sensitive nor specific for cholangiocarcinoma, but if they are elevated at the time of diagnosis, they may be helpful in tracking response to therapy or in monitoring for disease recurrence.

IMAGING STUDIES

Abdominal ultrasound (Fig. E4):

- Initial test of choice in patients presenting with nonspecific symptoms of obstruction or elevated liver enzymes.

CT scan/magnetic resonance cholangiopancreatography (MRCP):

- Improved visualization of the biliary tree to allow for identification of the tumor, level of obstruction, and extent of disease.

Endoscopic retrograde cholangiopancreatography (ERCP) (Fig. E5):

- Can be used to obtain brushings or biopsies of the biliary tree, but diagnostic yield is poor (35% to 86%), and there is a risk of cholangitis in patients with significant obstruction of bile drainage.

Endoscopic ultrasound (EUS):

- Allows local ultrasound visualization of tumor extent and regional lymphadenopathy, as well as diagnostic fine-needle aspiration of distal biliary duct tumors and involved lymph nodes.

Rx TREATMENT

ACUTE GENERAL Rx

- The only curative treatment option for cholangiocarcinoma is surgical extirpation. Eligibility for surgical resection with curative intent is based both on the location of the tumor and the stage of disease. Box E1 summarizes criteria for unresectability of perihilar cholangiocarcinoma.
- Surgical approaches include partial liver resection, pancreaticoduodenectomy, pancreaticojejunostomy, or even liver transplantation in carefully selected patients.

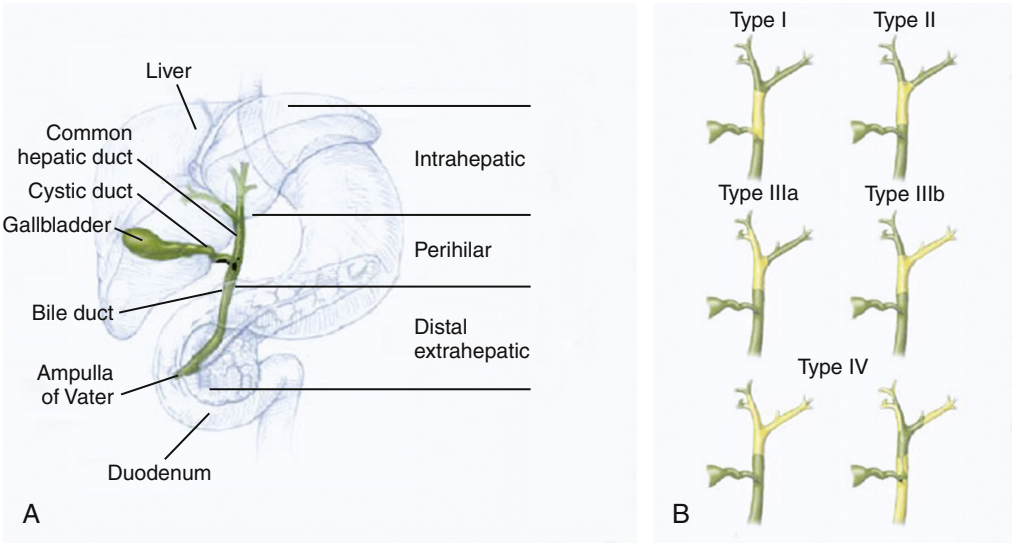

FIG. E3 Classification of cholangiocarcinoma. A, Anatomic classification of intrahepatic, perihilar, and extrahepatic cholangiocarcinoma. **B,** Bismuth-Corlette classification of hilar cholangiocarcinoma as types I to IV. Tumor is depicted in yellow and normal bile ducts in green. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

TABLE E1 TNM and American Joint Committee on Cancer (AJCC)/International Union Against Cancer (UICC) Staging Systems for Intrahepatic Cholangiocarcinoma

TNM Stage	Criteria
T_x	Primary tumor cannot be assessed
T_0	No evidence of primary tumor
T_{is}	Carcinoma in situ (intraductal tumor)
T_1	Solitary tumor without vascular invasion
T_{2a}	Solitary tumor with vascular invasion
T_{2b}	Multiple tumors, with or without vascular invasion
T_3	Tumor perforating the visceral peritoneum or involving the local extrahepatic structures by direct invasion
T_4	Tumor with periductal invasion
N_x	Regional lymph nodes cannot be assessed
N_0	No regional lymph node metastases
N_1	Regional lymph node metastases present
M_0	No distant metastases
M_1	Distant metastases

AJCC/UICC Stage	Tumor	Node	Metastasis
0	T_{is}	N_0	M_0
I	T_1	N_0	M_0
II	T_2	N_0	M_0
III	T_3	N_0	M_0
IV A	T_4	N_0	M_0
	Any T	N_1	M_0
IV B	Any T	Any N	M_1

TNM, Tumor, node, metastasis.
From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.

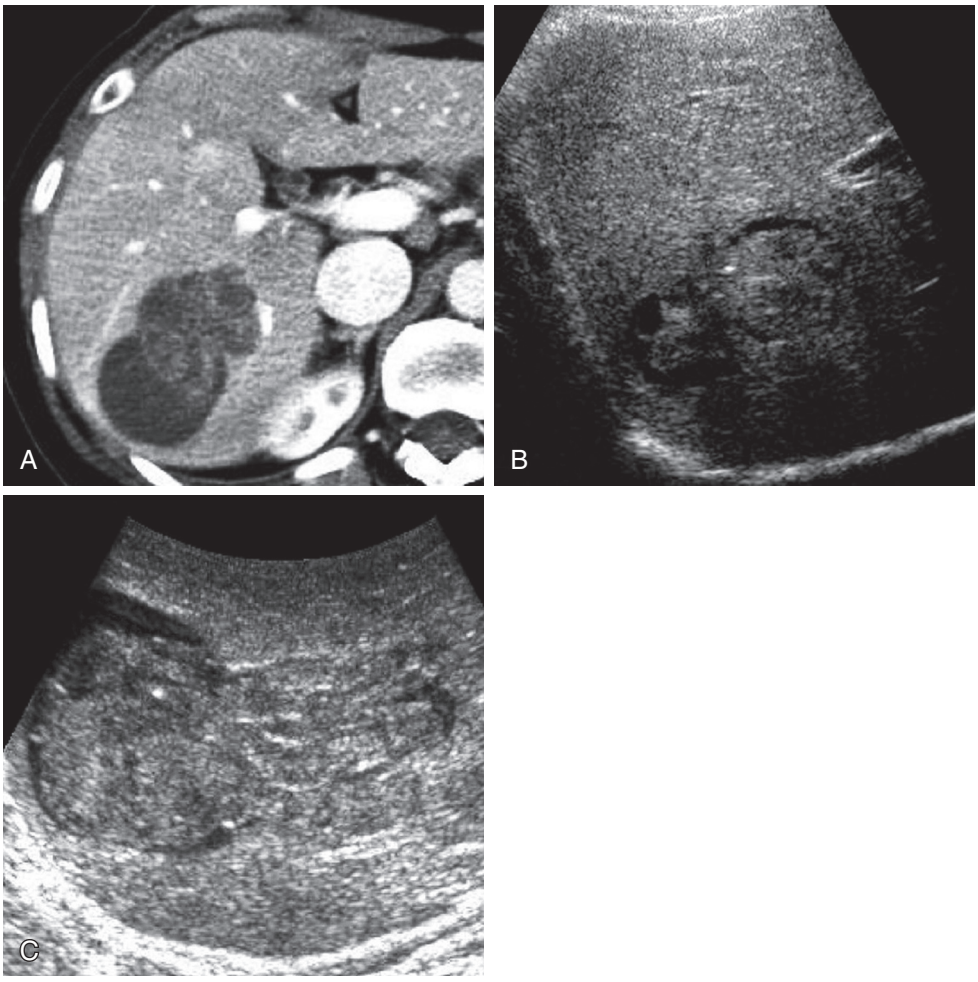

FIG. E4 Intraductal intrahepatic cholangiocarcinoma. A, Computed tomography scan, and **B,** ultrasound view, show a solid and cystic mass in the right lobe of the liver. **C,** Intraoperative sonogram demonstrates the mass to lie entirely within an extremely dilated duct. Low-grade cholangiocarcinoma was found at pathologic examination. (From Rumack CM et al: *Diagnostic ultrasound*, ed 4, Philadelphia, 2011, Mosby.)

- Adjuvant chemotherapy, gemcitabine and cisplatin, has been shown to reduce mortality in patients with both positive margins post-resection and/or involved lymph nodes.
- The use of adjuvant radiation remains an area of controversy, but there is evidence of improved survival in inoperable patients with localized disease.
- In the setting of biliary obstruction, stenting via ERCP or percutaneous drain insertion should be performed to facilitate bile flow and avoid stasis.

DISPOSITION

- Surveillance imaging for recurrence is recommended every 6 months for a total of 2 yr.
- Recurrence can occur locally or as metastatic disease, most commonly to liver, lung, or peritoneum.
- Five-yr survival rates vary between 15% and 60% based on the stage of disease. Unfortunately, even those patients with node-negative disease who undergo resection with curative intent have a high rate of disease recurrence.

REFERRAL

Referral should be made to a hepatobiliary surgeon for consideration of surgical resection and to a medical oncologist for possible adjuvant chemotherapy.

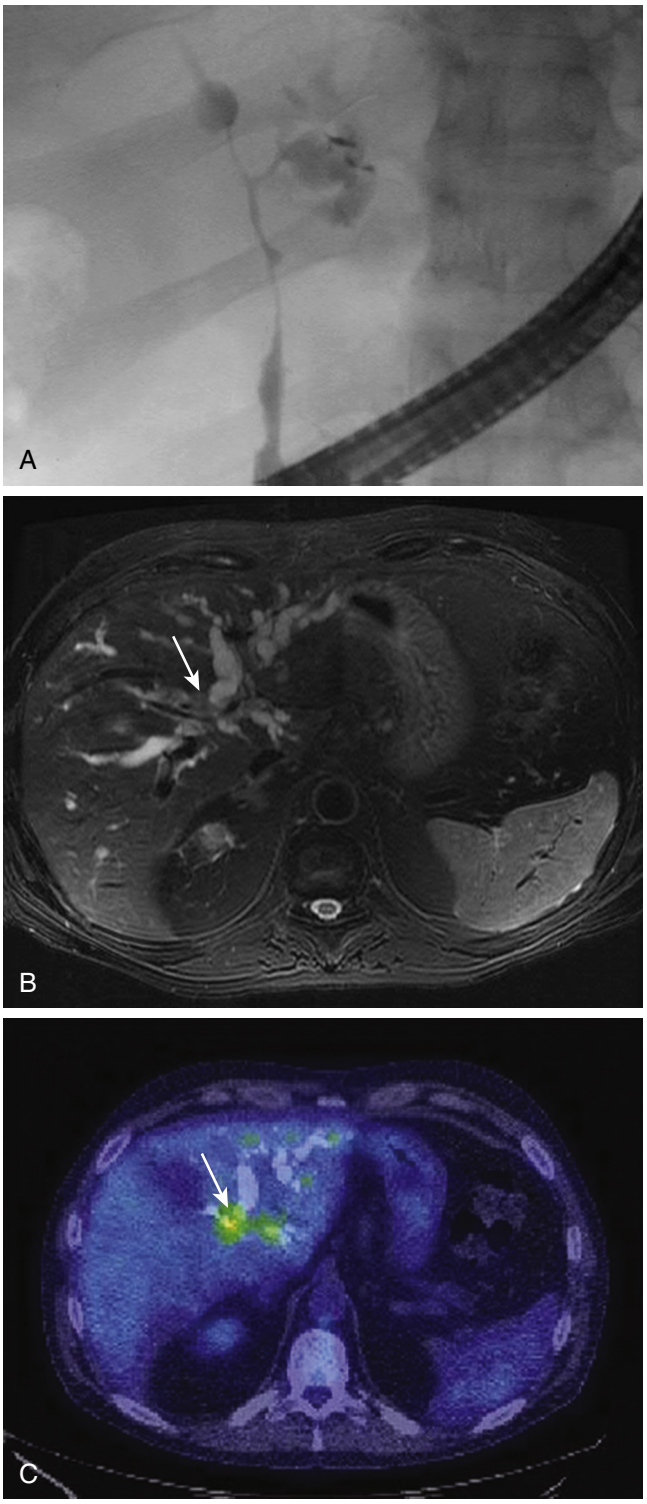

FIG. E5 Imaging of extrahepatic cholangiocarcinoma. A, Film from endoscopic retrograde cholangiography in a patient with perihilar cholangiocarcinoma demonstrating dominant strictures of the biliary tract consistent with Bismuth-Corlette type IV. **B,** Gadolinium-enhanced magnetic resonance image with ferumoxide in the same patient. The *arrow* points to the biliary tumor seen on a T2-weighted image. **C,** Positron emission tomography/computed tomography scan of the same patient. The biliary tumor is seen as an enhancing region *(arrow)*. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

BOX E1 Criteria for Unresectability of Perihilar Cholangiocarcinoma

Atrophy of one liver lobe with encasement of the contralateral portal vein branch
Atrophy of one liver lobe with contralateral secondary biliary radical involvement
Bilateral portal vein branch encasement
Bilateral hepatic artery encasement
Distant lymph node metastases
Hilar cholangiocarcinoma, Bismuth-Corlette type IV
Intrahepatic or distant metastases
Primary sclerosing cholangitis
Significant comorbid conditions

From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.

BASIC INFORMATION

DEFINITION

Cholangitis refers to an inflammation and/or infection of the hepatic and common bile ducts associated with obstruction of the common bile duct.

SYNONYMS

Biliary sepsis
Ascending cholangitis
Suppurative cholangitis

ICD-10CM CODE
K83.0 Cholangitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Complicates approximately 1% of cases of cholelithiasis
PEAK INCIDENCE: Seventh decade
PREVALENCE (IN U.S.): 2 cases/1000 hospital admissions
PREDOMINANT SEX:
- Females, for cholangitis secondary to gallstones
- Males, for cholangitis secondary to malignant obstruction and HIV infection

PREDOMINANT AGE: Seventh decade and older; unusual <50 yr of age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Usually acute onset of fever, abdominal pain (RUQ), and jaundice (Charcot triad)
- All signs and symptoms in only 50% to 85% of patients
- Often, dark coloration of the urine resulting from bilirubinuria
- Complications:
  1. Bacteremia (50%) and septic shock
  2. Hepatic abscess and pancreatitis

ETIOLOGY

Obstruction of the common bile duct causing rapid proliferation of bacteria in the biliary tree
- Most common cause of common bile duct obstruction: Stones, usually migrated from the gallbladder
- Other causes: Prior biliary tract surgery with secondary stenosis, tumor (usually arising from the pancreas or biliary tree), and parasitic infections from *Ascaris lumbricoides* or *Fasciola hepatica*
- Iatrogenic after contamination of an obstructed biliary tree by endoscopic retrograde cholangiopancreatoscopy (ERCP) or percutaneous transhepatic cholangiography (PTC)
- Primary sclerosing cholangitis (PSC)
- HIV-associated sclerosing cholangitis: Associated with infection by CMV, *Cryptosporidium,* Microsporida, and *Mycobacterium avium* complex

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Biliary colic
- Acute cholecystitis
- Liver abscess
- Peptic ulcer disease (PUD)
- Pancreatitis
- Intestinal obstruction
- Right kidney stone
- Hepatitis
- Pyelonephritis

WORKUP

- Blood cultures
- CBC
- Liver function tests

LABORATORY TESTS

- Usually, elevated WBC count with a predominance of polymorphonuclear forms
- Elevated alkaline phosphatase and bilirubin in chronic obstruction
- Elevated transaminases in acute obstruction
- Positive blood cultures in 50% of cases, typically with enteric gram-negative aerobes (e.g., *Escherichia coli*, *Klebsiella pneumoniae*), enterococci, or anaerobes

IMAGING STUDIES

- Ultrasound:
  1. Allows visualization of the gallbladder and bile ducts to differentiate extrahepatic obstruction from intrahepatic cholestasis
  2. Insensitive but specific for visualization of common duct stones
- CT scan:
  1. Less accurate for gallstones
  2. More sensitive than ultrasound for visualization of the distal part of the common bile duct
  3. Also allows better definition of neoplasm
- ERCP:
  1. Confirms obstruction and its level
  2. Allows collection of specimens for culture and cytology
  3. Indicated for diagnosis if ultrasound and CT scan are inconclusive
  4. May be indicated in therapy (see "Treatment")

TREATMENT

NONPHARMACOLOGIC THERAPY

Biliary decompression:
- May be urgent in severely ill patients or those unresponsive to medical therapy within 12 to 24 hr
- May also be performed semielectively in patients who respond
- Options:
  1. ERCP with or without sphincterotomy or placement of a draining stent
  2. Percutaneous transhepatic biliary drainage for the acutely ill patient who is a poor surgical candidate
  3. Recently, endoscopic ultrasound–guided biliary drainage has been proven as an alternative to percutaneous transhepatic biliary drainage in specialized centers when ERCP fails or is not available
  4. Surgical exploration of the common bile duct

ACUTE GENERAL Rx

- Nothing by mouth
- Intravenous hydration
- Broad-spectrum antibiotics directed at gram-negative enteric organisms, anaerobes, and enterococcus such as carbapenems (meropenem: 1 g q8h or imipenem: 500 mg IV q6h if life threatening), piperacillin/tazobactam: 3.375 or 4.5 g IV q6h, or ampicillin-sulbactam, or ticarcillin-clavulanate; if infection is nosocomial, post-ERCP, or the patient is in shock, broaden antibiotic coverage
- Fig 1 illustrates a clinical algorithm for management of acute cholangitis

CHRONIC Rx

Repeated decompression may be necessary, particularly when obstruction is related to neoplasm.

DISPOSITION

Excellent prognosis if obstruction is amenable to definitive surgical therapy; otherwise relapses are common.

REFERRAL

- To biliary endoscopist if obstruction is from stones or a stent needs to be placed
- To interventional radiologist if external drainage is necessary
- To a general surgeon in all other cases
- To an infectious disease specialist if blood cultures are positive or the patient is in shock or otherwise severely ill

PEARLS & CONSIDERATIONS

- Cholangitis is a life-threatening form of intra-abdominal sepsis, though it may appear to be rather innocuous at its onset.
- Antibiotics alone will not resolve cholangitis in the presence of biliary obstruction, because high intrabiliary pressures prevent antibiotic delivery. Decompression and drainage of the biliary tract to alleviate the obstruction with antimicrobial therapy is the therapy of choice.

BASIC INFORMATION

DEFINITION

Cholecystitis is acute or chronic inflammation of the gallbladder generally caused by gallstones (>95% of cases).

SYNONYM

Gallbladder attack

ICD-10CM CODES	
K81.9	Acute cholecystitis
K80.00	Calculus of gallbladder with acute cholecystitis without obstruction
K81.9	Cholecystitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Acute cholecystitis occurs most commonly in women during the fifth and sixth decades. Approximately 120,000 cholecystectomies are performed for acute cholecystitis annually in the U.S.
- The incidence of gallstones is 0.6% in the general population and much higher in certain ethnic groups (>75% of Native Americans by age 60 yr). Most patients with gallstones are asymptomatic. Of such patients, biliary colic develops in 1% to 4% annually.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pain and tenderness in the right hypochondrium or epigastrium; pain possibly radiating to the infrascapular region
- Palpation of the right upper quadrant (RUQ) eliciting marked tenderness and stoppage of inspired breath (Murphy sign)
- Guarding
- Fever (33%)
- Jaundice (25% to 50% of patients)
- Palpable gallbladder (20% of cases)
- Nausea and vomiting (>70% of patients)
- Fever and chills (>25% of patients)
- Medical history often revealing ingestion of large, fatty meals before onset of pain in the epigastrium and RUQ

ETIOLOGY

- Gallstones (>95% of cases)
- Ischemic damage to the gallbladder, critically ill patient (acalculous cholecystitis)
- Infectious agents, especially in patients with AIDS (cytomegalovirus, Cryptosporidium)
- Strictures of the bile duct
- Neoplasms, primary or metastatic
- Risk factors for cholelithiasis include age, obesity, female sex, rapid weight loss, ethnicity/race (Native American), use of contraceptives, pregnancy, diabetes mellitus, hemolysis, total parenteral nutrition, biliary parasites

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hepatic: Hepatitis, abscess, hepatic congestion, neoplasm, trauma
- Biliary: Neoplasm, stricture, sphincter of Oddi dysfunction
- Gastric: Pelvic ulcer disease, neoplasm, alcoholic gastritis, hiatal hernia, non-ulcer dyspepsia
- Pancreatic: Pancreatitis, neoplasm, stone in the pancreatic duct or ampulla
- Renal: Calculi, infection, inflammation, neoplasm, ruptured kidney
- Pulmonary: Pneumonia, pulmonary infarction, right-sided pleurisy
- Intestinal: Retrocecal appendicitis, intestinal obstruction, high fecal impaction, irritable bowel syndrome (IBS), inflammatory bowel disease (IBD)
- Cardiac: Myocardial ischemia (particularly involving the inferior wall), pericarditis
- Cutaneous: Herpes zoster
- Trauma
- Fitz-Hugh–Curtis syndrome (perihepatitis), ruptured ectopic pregnancy
- Subphrenic abscess
- Dissecting aneurysm
- Nerve root irritation caused by osteoarthritis of the spine

WORKUP

Workup consists of detailed history and physical examination coupled with laboratory evaluation and imaging studies. No single clinical finding or laboratory test is sufficient to establish or exclude cholecystitis without further testing.

LABORATORY TESTS

- Leukocytosis (12,000 to 20,000) is present in >70% of patients.
- Elevated alkaline phosphatase, ALT, AST, bilirubin; bilirubin elevation >4 mg/dl is unusual and suggests presence of choledocholithiasis.
- Elevated amylase may be present (consider pancreatitis if serum amylase elevation exceeds 500 U).

IMAGING STUDIES

- Ultrasound of the gallbladder (Fig. E1) is the preferred initial test; it will demonstrate the presence of stones and also dilated gallbladder with thickened wall and surrounding edema in patients with acute cholecystitis.
- Nuclear imaging (HIDA scan) (Fig. E2) is useful for diagnosis of cholecystitis when sonogram is inconclusive: Sensitivity and specificity exceed 90% for acute cholecystitis. This test is only reliable when bilirubin is <5 mg/dl. A positive test result (absence of gallbladder filling within 60 min after the administration of tracer) will demonstrate obstruction of the cystic or common hepatic duct; the test will not demonstrate the presence of stones.
- CT scan of abdomen is useful in cases of suspected abscess, neoplasm, or pancreatitis.
- Plain radiograph of the abdomen generally is not useful because <25% of stones are radiopaque.

TREATMENT

NONPHARMACOLOGIC THERAPY

Provide IV hydration; withhold oral feedings.

ACUTE GENERAL Rx

- Laparoscopic (percutaneous) cholecystectomy (PC) is considered the treatment of choice for most patients. The rate of conversion to open cholecystectomy is higher when laparoscopic cholecystectomy (CCY) is performed for acute cholecystitis rather than for uncomplicated cholelithiasis; conservative management with IV fluids and antibiotics (ampicillin-sulbactam 3 g IV q6h or piperacillin-tazobactam 4.5 g IV q8h) may be justified in some high-risk patients to convert an emergency procedure into an elective one with a lower mortality rate.
- Endoscopic retrograde cholangiopancreatography with sphincterectomy and stone extraction can be performed in conjunction with laparoscopic cholecystectomy for patients with choledochal lithiasis; approximately 7% to 15% of patients with cholelithiasis also have stones in the common bile duct.

DISPOSITION

- Prognosis is good; elective laparoscopic cholecystectomy can be performed as outpatient procedure.
- Hospital stay (when necessary) varies from overnight with laparoscopic cholecystectomy to 4 to 7 days with open cholecystectomy.
- Complication rate is approximately 1% (hemorrhage and bile leak) for laparoscopic cholecystectomy and <0.5% (infection) with open cholecystectomy.

REFERRAL

Surgical referral in all patients with acute cholecystitis

PEARLS & CONSIDERATIONS

COMMENTS

- Patients should be instructed that stones may recur in bile ducts.
- Gallbladder aspiration, in which all fluid visualized by ultrasound is aspirated, represents a nonsurgical treatment when patients who are at high operative risk develop acute cholecystitis. Salvage cholecystectomy is reserved for nonresponders.

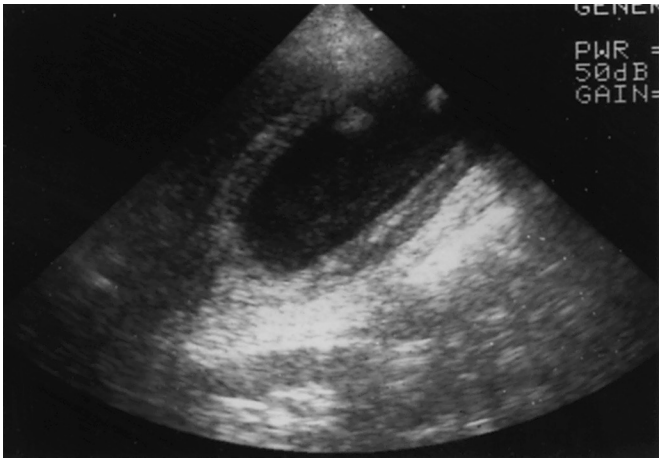

FIG. E1 Thickened gallbladder wall in acute cholecystitis. The gallbladder contains echogenic calculi. (From Grainger RG et al [eds]: *Grainger and Allison's diagnostic radiology,* ed 4, Philadelphia, 2001, Churchill Livingstone.)

FIG. E2 Acute cholecystitis. Following the intravenous administration of 200 MBq (5 mCi) of 99mTc-HIDA [technetium(99m)-hepatobiliary-iminodiacetic acid] and a stimulus of cholecystokinin (CCK), the region of the liver and gallbladder is imaged. Intrahepatic bile ducts are visualized, as is excretion through the common duct into the small bowel. The gallbladder is not seen. This patient had gallstones demonstrated by ultrasound and confirmed at surgery. The pathologic diagnosis was acute cholecystitis. (From Grainger RG et al [eds]: *Grainger and Allison's diagnostic radiology,* ed 4, Philadelphia, 2001, Churchill Livingstone.)

Choledocholithiasis

DEFINITION

Choledocholithiasis is a derivation from the Greek words of *choli* (bile), *docheion* (container), and *lithos* (stone) and refers to the presence of gallstones within the common bile duct (CBD).

SYNONYM

Common bile duct stone(s)

ICD-10CM CODE
K80.50 Calculus of bile duct

EPIDEMIOLOGY & DEMOGRAPHICS

- While the exact incidence and prevalence are unknown, an estimated 10% to 20% of patients are found to have choledocholithiasis at the time of cholecystectomy.
- Passage of gallstones into the CBD occurs in approximately 10% to 15% of those with cholelithiasis, and the incidence is known to increase with age. Approximately 95% of those with choledocholithiasis will also have cholelithiasis.
- Risk factors for gallstone formation include nonmodifiable factors such age, female sex, family history, ethnic background, and genetic predilection, while modifiable factors are centripetal obesity and metabolic syndrome, rapid weight loss, ileal Crohn disease, cirrhosis, total parenteral nutrition, and medications such as estrogen replacement therapy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Uncomplicated choledocholithiasis presents with biliary colic; it is classically described as intense and constant pain in the right upper quadrant or epigastric region, associated with nausea and vomiting.
- Occasionally patients may remain asymptomatic, but resolution of pain more often reflects passage of stone into the bowel.
- Physical examination demonstrates right upper quadrant or epigastric tenderness and occasionally jaundice.
- Courvoisier sign for a palpable gallbladder is more typically associated with malignant obstruction of the CBD, but it has been reported with choledocholithiasis.
- Other clinical findings of fever (Charcot triad), hypotension, and altered mental status (Reynolds pentad) are found only when choledocholithiasis is complicated by acute cholangitis.
- Choledocholithiasis can also be complicated by acute pancreatitis.

ETIOLOGY

- The majority of cases are due to passage of cholesterol stones from the gallbladder into the common bile duct.
- De novo formation of choledocholithiasis (primary choledocholithiasis) is uncommon but is seen among those with increased propensity for pigment stone formation due to chronic recurrent pyogenic cholangitis from trematodes, congenital biliary duct anomalies, dilated or strictured ducts or *MDR3* gene defects causing impairments in biliary phospholipid secretions, or biliary stasis such as from cystic fibrosis.
- Brown pigment stones comprise the majority of pigment stones in the bile duct, often found proximal to biliary stricture and associated with cholangitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Biliary pain
- Acute cholecystitis
- Sphincter of Oddi dysfunction
- Functional gallbladder disorder
- Malignant obstruction
- Choledochal cyst
- Papillary stenosis
- AIDS-associated cholangiopathy

WORKUP

- The constellation of symptomatic cholelithiasis with elevated liver enzymes should prompt a transabdominal ultrasound (US) of the right upper quadrant to evaluate for a stone in the CBD, which is the most reliable predictor of choledocholithiasis.
- Elevated liver enzymes are 94% sensitive in detecting choledocholithiasis.
- Clinical predictors should be utilized to risk-stratify patients and to inform the next step in management.
- High-risk predictors of choledocholithiasis:
  1. CBD stone seen on US or cross-sectional imaging
  2. Elevated serum bilirubin (>4 mg/dl) with evidence of dilated CBD on imaging
  3. Clinical or biochemical evidence of ascending cholangitis
- Intermediate-risk predictors of choledocholithiasis include abnormal liver biochemistries, age >55 yr and/or a dilated CBD seen on imaging.
- See Fig. 1 for a proposed risk stratification model based on American Society for Gastrointestinal Endoscopy guidelines.

LABORATORY TESTS

- Elevations in serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) reflect early biliary obstruction, followed by a disproportionate increase in serum bilirubin, alkaline phosphatase (ALP), and gamma-glutamyl transpeptidase (GGT), which are independent predictors of a CBD stone.
- Elevation in ALP is rapid and precedes the rise in bilirubin level, the latter being proportional to the degree of obstruction.
- An isolated and transient increase in alanine transaminase or amylase reflects passage of the gallstone.
- In addition, patients with choledocholithiasis complicated by acute pancreatitis and cholangitis have elevated serum amylase or lipase (>3 times upper limit of normal) and leukocytosis, respectively.

IMAGING STUDIES

- Ultrasound of the gallbladder has a relatively poor sensitivity (22% to 55%) for stone detection but is relied on for CBD dilation, which is associated with choledocholithiasis.
- The finding of CBD dilation >6 mm in patients with an intact gallbladder or >8 mm in patients with prior cholecystectomy is indicative of biliary obstruction. Multiple small gallbladder stones (<5 mm) portend a fourfold higher risk of passage of stones into the CBD.
- Other imaging modalities such as helical CT (Fig. 2), magnetic resonance cholangiopancreatography (MRCP), CT cholangiography, and endoscopic ultrasound (EUS) have improved performance characteristics for CBD stone detection; however, their use as first-line diagnostic tools is contingent on diagnostic uncertainty, patient factors, and availability.
- Either MRCP or EUS should be used in intermediate-risk patients to confirm the diagnosis of choledocholithiasis and prompt further therapeutic management.
- High-risk patients should proceed directly to endoscopic retrograde cholangiopancreatography (ERCP) for diagnosis and treatment.

TREATMENT

ACUTE GENERAL Rx

- Presence of choledocholithiasis warrants treatment.
- The mainstay is removal of CBD stones via ERCP and papillotomy either before or at the time of laparoscopic or open cholecystectomy.
- Failure of ERCP to clear the biliary duct warrants biliary stenting for drainage as a temporary measure in the event of acute cholangitis.
- Subsequent cholecystectomy should optimally be performed within 2 wk of pre-operative ERCP to reduce the risk of recurrence.
- ERCP without subsequent cholecystectomy may be performed in select high-risk patients, but 10% of these patients will require a subsequent cholecystectomy for recurrence.

CHRONIC Rx

Patients with recurrent choledocholithiasis from cholesterol gallstones after cholecystectomy might be considered for chronic treatment with ursodeoxycholic acid to facilitate reduction of cholesterol saturation of bile.

REFERRAL

- Gastroenterology
- General surgery

BASIC INFORMATION

DEFINITION

Cholelithiasis is the presence of stones in the gallbladder

SYNONYM

Gallstones

ICD-10CM CODES

K80.80	Other cholelithiasis without obstruction
K80.81	Other cholelithiasis with obstruction
K91.86	Retained cholelithiasis following cholecystectomy

EPIDEMIOLOGY & DEMOGRAPHICS

- Gallstone disease can be found in 12% of the U.S. population. Of these, 2% to 3% (500,000 to 600,000) are treated with cholecystectomies each yr.
- Annual medical expenditures for gallbladder surgeries in the U.S. exceed $5 billion.
- Incidence of gallbladder disease increases with age. Highest incidence is in the fifth and sixth decades. Predisposing factors for gallstones are female sex, pregnancy, age >40 yr, family history of gallstones, obesity, ileal disease, oral contraceptives, diabetes mellitus, rapid weight loss, estrogen replacement therapy.
- Patients with gallstones have a 20% chance of developing biliary colic or its complications at the end of a 20-yr period. Significant predictors of gallstone-related events are large stone (>10 mm), presence of multiple stones, and female sex.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination is entirely normal unless patient is having biliary colic; 80% of gallstones are asymptomatic.
- Typical symptoms of obstruction of the cystic duct include intermittent, severe, cramping pain affecting the right upper quadrant.
- Pain occurs mostly at night and may radiate to the back or right shoulder. It can last from a few minutes to several hours.
- Symptoms of gallstone disease and its complications are described in Table 1.

ETIOLOGY

- 75% of gallstones contain cholesterol and are usually associated with obesity, female sex, and diabetes mellitus; mixed stones are most common (80%); pure cholesterol stones account for only 10% of stones and are the result of biliary supersaturation due to cholesterol secretion into the gallbladder and accelerated cholesterol nucleation and crystallization.
- 25% of gallstones are pigment stones (bilirubin, calcium, and variable organic material) associated with hemolysis and cirrhosis. These tend to be black-pigmented stones that are refractory to medical therapy.
- 50% of mixed-type stones are radiopaque.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer disease
- Gastroesophageal reflux disease
- Irritable bowel disease
- Pancreatitis
- Neoplasms
- Nonnuclear dyspepsia
- Inferior wall myocardial infarction
- Hepatic abscess

LABORATORY TESTS

Generally normal unless patient has biliary obstruction (elevated alkaline phosphatase, bilirubin).

IMAGING STUDIES

- Ultrasound of the gallbladder (Fig. E1) will detect small stones and biliary sludge (sensitivity, 95%; specificity, 90%); the presence of dilated gallbladder with thickened wall is suggestive of acute cholecystitis.
- Nuclear imaging (HIDA scan) can confirm acute cholecystitis (>90% accuracy) if gallbladder does not visualize within 4 hr of injection and the radioisotope is excreted in the common bile duct.
- Common bile duct stones can be detected noninvasively by magnetic resonance cholangiopancreatography or invasively by endoscopic retrograde cholangiopancreatography (ERCP) and intraoperative cholangiography.

TREATMENT

NONPHARMACOLOGIC THERAPY

Lifestyle changes (avoidance of diets high in polyunsaturated fats, weight loss in obese patients; however, avoid rapid weight loss)

ACUTE GENERAL Rx

- The management of gallstones is affected by the clinical presentation.
- Asymptomatic patients do not require therapeutic intervention. Proposed criteria for prophylactic cholecystectomy are described in Table 2.
- Surgical intervention is generally the ideal approach for symptomatic patients. Laparoscopic cholecystectomy is preferred over open cholecystectomy because of the shorter recovery period and lower mortality

TABLE 1 Symptoms of Gallstone Disease and Its Complications

Disease	Pathophysiology	Symptoms
Biliary colic	Transient gallstone impaction at the cystic duct or ampulla of Vater	Intermittent RUQ pain associated with nausea or vomiting. Pain in the epigastrium or radiating to the right scapular tip. Episodes last 30 min to several hours with days or months between episodes.
Acute cholecystitis	Inflammation of the gallbladder caused by obstruction of the cystic duct. May occur in the presence or absence of bacterial superinfection	Patients appear ill and cannot take deep breaths. They have constant pain that lasts 30-60 min and worsens with movement. Persistent common bile duct impaction usually promotes vomiting. Physical examination demonstrates RUQ tenderness with voluntary guarding and a positive Murphy sign (arrest of inspiration during deep palpation over the gallbladder).
Emphysematous cholecystitis	Infection with gas-producing bacteria such as *Escherichia coli*, *Clostridium perfringens*, and anaerobic streptococci	Symptoms are similar to those with acute cholecystitis. Gas may be seen on abdominal plain films or CT. Male diabetics are most commonly affected.
Chronic cholecystitis	Persistent inflammation and fibrosis of the gallbladder with poor motor and absorptive function	Patients are usually asymptomatic but may report multiple previous attacks of colic. Porcelain gallbladder develops from chronic inflammation and may progress to carcinoma.
Acalculous cholecystitis	Probably related to biliary stasis in the setting of critical illness and altered gastrointestinal motility	Seen in patients with traumatic injuries, burns, and critical illness, as well as in those receiving total parenteral nutrition. The mortality for this disorder is twice as high as that for acute calculous cholecystitis.
Gallbladder perforation	Stones erode through an inflamed and necrotic gallbladder wall. Stones may travel into the peritoneal cavity or cause adhesions between nearby structures. Bile peritonitis may develop	More than half of patients with gallbladder perforation have fever and a palpable RUQ mass. Mortality in these patients is 30%.

CT, Computed tomography; *RUQ,* right upper quadrant.
From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.

rate. Between 5% and 26% of patients undergoing elective laparoscopic cholecystectomy will require conversion to an open procedure. Most common reason is the inability to clearly identify the biliary anatomy.

- Laparoscopic cholecystectomy after endoscopic sphincterectomy is recommended for patients with common bile duct stones and residual gallbladder stones. Where possible, single-stage laparoscopic treatments with removal of duct stones and cholecystectomy during the same procedure are preferable. Percutaneous cholecystectomy is an alternative for patients who are critically ill with gallbladder empyema and sepsis.
- Patients who are not appropriate candidates for surgery because of coexisting illness or patients who refuse surgery can be treated with oral bile salts: Ursodiol or chenodiol. Candidates for oral bile salts are patients with cholesterol stones (radiolucent, noncalcified stones), with a diameter of ≤15 mm and having three or fewer stones. Candidates for medical therapy must have a functioning gallbladder and must have absence of calcifications on CT scans.
- Extracorporeal shock wave lithotripsy (ESWL) is another form of medical therapy. It can be used in patients with stone diameter of ≤3 cm and having three or fewer stones.

TABLE 2 Proposed Criteria for Prophylactic Cholecystectomy

Life expectancy >20 yr
Calculi >2 cm in diameter
Calculi >3 mm and patent cystic duct
Radiopaque calculi
Gallbladder polyps >15 mm
Nonfunctioning or calcified gallbladder ("porcelain" gallbladder)
Women <60 yr
Patients in areas with high prevalence of gallbladder cancer

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

DISPOSITION

- Complicated gallstone events develop in 8% of patients with incidentally discovered gallstones after 17 yr (Shabanzadeh DM et al in Suggested Readings: *Gastroenterology* 150:156, 2016).
- After ESWL, stones recur in approximately 20% of patients after 4 yr.
- Patients with at least one gallstone <5 mm in diameter have a greater than fourfold increased risk of presenting with acute biliary pancreatitis. A policy of watchful waiting in such cases is generally warranted.
- A potential serious complication of gallstones is acute cholangitis. ERCP and endoscopic sphincterectomy followed by interval laparoscopic cholecystectomy are effective in acute cholangitis.
- Uncommon complications of gallstone disease are summarized in Table 3.

TABLE 3 Uncommon Complications of Gallstone Disease

Complication	Pathogenesis	Clinical Features	Diagnosis/Treatment
Emphysematous cholecystitis	Secondary infection of the gallbladder wall with gas-forming organisms (*Clostridium welchii, Escherichia coli*, and anaerobic streptococci) More common in older adult diabetic men; can occur without stones	Symptoms and signs similar to those of severe acute cholecystitis	Plain abdominal films may show gas in the gallbladder fossa US and CT are sensitive for confirming gas Treatment is with IV antibiotics, including anaerobic coverage, and early cholecystectomy High morbidity and mortality rates
Cholecystoenteric fistula	Erosion of a (usually large) stone through the gallbladder wall into the adjacent bowel, most often the duodenum, followed in frequency by the hepatic flexure, stomach, and jejunum	Symptoms and signs similar to those of acute cholecystitis, although sometimes a fistula may be clinically silent Stones >25 mm, especially in older adult women, may produce a bowel obstruction, or "gallstone ileus"; the terminal ileum is the most common site of obstruction Gastric outlet obstruction (Bouveret syndrome) may occur rarely	Plain abdominal films may show gas in the biliary tree and/or a small bowel obstruction in gallstone ileus, as well as a stone in the RLQ if the stone is calcified Contrast upper GI series may demonstrate the fistula A fistula from a solitary stone that passes may close spontaneously Cholecystectomy and bowel closure are curative Gallstone ileus requires emergency laparotomy; the diagnosis is often delayed, with a resulting mortality rate of ≈20%
Mirizzi syndrome	An impacted stone in the gallbladder neck or cystic duct, with extrinsic compression of the common hepatic duct from accompanying inflammation or fistula	Jaundice and RUQ pain	ERCP demonstrates dilated intrahepatic ducts and extrinsic compression of the common hepatic duct and possible fistula Preoperative diagnosis is important to guide surgery and minimize the risk of BD injury
Porcelain gallbladder	Intramural calcification of the gallbladder wall, usually in association with stones	No symptoms attributable to the calcified wall per se, but carcinoma of the gallbladder is a late complication in ≈20%	Plain abdominal films or CT show intramural calcification of the gallbladder wall Prophylactic cholecystectomy is indicated to prevent carcinoma

Cholera

BASIC INFORMATION

DEFINITION

Cholera is an acute diarrheal illness caused by toxin-producing strains of *Vibrio cholerae.*

ICD-10CM CODES

A00.0 Cholera due to Vibrio cholerae 01, biovar cholerae
A00.1 Cholera due to Vibrio cholerae 01, biovar eltor
A00.9 Cholera, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Extremely rare. Less than 25 cases have been reported in the United States since 2012.
- Average 6 cases/yr.
- Cholera is endemic in 60 countries. In the world, ~2.9 million cases and 100,000 deaths occur annually.
- Currently epidemic in Yemen due to war conditions.

PREDOMINANT SEX: None

PREDOMINANT AGE: In nonendemic areas, attack rates are equal in all age groups. In epidemic areas, children older than the age of 2 yr are most commonly infected. Neonatal infection: Illness is uncommon before the age of 2 yr, likely because of passive immunity.

PEAK INCIDENCE:

- None in the U.S.
- Summer and fall in endemic areas (Africa, South and Southeast Asia) (before and after rainy season)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Infection may result in asymptomatic illness or a mild diarrhea. The classic illness is described as the abrupt onset of voluminous watery diarrhea, which may lead to severe dehydration, acidosis, shock, and death. Vomiting may occur early in the illness, but fever and abdominal pain are usually absent. The typical "rice water" stools are pale with flecks of mucus and contain no blood. Muscle cramps may be prominent and are the result of loss of fluid and electrolytes. Untreated illness results in hypovolemic shock, and death may occur in hours to days. With adequate fluid and electrolyte repletion, cholera is a self-limited illness that resolves in a few days. The use of antimicrobials can shorten the course of illness.

ETIOLOGY

The organism responsible for this illness is one of several strains of *V. cholerae.* Most infections result from the O1 serotype, the El Tor biotype. In the U.S., one outbreak occurred from the ingestion of illegally imported crab, and sporadic infection has been associated with the consumption of contaminated shellfish in Gulf Coast states. Most cases are seen in returning travelers. Transmission during epidemics is the result of the ingestion of contaminated water and, in some instances, contaminated food. Person-to-person transmission is common in epidemics.

An important outbreak of cholera followed the 2010 earthquake in Haiti, with many cases also in the Dominican Republic (which shares the island of Hispaniola with Haiti). Subsequently, cholera was detected in Cuba, Venezuela, and Florida in travelers from Hispaniola. Interestingly, the strain of cholera was related to the strains of Southeast Asia rather than South America and was possibly introduced by UN peacekeepers from Nepal.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mild illness may mimic gastroenteritis resulting from a variety of etiologies.
- Sudden, voluminous diarrhea causing marked dehydration is uncommon in other illnesses.

WORKUP

Stool should be sent for culture and microscopy. Treatment should not be delayed while awaiting culture results.

LABORATORY TESTS

- WBC may be elevated, and hemoglobin may be increased as a result of hemoconcentration.
- Elevated blood urea nitrogen (BUN) and creatinine suggests prerenal azotemia. Hypoglycemia may occur. Stool cultures on appropriate media may grow the organism.
- Wet mount of stool under dark field or phase contrast microscopy shows organisms with characteristic darting motility.
- Dipstick tests such as Crystal VC are now available to test for O1 or O139 antigens.

TREATMENT

NONPHARMACOLOGIC THERAPY

The mainstay of therapy is adequate fluid and electrolyte replacement (Table E1). This can usually be achieved using oral rehydration solutions containing salts and glucose. Some patients may require intravenous fluid and electrolyte replacement.

ACUTE GENERAL Rx

- Antimicrobial therapy (Table E2) can decrease shedding of fluid and organisms and can shorten the course of illness:
  1. Doxycycline 300 mg PO single dose *or*
  2. Azithromycin two 500-mg tablets PO as a single dose *or*
  3. Tetracycline 500 mg PO qid × 3 days *or*
  4. Erythromycin 500 mg qid × 3 days
  5. Ciprofloxacin 1 g as a single dose
- For pregnant women: Azithromycin 1 g PO single dose.
- For children: Azithromycin 20 mg/kg PO as a single dose.
- Resistance to sulfamethoxazole and trimethoprim (SMX-TMP) is increasing in travel-associated infections, so SMX-TMP is no longer recommended.
- Zinc and vitamin A supplementation may be helpful in children.
- Susceptibility testing is often available to tailor the choice of antibiotic.

CHRONIC Rx

It is likely that asymptomatic chronic carriers exist; however, because they are difficult to identify and their role in transmission of disease appears to be rather limited, there is no recommendation for treatment of these individuals.

DISPOSITION

The mortality rate of adequately hydrated patients is less than 1%.

REFERRAL

If more than mild illness occurs

REPORTING

In the U.S., all cases of cholera must be reported to the local and state health departments. Bacterial isolates must be sent to the state health department and the CDC.

TABLE E1 Electrolyte Concentration in Cholera Stool and in Fluids Used for Rehydration and Replacement of Stool Losses

	Electrolyte Concentration (mmol/L)				
	Na^+	Cl^-	K^+	HCO_3^-	Osmolality
Cholera Stool					
Adults	130	100	20	44	300[a]
Infants and children	100	90	33	30	300[a]
Hydration Solutions					
WHO oral rehydration	75	65	20	10[b]	170[c]
Intravenous					
Dhaka	133	98	13	48	273
Lactated Ringer solution	130	109	4	28[d]	251
5:4:1[e]	129	97	11	44	281

WHO, World Health Organization.
[a]Osmolality includes unmeasured osmotically active molecules (primarily organic acids) in addition to electrolytes.
[b]As citrate.
[c]From electrolytes only; also contains 75 mmol/L of glucose.
[d]As lactate.
[e]Intravenous solution containing 5 g sodium chloride, 4 g sodium bicarbonate, and 1 g potassium chloride per liter.
(From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.)

TABLE E2 Antimicrobial Therapy of Cholera[a]

Agent	Single Dose	Multiple Dose
Azithromycin	20 mg/kg; maximal dose 1 g	
Erythromycin	Not evaluated	50 mg/kg/day erythromycin divided into 4 doses for 3 days; maximal dose 2 g/day
Doxycycline	2-4 mg/kg; maximal dose 300 mg	
Tetracycline	Not evaluated	50 mg/kg/day divided into 4 doses for 3 days; maximal dose 2 g/day
Ciprofloxacin[b]	20 mg/kg; maximal dose 1 g	30 mg/kg/day divided into 2 doses for 3 days; maximal dose 1 g/day
Trimethoprim-sulfamethoxazole	Not evaluated	10 mg trimethoprim/50 mg sulfamethoxazole/kg/day divided into 2 doses for 5 days; maximal doses 320 mg trimethoprim and 1.6 g sulfamethoxazole daily
Ampicillin	Not evaluated	50 mg/kg/day divided into 4 doses for 3 days; maximal dose 2 g/day
Furazolidone	7 mg/kg; maximal dose 300 mg[c]	5 mg/kg/day divided into 4 doses for 3 days; maximal dose 400 mg/day

Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

[a]Antimicrobial therapy is an adjunct to fluid therapy for cholera and is not an essential component. It reduces diarrhea volume and duration, however, by approximately 50%. The choice of antimicrobial agent is determined by the susceptibility pattern of local strains of Vibrio cholerae O1 or O139. Resistance to all agents has been reported and is common in some areas.

[b]The fluoroquinolones, such as ciprofloxacin, are only approved for use in children younger than 18 yr in the United States for special indications because of concerns about arthropathy; multidose therapy has not been evaluated systematically in children, and recommendations are extrapolated from experience in adults.

[c]Single-dose therapy with these drugs has not been evaluated systematically in children, and recommendations are extrapolated from experience in adults.

PREVENTION

- A killed oral cholera vaccine (Stanchol) has been available for prevention of cholera outside the U.S. It is administered in a two-dose schedule. However, a recent trial revealed that a single dose of Stanchol was efficacious in older children (≥5 yr of age) and in adults in a setting with a high level of cholera endemicity.
- In 2016 the FDA approved Vaxchora (PaxVax, Inc., Redwood City, CA), a single-dose, oral, live-attenuated cholera vaccine, for protection against *Vibrio cholerae* serogroup 01 in adults 18 to 64 yr old traveling to endemic or epidemic areas who are at high risk of exposure. The vaccine is administered as a single dose at least 10 days before potential exposure. Cost for one dose is $200 to $250. The vaccine should not be given to patients who have taken oral or parenteral antibiotics in the previous 2 wk.

PEARLS & CONSIDERATIONS

COMMENTS

- Vaccination now recommended.
- Recent guidelines from the Advisory Committee for Immunization Practices (ACIP) were published in the May 12, 2017, Morbidity and Mortality Weekly Report (MMWR).
- Lyophilized CVD 103-HgR is now recommended for adults (ages 18 to 64) traveling to areas with endemic or epidemic cholera caused by *V. cholerae* O1.
- Brand name is Vaxchora.

SUMMARY OF FINDINGS

- This is the only vaccine licensed for use in the U.S.
- This is a LIVE, oral, single-dose vaccine.
- Efficacy against severe diarrhea is 90% at 10 days after vaccination, falling to 80% at 3 mo.
- No serious adverse events have been reported.
- The vaccine strain may be shed in the stool for 7 days or more.
- The vaccine is not routinely recommended for travelers who are not visiting areas of active cholera transmission.
- No data currently exists on the safety and effectiveness of lyophilized CVD 103-HgR vaccine in children and teens aged <18 yr or adults aged ≥65 yr and use of vaccine in immunocompromised persons and pregnant and breastfeeding women.

BASIC INFORMATION

DEFINITION

Chorea is the term used to describe brief movements that involve contiguous muscle groups. The term comes from the Greek word meaning *dance*.

SYNONYMS

Sydenham chorea
Saint Vitus dance

ICD-10CM CODES

G25.4	Drug-induced chorea
G25.5	Other chorea
I02.0	Rheumatic chorea with heart involvement
I02.9	Rheumatic chorea without heart involvement

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: No published data exist on the incidence of chorea in the U.S.
PREDOMINANT SEX AND AGE: Can affect any age and sex depending on the cause
RISK FACTORS: The most important risk factors are a family history of Huntington disease, exposure to rheumatic fever as a child, or being pregnant with a history of rheumatic fever.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Presentation depends on the underlying cause. Huntington disease (HD) (Fig. E1 and Fig. E2) typically presents with neuropsychiatric symptoms predating choreiform movements. In the case of Sydenham chorea, drug-induced chorea, or chorea gravidarum, hyperkinetic movements involving the hands and face may be noticed first. Nonrhythmic, random, brief, contiguous movement and facial grimacing can be clues to the presence of chorea. Writhing movement of the hands or feet is known as *athetosis*. An enlarged tongue and self-mutilation may accompany chorea in patients with neuroacanthocytosis. Choreiform movements tend to be suppressed during physical examination; look for suppressive techniques such as holding of the face or crossing of the legs.

Chorea involving specific body parts can be a clue to the proper differential diagnosis. For example, chorea involving the forehead muscles is seen in HD. These muscles typically are spared in tardive dyskinesia. Orobuccolingual chorea is seen in tardive dyskinesia, acquired hepatocerebral degeneration, and neuroacanthocytosis. Hemichorea/hemibalism can be seen arising in nonketotic hyperglycemia, polycythemia vera, Sydenham chorea, antiphospholid antibody syndrome, and structural lesions (such as ischemic strokes) affecting the contralateral thalamus or subthalamic nucleus, basal ganglia, or even corona radiata.

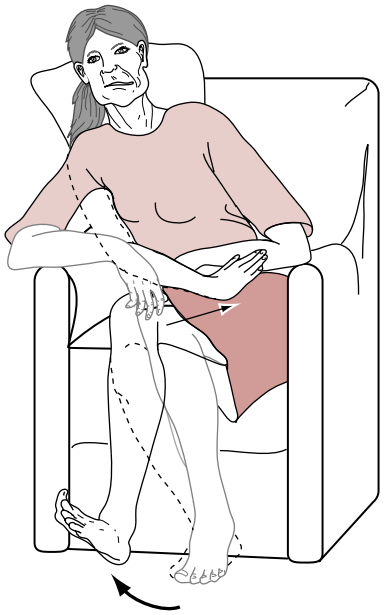

FIG. E1 As in this woman with Huntington disease, chorea consists of intermittent, random involuntary movements, such as brisk contractions in pelvic, trunk, and limb muscles. It also encompasses a mere flick of a finger or wrist, forward jutting of the leg, or shrugging of the shoulder. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

ETIOLOGY

- The most common genetic causes of chorea (Table E1) include benign hereditary chorea, Huntington disease, C9orf72 hexanucleotide repeat expansion (first described in families with frontotemporal dementia and ALS but then discovered to have an expanded phenotype include an HD phenocopy in those of European origin), and spinocerebellar ataxia type 17. Other genetic causes are neuroacanthocytosis, dentatorubral-pallidoluysian atrophy (DRPLA), neurodegeneration with brain iron accumulation, and Wilson disease.
- Infectious causes include rheumatic fever causing Sydenham chorea (most common cause of chorea in children), toxoplasmosis of the basal ganglia, and prion disease.
- Drug-induced causes include cocaine, amphetamine, oral contraceptives, tricyclic antidepressants, cimetidine, digoxin, verapamil, baclofen, steroids, antiepileptics, and neuroleptics. Tardive dyskinesia, most typically from dopamine-blocking agents such as neuroleptics or some antiemetics, can result in choreiform movements.
- Hemichorea may be due to antiphospholipid antibody syndrome, systemic lupus erythematosus, or hemichorea-hemiballismus syndrome due to severe nonketotic hyperglycemia, polycythemia vera, or contralateral structural lesion, such as ischemic stroke of the basal ganglia, thalamus, or subthalamic nucleus.
- Acquired causes of chorea are summarized in Table E2.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Huntington disease
- Tardive dyskinesia
- Dystonia
- Tic disorders
- Stroke
- Prion disease
- Rheumatic fever
- Conversion disorder

LABORATORY TESTS

- Complete metabolic panel, including liver function tests
- CBC with peripheral smear looking for acanthocytes
- Serum copper and ceruloplasmin levels
- Thyroid function tests
- Antistreptolysin O antibodies
- Genetic testing for Huntington disease should be done at a comprehensive center involving neurology, psychology, and genetics; complete team support is required before genetic testing is undertaken.

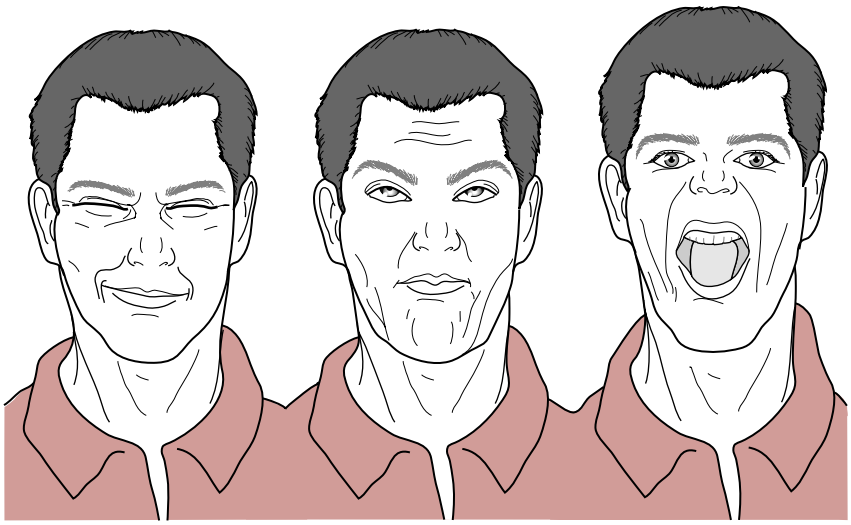

FIG. E2 Huntington disease patients characteristically make unexpected, inappropriate, and incomplete facial expressions. Without provocation, they frown, raise eyebrows, and smirk. Because the tongue frequently protrudes, this chorea occasionally mimics tardive dyskinesia. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

TABLE E1 Inherited Causes of Childhood-Onset Chorea

Disease Name	Inheritance	Associated Gene	Age Of Onset	Neurologic Or Psychiatric Manifestations	Systemic Symptoms
Chorea Prominent Feature					
Ataxia- telangiectasia	AR	*ATM*	18 mo-3 yr	Chorea often initial symptom; also have oculomotor apraxia, ataxia, and dystonia	Telangiectasias, increased sinopulmonary infections, increased incidence of cancer
Ataxia with oculomotor apraxia 1 and 2 (especially type 1)	AR	*APTX*	Onset later than ataxia-telangiectasia	Chorea, dystonia, oculomotor apraxia, ataxia, distal sensory axonal neuropathy	
Friedreich ataxia	AR	GAAn in *FRDA*	Over 2 yr, usually teenagers	Gait ataxia, axonal neuropathy, areflexia, extensor plantar response. Can have various movements (tremor, dystonia, chorea, myoclonus). Cases of chorea without cerebellar signs described	Cardiomyopathy, diabetes
GNAO1-related dyskinesias	AR	*GNAO1*	Infancy	Ballismus, chorea, orofacial dyskinesias; can alternatively cause Ohtahara syndrome	
Benign hereditary chorea	AD	*NKX2-1*	Prior to age 5 yr	Chorea; can have myoclonus, learning disability	Thyroid disease, lung disease
Benign hereditary chorea with or without facial "myokymia"	AD	ADCY5	Infancy to late adolescence	Chorea, choreic facial twitches (previously called myokymia); can have myoclonus or dystonia	Some reports of congestive heart failure
PDE10A-associated chorea	AD or AR	*PDE10A*	AD: Childhood AR: Infancy	Chorea, MRI striatal changes in AD form	
Paroxysmal nonkinesigenic dyskinesias	AD	*MR1*	Infancy to 10 yr	Dystonia, chorea, or a combination	
3-methylglutaconic aciduria type III (Costeff syndrome)	AR	*OPA3*	Infancy	Bilateral optic atrophy and chorea early; spasticity, ataxia, and dementia later	
Congenital cataracts, facial dysmorphism, and neuropathy	AR	*CTDP1*	Infancy or childhood	Progressive neuropathy, delayed psychomotor development, mild chorea, hypomyelination, hearing loss	Skeletal abnormalities, dysmorphic face, congenital cataracts, microcornea, hypogonadism
Dentatorubral-pallidoluysian atrophy	AD	CAGn in *atrophin-1*	Mostly adults but seen in a few children	Neurodegeneration, chorea, tics, dementia, seizures, ataxia, psychiatric symptoms	
Huntington chorea/ disease	AD	CAGn in *HTT*	Adolescence to 40s	Younger onset *without* chorea and with parkinsonism, but later, teenagers can manifest chorea, emotional disturbances similar to adult form	
Huntington disease-like-3 (HDL3)	AR	Linked to chromosome 4p15.3	Childhood	Neurodegeneration, chorea, dystonia, ataxia, dementia, seizures	
Idiopathic basal ganglia calcification (IBGC), childhood onset (bilateral striopallidodentate calcinosis)	AR or AD	*SLC20A2* or *PDGFRB*	Infancy to second decade of life	Tetraplegia, chorea, severe cognitive impairment, microcephaly, basal ganglia calcifications	Early death
Choreoacanthocytosis	AR	*VPS13A*	Mean age 20 yr but described in childhood	Psychiatric symptoms (e.g., obsessive-compulsive disorder) can precede neurologic symptoms Neurodegeneration, progressive hyperkinetic movements (limb chorea, orofacial dyskinesias, tics, dystonia), dementia, seizures, cognitive decline, sensorimotor polyneuropathy	Acanthocytosis, increased CK and/or liver transaminases
Spinocerebellar ataxia 1	AD	CAGn in *ATXN1*	Childhood	Neurodegeneration, progressive ataxia, mild cognitive impairment, dysarthria, ophthalmoplegia, optic atrophy, spasticity, dystonia or chorea	

TABLE E1 Inherited Causes of Childhood-Onset Chorea—cont'd

Disease Name	Inheritance	Associated Gene	Age Of Onset	Neurologic Or Psychiatric Manifestations	Systemic Symptoms
Spinocerebellar ataxia 17	AD	CAGn or CAAn in *TBP*	Mostly early adulthood but some teenagers reported	Neurodegeneration, psychiatric symptoms (depression, hallucinations), frontal release signs, chorea, dystonia, and parkinsonism; may have ocular movement abnormalities	
Leigh syndrome	X-linked	*PDHA1*	Infancy or childhood	Neurodegeneration, psychomotor delay, hypotonia and chorea and other hyperkinetic movements can be prominent, progresses to feeding and swallowing defects, nystagmus, ophthalmoplegia, optic atrophy, seizures Lesions in basal ganglia, cerebrum, cerebellum, spinal cord	Lactic acidemia, respiratory failure
Nonketotic hyperglycemia (glycine encephalopathy)	AR	*GLDC, GCST,* or *GCSH*	Neonates/infancy	Hypotonia, severe myoclonic epilepsy, profound cognitive impairment, restlessness	Hyperglycemia
Infantile bilateral striatal necrosis	AR	*NUP62*	Infancy	Developmental regression, intellectual disability, pendular nystagmus, optic atrophy, dysphagia, dystonia, choreoathetosis, spasticity, and severe bilateral striatal atrophy	
Chorea Sometimes Present					
Spinocerebellar ataxia 7	AD	CAGn in *ATXN7*	Childhood	Neurodegenerative mitochondrial disorder, progressive ataxia, dysarthria, dysphagia, optic atrophy, ophthalmoplegia, spasticity, dystonia or chorea may occur	Retinal degeneration
Wilson disease	AR	*ATP7B*	12 yr to early 20s	Dysarthria, drooling, pharyngeal dysmotility, clumsiness, tremor ("wing-beating"), psychiatric symptoms (decline in school, anxiety, depression, psychosis); chorea and dystonia variable	Hepatic dysfunction (asymmetric hepatomegaly, acute transient or fulminant hepatitis), Kayser-Fleischer rings of cornea
Lesch-Nyhan disease	X-linked	*HPRT*	Early childhood	Self-injurious behaviors, intellectual disability, motor disability, pyramidal signs, dystonia superimposed on hypotonia, may have chorea or ballismus, abnormal ocular motility	Hyperuricemia, nephrolithiasis, gout
Pantothenate kinase–associated neurodegeneration (PKAN), classic form	AR	*PANK2*	Prior to 6 yr old (in classic onset)	Progressive motor difficulties, personality changes, cognitive decline, dysarthria, spasticity; later onset of movements (dystonia most common, chorea or tremor may also be present); "eye of the tiger" sign on MRI of brain	Pigmentary retinal degeneration, acanthocytosis
Paroxysmal kinesigenic dyskinesia (PKD)	AD	*PRRT2*	1-20 yr	Short episodes triggered by sudden movement; dystonia is most common movement but can have chorea	
Biopterin-dependent hyperphenylalaninemia (group of disorders)	Usually AR	Multiple genetic causes	Neonate	Initially hypotonic with poor suck, decreased movements, and microcephaly; months later, oculogyric crises, swallowing difficulties, variable hypo- and hyperkinetic movements, seizures, cognitive impairment	Elevated phenylalanine level at birth Autonomic symptoms start several months later
Glutaric aciduria	AR	*GCDH*	First 6 mo	Hypotonia and jitteriness at birth; at 6-18 mo, progressive hyperkinetic movements (dystonia, choreoathetosis); may have seizures	

Continued

TABLE E1 Inherited Causes of Childhood-Onset Chorea—cont'd

Disease Name	Inheritance	Associated Gene	Age Of Onset	Neurologic Or Psychiatric Manifestations	Systemic Symptoms
Alternating hemiplegia of childhood	AR	*ATP1A-3*	Neonate to <18 mo	Transient episodes of alternating hemiplegia/hemiparesis, dystonic attacks, paroxysmal abnormal ocular movements, seizures, episodes of autonomic dysfunction; between attacks, may have ataxia, dystonia, and/or choreoathetosis; most have intellectual disability	
Succinate semialdehyde dehydrogenase deficiency	AR	*ALDH5A*	Infancy to early childhood	Intellectual disability, pronounced language dysfunction, autistic traits, hypotonia, aggression, ataxia, anxiety, hallucinations, can have choreoathetosis	

AD, Autosomal dominant; *AR*, autosomal recessive; *CK*, creatine kinase.
From Kliegman RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

TABLE E2 Acquired Causes of Chorea

Structural-Basal Ganglia Lesions

Stroke
Moyamoya disease
Vascular malformations
Hemorrhage
Choreoathetoid cerebral palsy
Postcardiac transplant (postpump chorea)
Mass lesions (CNS lymphoma, metastatic brain tumors)
Multiple sclerosis plaque
Extrapontine myelinolysis
Trauma

Parainfectious And Autoimmune Disorders

Poststreptococcal Sydenham chorea
Chorea secondary to systemic lupus erythematosus
Chorea secondary to antiphospholipid antibody syndrome
Acute disseminated encephalomyelitis
Anti-NMDA receptor encephalitis
Rasmussen encephalitis
Chorea gravidarum
Postinfectious or postvaccinal encephalitis
Paraneoplastic choreas

Infectious Disorders

HIV encephalopathy
Toxoplasmosis
Cysticercosis
Diphtheria
Bacterial endocarditis
Neurosyphilis
Scarlet fever
Viral encephalitis (mumps, measles, varicella)

Metabolic Or Toxic Disorders

Acute intermittent porphyria
Hyponatremia/hypernatremia
Hypocalcemia
Hyperthyroidism
Hypoparathyroidism
Hepatic/renal failure
Carbon monoxide poisoning
Methyl alcohol
Toluene
Manganese poisoning
Mercury poisoning
Organophosphate poisoning
Pheochromocytoma

Psychogenic Disorders

Drug-Induced Disorders

Dopamine-Blocking Agents (upon withdrawal or as a tardive syndrome)	Phenothiazines Butyrophenones Benzamides
Antiparkinsonian Drugs	L-DOPA Dopamine agonists Anticholinergics
Antiepileptic Drugs	Phenytoin Carbamazepine Valproic acid
Psychostimulants	Amphetamines Methylphenidate Cocaine
Calcium Channel Blockers	Cinnarizine Flunarizine Verapamil
Others	Lithium Baclofen Digoxin Tricyclic antidepressants Cyclosporine Steroids/oral contraceptives Theophylline Propofol

L-DOPA, Levodopa; *NMDA*, N-methyl-D-aspartate.
From Kliegman RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

IMAGING STUDIES

- MRI of the brain with and without contrast
- Echocardiogram if rheumatic fever is suspected

Rx TREATMENT

- Depending on the cause, treatment must be tailored.
- Chorea related to Huntington disease can be treated with tetrabenazine or deutetrabenazine (recently approved by the FDA). Caution must be exercised because the medication puts the patient at significant risk for depression.
- Withdrawing the offending drug can treat drug-induced chorea.
- Some conditions such as SCA3 or neuroacanthocytosis and Huntington disease have a strong neuropsychiatric component and may need to be comanaged with behavioral health specialists.

NONPHARMACOLOGIC THERAPY

- Rehabilitative services such as physical therapy, occupational therapy, and speech therapy are important for genetic forms of chorea.
- Cognitive therapy is now becoming more important in maintaining quality of life in most of these disorders.

ACUTE GENERAL Rx

- Sudden-onset chorea warrants brain imaging to evaluate for stroke.
- MRI of the brain is important for full evaluation of chorea, as it allows for the evaluation of basal ganglia structure. Huntington disease is associated with atrophy of the head of the caudate.
- Subacute onset chorea may represent autoimmune or paraneoplastic syndromes due to a host of autoantibodies including anti-NMDA, anti-Hu, and anti-CRMP-5, anti-Yo, anti-LGI1, anti-CASPR2, anti-GAD65, and anti-IgLON5.

CHRONIC Rx

- Tetrabenazine and deutetrabenazine are the only medications currently approved by the FDA to treat the chorea of Huntington disease. These medications reduce the chorea but do not halt the underlying neurodegenerative process of Huntington disease.
- Deutetrabenazine and valbenazine are the only medications currently approved by the FDA for treating tardive dyskinesia.
- A multidisciplinary approach is useful for treating Huntington disease.

COMPLEMENTARY MEDICINE

There are case reports showing some efficacy in acupuncture for the treatment of temporomandibular chorea in a patient with Sydenham chorea.

DISPOSITION

- Sydenham chorea and chorea gravidarum tend to resolve in a few weeks.
- Huntington disease is a progressive neurodegenerative disorder.
- Tardive dyskinesia due to neuroleptics may be treated medically, and offending agents should be withdrawn, but comanagement with a psychiatrist is imperative to avoid destabilization of the patient and to monitor for depression using TD-specific therapy.

REFERRAL

Refer to a neurologist.

PEARLS & CONSIDERATIONS

COMMENTS

Chorea is a symptom of an underlying disorder. Investigations are targeted to identify reversible causes.

PREVENTION

- Treat streptococcal throat infection early to prevent future complications.
- Weigh risk-benefit in using medications known to cause tardive dyskinesia.

PATIENT & FAMILY EDUCATION

For Huntington disease and other genetic forms of chorea, it is important to provide support and refer to support groups.

Chronic Fatigue Syndrome PTG ALG

BASIC INFORMATION

DEFINITION

Chronic fatigue syndrome (CFS), also known as myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS) and systemic exertion intolerance disease (SEID), is characterized by at least three of the following symptoms, present concurrently for at least 6 mo:

- Impaired memory or concentration (cognitive impairment)
- Sore throat
- Tender cervical or axillary lymph nodes
- Muscle pain
- Multijoint pain
- New headaches
- Unrefreshing sleep
- Postexertion malaise for longer than 24 hr
- Orthostatic intolerance

There are currently several sets of clinical criteria to define ME/CFS, yet there is no consensus regarding which set of criteria best identifies patients with this condition. In 2015, the Institute of Medicine (IOM) recommended renaming ME/CSF "systemic exertion intolerance disease (SEID)." Their definition requires that patients have: 1. Substantial reduction or impairment in the ability to engage in premorbid levels of activities persisting for >6 mo and associated with new-onset fatigue not alleviated by rest; 2. Postexertional fatigue; 3. Unrefreshing sleep; and 4. Presence of cognitive impairment and/or orthostatic intolerance.

SYNONYMS

Systemic exertion intolerance disease (SEID)
Yuppie flu
CFS
Chronic Epstein-Barr syndrome
Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS)
Neurasthenia

ICD-10CM CODES

R53.82 Chronic fatigue, unspecified
F45.8 Other somatoform disorders

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE IN U.S.: Prevalence rates of CFS in the U.S. range from 0.3% to 2.5%. It is estimated that 800,000 to 2.5 million Americans have CFS

PREDOMINANT AGE: Young adulthood and middle age

PREDOMINANT SEX: Females affected more often than males

ECONOMICS: The estimated annual cost of lost productivity is estimated to be between $17 billion and $24 billion annually

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- There are no physical findings specific for CFS.
- The physical examination may be useful to identify fibromyalgia and other rheumatologic conditions that may coexist with CFS.

ETIOLOGY

- The etiology of CFS is unknown. The pathophysiologic dysregulation of the thalamus, hypothalamus, and amygdala is believed by some to be a potential cause of SEID.
- Some theorize that a viral illness may trigger certain immune responses that lead to the various symptoms. Most patients often report the onset of their symptoms with a flulike illness.
- The presence of numerous psychiatric comorbidities in CFS have led some experts to question the existence of any organic etiology.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Psychosocial depression, dysthymia, anxiety-related disorders, and other psychiatric diseases
- Sleep apnea
- Infectious diseases (subacute bacterial endocarditis, Lyme disease, fungal diseases, mononucleosis, HIV, chronic hepatitis B or C, tuberculosis [TB], chronic parasitic infections)
- Autoimmune diseases: Systemic lupus erythematosus, myasthenia gravis, multiple sclerosis, thyroiditis, rheumatoid arthritis
- Endocrine abnormalities: Hypothyroidism, hypopituitarism, adrenal insufficiency, Cushing syndrome, diabetes mellitus, hyperparathyroidism, pregnancy, reactive hypoglycemia
- Occult malignant disease
- Substance abuse
- Systemic disorders: Chronic renal failure, chronic obstructive pulmonary disease, cardiovascular disease, anemia, electrolyte abnormalities, liver disease
- Other: Inadequate rest, sleep apnea, narcolepsy, fibromyalgia, sarcoidosis, medications, toxic agent exposure, Wegener granulomatosis, vitamin deficiency

LABORATORY TESTS

- No specific laboratory tests exist for diagnosing CFS. Initial laboratory tests are useful to exclude other conditions that may mimic or may be associated with CFS.
  1. Screening laboratory tests: CBC, ESR, ALT, total protein, albumin, globulin, alkaline phosphatase, calcium, phosphorus, glucose, BUN, creatinine, electrolytes, TSH, and urinalysis are useful.
  2. Serologic tests for Epstein-Barr virus, *Candida albicans,* human herpesvirus 6, and other studies for immune cellular abnormalities are not useful; these tests are expensive and generally not recommended.
- Other tests may be indicated depending on the history and physical examination (e.g., ANA, RF in patients presenting with joint complaints or abnormalities on physical examination, Lyme titer in areas where Lyme disease is endemic).

IMAGING STUDIES

Generally not recommended unless history and physical examination indicate specific abnormalities (e.g., chest radiography in any patient suspected of TB or sarcoidosis)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Patients should be reassured that the illness is not fatal and that most patients improve over time.
- An initially supervised exercise program to preserve and increase strength is beneficial for most patients and can improve symptoms.
- Cognitive-behavioral therapy trials have shown positive effects on fatigue levels, work, depression/anxiety, and social adjustment.

GENERAL Rx

Therapy is generally palliative. The following medications may be helpful; however, evidence is conflicting:

- Antidepressants: The choice of antidepressant varies with the desired side effects. Patients with difficulty sleeping or fibromyalgia-like symptoms may benefit from low-dose trazodone 50 mg hs. When sedation is not desirable, low-dose SSRIs (fluoxetine 20 mg qd) often help alleviate fatigue and associated symptoms.
- NSAIDs can be used to relieve muscle and joint pain and headaches.
- "Alternative" medications (herbs, multivitamins, nutritional supplements) are very popular with many CFS patients but are generally not very helpful.
- B-lymphocyte depletion using rituximab has failed to show any benefit in trials.

PEARLS & CONSIDERATIONS

COMMENTS

- In CFS the symptoms are serious enough to reduce daily activities by >50% in the absence of any other medically identifiable disorders.
- The suicide rate is nearly sevenfold higher in people with CFS.
- Moderate to complete recovery at 1 yr occurs in 22% to 60% of patients with CFS.
- Early trials using an electrical impedance assay have shown promise in identifying CFS patients.

Chronic Inflammatory Demyelinating Polyneuropathy

BASIC INFORMATION

DEFINITION

Chronic inflammatory demyelinating polyneuropathy (CIDP) is a chronic autoimmune neuropathy manifesting with symmetric proximal and distal weakness with associated sensory loss along with reduced or absent reflexes. By definition, the symptoms reach nadir no earlier than 8 wk after onset.

SYNONYMS

Chronic inflammatory demyelinating polyradiculoneuropathy
CIDP

ICD-10CM CODE
G61.81 Chronic inflammatory demyelinating polyneuritis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 0.5/100,000 children; 1 to 2/100,000 adults
PREDOMINANT SEX AND AGE: Slightly higher in males
RISK FACTORS: It is associated with certain systemic medical conditions (see under "Differential Diagnosis"), but the association is unclear.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symmetric weakness in both proximal and distal muscles that peaks after at least 8 wk; onset may appear acute in a minority of patients, and the disease course may be either relapsing or progressive.
- Impaired sensation with distal paresthesias, poor balance, and/or impaired proprioception.
- Reduced or absent deep tendon reflexes.
- Facial, oropharyngeal, and ocular involvement in a small minority of patients.
- Autonomic dysfunction occurs very infrequently compared with Guillain-Barré syndrome.

ETIOLOGY

Immune-mediated disorder emerging from interplay of both cell-mediated and humoral immune responses directed against incompletely characterized peripheral nerve antigens. May also be associated with antecedent illness, although no infectious etiologies have been consistently linked with disease occurrence.

DIAGNOSIS

There is no universal consensus regarding diagnostic criteria for CIDP. The three most widely used criteria are the American Academy of Neurology (AAN), Saperstein, and Inflammatory Neuropathy Cause and Treatment (INCAT) criteria. See Table E1 for a complete review of differences. Of note are the following:

- The AAN and INCAT criteria have the least stringent clinical criteria and require electrodiagnostic assessment of motor and sensory function in only one limb. The Saperstein criteria are more stringent, requiring both symmetrical proximal and distal weakness. Therefore, a patient with distal acquired demyelinating symmetric neuropathy (DADS) could fulfill AAN and INCAT criteria for CIDP.
- All require cerebrospinal fluid analysis to assess for albuminocytologic dissociation.
- All require some features of demyelination evident on nerve conduction studies, including prolonged distal latencies and F-waves, slowed conduction velocities, and at least one nerve demonstrating partial conduction block, a feature of acquired demyelination.
- INCAT criteria do not require a nerve biopsy.

DIFFERENTIAL DIAGNOSIS

- Other demyelinating neuropathies such as the following:
  1. Distal acquired demyelinating symmetric neuropathy (DADS)
  2. Multifocal motor neuropathy (MMN)
  3. Multifocal acquired demyelinating sensory and motor neuropathy (MADSAM; Lewis-Sumner syndrome)
- Inherited neuropathies: Charcot-Marie-Tooth subtypes
- Metabolic neuropathies due to diabetes, uremia
- Paraneoplastic and neoplastic neuropathies: Lymphoma and carcinoma
- Neuropathy associated with monoclonal gammopathy:
  1. Polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes (POEMS) syndrome
  2. Multiple myeloma
  3. Monoclonal gammopathy of undetermined significance (MGUS)
  4. Waldenström macroglobulinemia
- Neuropathy associated with infectious diseases: HIV and leprosy
- Neuropathy associated with systemic inflammatory or immune-mediated diseases:
  1. Sarcoidosis
  2. Amyloidosis
  3. Vasculitis: PAN, Behçet, Sjögren, cryoglobulinemia, lupus, Castleman disease, granulomatosis with polyangiitis (formerly Wegener granulomatosis), and eosinophilic granulomatosis with polyangiitis (formerly Churg-Strauss)
- Toxic neuropathies: ETOH, acrylamide, drugs (platinum-based agents, amiodarone, tacrolimus, perhexiline)

TABLE E1 Diagnostic Criteria

Feature	American Academy of Neurology (AAN) Criteria	Saperstein Criteria	Inflammatory Neuropathy Cause and Treatment Criteria
Clinical involvement	Motor dysfunction, sensory dysfunction of >1 limb or both	Major: Symmetric proximal and distal weakness; minor: exclusively symmetrical distal weakness or sensory loss	Progressive or relapsing motor and sensory dysfunction of >1 limb
Time course	≥2 mo	≥2 mo	≥2 mo
Reflexes	Reduced or absent	Reduced or absent	Reduced or absent
Electrodiagnostics	Any 3 of the following 4 criteria: Partial conduction block of ≥1 motor nerve, reduced velocity of ≥2 motor nerves, prolonged distal latency of ≥2 motor nerves, or prolonged F-waves of ≥2 motor nerves	2 of the 4 AAN electrodiagnostic criteria	Partial conduction block of ≥2 motor nerves and abnormal conduction velocity or distal latency or F-wave latency in 1 other nerve; or, in the absence of partial conduction block, abnormal conduction velocity, distal latency, or F-wave latency in 3 motor nerves; or electrodiagnostic abnormalities indicating demyelination in 2 nerves and histologic evidence of demyelination
CSF analysis	WBC count <10, negative CSF VDRL, and elevated protein (supportive)	Protein >45, WBC <10 (supportive)	CSF recommended but not mandatory
Biopsy findings	Evidence of demyelination and remyelination	Predominant features of demyelination; inflammation (not required)	Not mandatory (except in cases with electrodiagnostic abnormalities in only 2 motor nerves)

AAN, American Academy of Nursing; *CSF,* cerebrospinal fluid; *CSF VDRL,* neurosyphilis test; *WBC,* white blood cell.

WORKUP

Nerve conduction studies and EMG to assess for demyelinating polyneuropathy with features of acquired demyelination (temporal dispersion) and conduction block (Fig. E1)

LABORATORY TESTS

- CSF analysis to assess for albuminocytologic dissociation (i.e., elevated protein with normal cell count), along with appropriate laboratory studies to exclude associated conditions.
- Nerve biopsy specimens (rarely done now) also reveal signs of demyelination with variable degrees of inflammation and secondary axonal loss.

IMAGING STUDIES

MRI with/without gadolinium of the lumbar spine may show enlargement and enhancement of the proximal nerve root segments (Figs. E2 and E3).

Rx TREATMENT

Therapies are directed at blocking the underlying immune processes to arrest demyelination and inflammation and to prevent secondary axonal degeneration. The first-line agents for immunomodulatory therapy are intravenous immunoglobulin (IVIg), plasmapheresis, and corticosteroids. There is no difference in efficacy among these three treatment modalities. Azathioprine, mycophenolate mofetil, cyclophosphamide, rituximab, and cyclosporine may be used second-line.

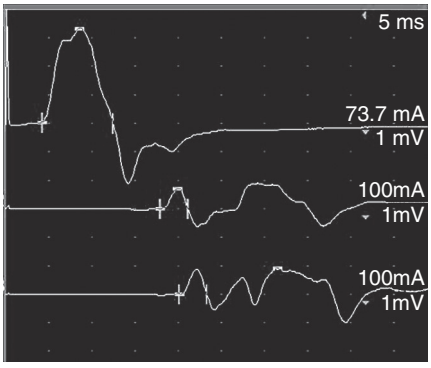

FIG. E1 Conduction block.

NONPHARMACOLOGIC THERAPY

Orthotics or braces may be useful for significant distal weakness.

ACUTE GENERAL Rx

- Prednisone 60 mg per day or 100 mg every other day
- IVIg 2 g/kg divided over 2 to 5 days
- Plasmapheresis (5 to 6 exchanges)

CHRONIC Rx

- Oral prednisone: 1 mg/kg daily starting dose, typically changed to every other day after 1 mo or when strength plateaus. Reduce by 10 mg per mo until dose reaches 20 mg every other day; then reduce by 5 mg per mo. Supplement calcium and vitamin D. Patients should receive a tuberculin skin test prior to administration as well as surveillance exams for cataracts, glaucoma, diabetes, and gastroesophageal reflux.
- Dexamethasone: PREDICT study compared dexamethasone 40 mg daily for 4 days per mo with prednisone 60 mg daily for 2 mo and then tapered over 27 wk. No difference in efficacy was found between the two groups. However, pulse steroids were associated with less weight gain, fewer cushingoid features, but more sleep and psychological disturbances.
- Pulse methylprednisolone: No standard regimen. However, 1000 mg for 3 days can be used, followed by 1000 mg per wk with the goal of reduced frequency to every 2 to 12 wk.
- IVIg: 0.4 to 1 g/kg administered every 2 to 3 wk, with adjustment based on therapeutic response. Baseline IgA level, renal function, and coagulation studies should be assessed.
- Mycophenolate mofetil: Initial dose of 500 mg every other day; increase to 2 g orally divided twice daily in 2 to 4 wk. Complete blood counts and liver panel should be assessed monthly for the first 3 mo, then every 3 mo thereafter. May cause GI upset.
- Azathioprine: Initial dose of 25 to 50 mg every other day; increase to 100 mg twice daily in 4 wk. Complete blood counts and liver panel should be assessed for first 3 mo, then every 3 mo thereafter. Idiosyncratic reaction of fever and GI upset may occur.
- Cyclophosphamide: Used for severe cases. 1000 mg/m^2 monthly for 6 mo (moderate dose) or 50 mg/kg daily for 4 days (high dose).
- Other treatments used (case reports/anecdotal evidence): Etanercept, rituximab, tacrolimus, interferon beta-1a.

FIG. E2 Contrast-enhanced magnetic resonance image shows enhancement of nerve roots.

FIG. E3 T2-weighted axial magnetic resonance image shows enlarged nerve roots.

PROGNOSIS

- Although available data on the long-term prognosis of patients are limited, most patients improve and reach stability. Relapses may occur in 50% of patients. A small minority of patients remain severely disabled, and up to 11% die from the disease.
- Patients with CIDP associated with IgM monoclonal gammopathy often respond poorly to treatment.
- Younger age, female gender, and relapsing-remitting course may portend a more favorable prognosis. Four-limb weakness at onset and prominent axonal loss on EMG may signify poor prognosis.

REFERRAL

- Neurologist, physical therapy/occupational therapy, orthotics

PEARLS & CONSIDERATIONS

- Patients are compliant with azathioprine treatment if MCV >100.
- Always place PPD prior to initiation of steroid treatment.
- Consider trimethoprim-sulfamethoxazole 3 times weekly in patients taking steroids and other immunosuppressant agents for *Pneumocystis* pneumonia prophylaxis (especially in patients with coexisting lung disease).
- Look for acquired features of demyelination on nerve conduction studies (conduction block and temporal dispersion).
- Examine CSF for albuminocytologic dissociation (high CSF protein with normal cell count).
- CIDP can present like Guillain-Barré syndrome. Sensory symptoms and proximal weakness are more common in CIDP, and symptoms continue to evolve over more than 8 wk.

PATIENT & FAMILY EDUCATION

CIDP is a chronic illness usually characterized by a relapsing-remitting course that typically responds well to treatment. Early referral to a neurologist is important, and education on steroid side effects and mitigating factors is paramount.

AUTHORS: **Chloe Mander Nunneley, MD, Joseph S. Kass, MD, JD, FAAN,** and **John Sladky, MD**

BASIC INFORMATION

DEFINITION

Chronic kidney disease (CKD) is diagnosed when there is evidence for more than 3 mo of **kidney damage** (urine albumin >30 mg/g creatinine, hematuria, or parenchymal abnormalities) and/or **decreased kidney function** (glomerular filtration rate, GFR <60 ml/min per 1.73 m^2). CKD is characterized by accumulation of metabolic waste products in blood, electrolyte abnormalities, mineral and bone disorders, and anemia. The pathophysiology of CKD and its manifestations are summarized in Table 1.

SYNONYMS

CKD
Chronic renal failure
CRF
Chronic renal insufficiency
CRI

ICD-10CM CODES

N18.1	Chronic kidney disease, stage 1
N18.2	Chronic kidney disease, stage 2
N18.3	Chronic kidney disease, stage 3
N18.4	Chronic kidney disease, stage 4
N18.5	Chronic kidney disease, stage 5
N18.6	End-stage renal disease
N18.9	Chronic kidney disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Overall prevalence of CKD (Stages 1 to 5) in the U.S. adult population is about 15% based on the 2018 United States Renal Data System. The incidence of end-stage renal disease (ESRD) is 7% to 9% per yr in the U.S., primarily due to diabetes mellitus and hypertension, the leading risk factors for CKD. Annually, 3 in 10,000 persons develop ESRD, and more than 100,000 patients begin dialysis each yr.
- Total Medicare spending on CKD and ESRD patients exceeds $114 billion USD. Accompanying chronic diseases such as diabetes and heart failure compound the cost of caring for these individuals, and kidney disease has been deemed a "cost multiplier" for this reason.
- Kidney transplantation is the best option for kidney replacement therapy, but many patients are not eligible for transplantation.

TABLE 1 Pathophysiology of Chronic Kidney Disease

Manifestation	Mechanisms
Accumulation of nitrogenous waste products	Decrease in glomerular filtration rate
Acidosis	Decreased ammonia synthesis Impaired bicarbonate reabsorption Decreased net acid excretion
Sodium retention	Excessive renin production Oliguria
Sodium wasting	Solute diuresis Tubular damage
Urinary concentrating defect	Solute diuresis Tubular damage
Hyperkalemia	Decrease in glomerular filtration rate Metabolic acidosis Excessive potassium intake Hyporeninemic hypoaldosteronism
Renal osteodystrophy	Impaired renal production of 1,25-dihydroxycholecalciferol Hyperphosphatemia Hypocalcemia Secondary hyperparathyroidism
Growth retardation	Inadequate caloric intake Renal osteodystrophy Metabolic acidosis Anemia Growth hormone resistance
Anemia	Decreased erythropoietin production Iron deficiency Folate deficiency Vitamin B_{12} deficiency Decreased erythrocyte survival
Bleeding tendency	Defective platelet function
Infection	Defective granulocyte function Impaired cellular immune functions Indwelling dialysis catheters
Neurologic symptoms (fatigue, poor concentration, headache, drowsiness, memory loss, seizures, peripheral neuropathy)	Uremic factor(s) Aluminum toxicity Hypertension
Gastrointestinal symptoms (feeding intolerance, abdominal pain)	Gastroesophageal reflux Decreased gastrointestinal motility
Hypertension	Volume overload Excessive renin production
Hyperlipidemia	Decreased plasma lipoprotein lipase activity
Pericarditis, cardiomyopathy	Uremic factor(s) Hypertension Fluid overload
Glucose intolerance	Tissue insulin resistance

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Skin pallor, ecchymosis
- Sleep disorder
- Hypertension
- Edema, leg cramps, restless legs, peripheral neuropathy
- Emotional lability, depression, decreased cognitive function
- Clinical presentation varies with the degree of kidney disease and its underlying etiology. Common symptoms are generalized fatigue, nausea, anorexia, pruritus, sleep disturbances, smell and taste disturbances, hiccoughs, and seizures

ETIOLOGY

- Diabetes (43.2%), hypertension (23%), chronic glomerulonephritis (12.3%)
- Failed kidney transplant
- Polycystic kidney disease (2.9%)
- Interstitial nephritis (e.g., drug hypersensitivity, analgesic nephropathy)
- Obstructive nephropathies (e.g., nephrolithiasis, prostatic disease)
- Vascular diseases (renal artery stenosis, hypertensive nephrosclerosis)
- Autoimmune diseases

DIAGNOSIS

GFR is considered the best overall index of kidney function but is not the only measure of kidney health that should be considered. Although quantification of albuminuria has been less widely adopted in clinical practice than assessment of estimated GFR (eGFR), the evaluation of albuminuria is crucial to determining prognosis. When applying eGFR equations, one must appreciate that CKD is defined over a 3-mo interval with implications for health. (Table 2)

Therefore the serum creatinine must be repeated and trended to establish a diagnosis of CKD in individuals who also must be in a steady state of creatinine generation or production. The albuminuria is complementary to low eGFR because both independently influence prognosis.

WORKUP

- Laboratory evaluation and imaging studies can identify reversible causes of acute GFR decline (e.g., volume depletion, urinary tract obstruction, heart failure).

- Ultrasound evaluation of the kidneys often reveals small kidneys (<9 cm sagittal length) with increased echogenicity.
- Kidney biopsy is generally not considered when kidneys are small or CKD is advanced.
- Table 3 provides a summary of a practical approach to the detection and management of CKD.

LABORATORY TESTS

- Elevated blood urea nitrogen (BUN), creatinine, and low GFR are the best overall indicators of kidney function. GFR is estimated by multivariable (creatinine, age, sex, and race) prediction equations normalized to body surface area. GFR calculators are available online (www.kidney.org/kls/professionals/gfr_calculator.cfm). The Modification of Diet in Renal Disease (MDRD) equation has been in common use in clinical laboratories until recently, but has been replaced by the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation that more accurately categorizes the risk of mortality and progression to ESRD.
- Urinalysis may reveal proteinuria, hematuria, or formed elements such as casts.
- Serum chemistries: Elevated BUN and creatinine, hyperkalemia, hyperuricemia, hypocalcemia, hyperphosphatemia, hyperglycemia, and decreased serum bicarbonate concentration.
- Urinary protein excretion. A urine total protein-to-creatinine ratio >1000 mg/g or albumin-to-creatinine ratio of >500 mg/g creatinine generally indicates glomerular disease.
- Special studies: Serum and urine immunoelectrophoresis (multiple myeloma), antinuclear antibody (i.e., systemic lupus erythematosus).
- Cystatin C measurement or direct glomerular filtration clearance methods may confirm CKD in situations when serum creatinine-based GFR equations are less accurate (e.g., HIV, malnutrition) or more precise measurement is desired (e.g., kidney transplant organ donation).

IMAGING STUDIES

- Ultrasound of kidneys for size measurements and to rule out cause of obstructive uropathy
- Plain radiographs of the aorta and extremities ordered for other reasons may reveal vascular and extraskeletal calcification

TABLE 2 Criteria for Definition of Chronic Kidney Disease

KD is defined as abnormalities of kidney structure or function, present for more than 3 mo, with implications for health. These may include the following:

Markers of kidney damage	Albuminuria (AER ≥30 mg/24 h; uACR ≥30 mg/g [≥3 mg/mmol]) Urine sediment abnormalities Electrolyte and other abnormalities caused by tubular disorders Abnormalities detected through histology Structural abnormalities detected through imaging History of kidney transplantation
Decreased GFR	GFR <60 ml/min/1.73 m^2

AER, Albumin excretion rate; *GFR,* glomerular filtration rate; *uACR,* urine albumin-to-creatinine ratio.
From KDIGO 2012 Clinical practice guideline for the evaluation and management of chronic kidney disease. *Kidney Int Suppl* 2013;3:1-150. In Floege J et al: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Elsevier. Table 80.1

TABLE 3 Management Plan for Patients with Chronic Kidney Disease, According to Stage

Stage & GFR	Action	Clinical Testing	Treatment Considerations
1 **>90 ml/min per 1.73 m^2**	**Establish** risk or etiology of CKD **Diagnose** and treat CVD risk factors and comorbid conditions	***eGFR*:** *Every* 12 mo **UA** with microscopic evaluation **UPC** if nondiabetic**:** *Every* 12 mo **UACR** if diabetic**:** *Every* 12 mo	**Consult** nephrology if ***eGFR*** declines by ≥4 ml/min per yr **BP:** <130/80 mm Hg **Proteinuria:** UPC <0.2**;** UACR <30 mg/g with ACEI or ARB
2 **60-89 ml/min per 1.73 m^2**	**Estimate** CKD progression rate **Diagnose** and treat CVD risk factors and comorbid conditions	***eGFR*:** *Every* 6-12 mo **CBC**, reticulocyte ct, TSAT, ferritin if Hb 10-12 g/dl**:** every 12 mo **Annual** Ca/P/PTH/25(OH)D evaluations **UACR** or UPC**:** *Every* 6-12 mo	**Avoid** nephrotoxins **Treat** Hypertension **Hb:** 10-12 g/dl, TSAT >20%, and ferritin >100 ng/ml **UACR:** <30 mg/g or UPC <0.2 with ACEI or ARB
3A **45-59 ml/min per 1.73 m^2** **3B** **30-44 ml/min per 1.73 m^2**	**Estimate** CKD progression rate **Diagnose** and treat CVD risk factors and comorbid conditions **Kidney** imaging study (e.g., US or CT) **Consider** nephrology **Consultation**	**BP** monitoring**:** *Every* 3-6 mo ***eGFR*:** *Every* 6 mo, if stable every 12 mo **CBC:** Hb <10 g/dl *every* 1-3 mo until Hb 9-12 g/dl**;** then *every* 3-6 mo **TSAT** and ferritin if Hb <13 g/dl (males) or 12 g/dl (females) and after therapy **Baseline** Ca/P/PTH/Alk Phos/25(OH)D Ca/P/PTH/Alk Phos, depending on baseline and CKD progression **25(OH)D**, depending on baseline and response to treatment **UPC or UACR:** *Every* 6-12 mo	**Avoid** nephrotoxins **Treat** Hypertension **Hb:** 9-12 g/dl, TSAT >20%, ferritin >100 ng/ml with p.o. and/or *iv* iron and/or erythropoiesis stimulating agent **Ca & P:** To normal range with P-binders **25(OH)D:** ≥30 ng/ml with vitamin D2/D3 **iPTH:** 130-600 pg/ml with calcitriol or vitamin D analogs if iPTH progressively increases **NaHCO3:** 22-26 mmol/L and titrate $NaHCO_3$ therapy **UPC:** <0.2 or UACR <30 mg/g with ACEI or ARB
4 **15-29 ml/min per 1.73 m^2**	Transition of management and care to Nephrology **Initiate** decisions regarding kidney replacement therapy, vascular access, and kidney transplant **Diagnose** and treat CVD risk factors and comorbid conditions **Adjust** drug dosing for CKD stage	**BP** monitoring**:** *Every* 3 mo ***eGFR*:** *Every* 3 mo **CBC**, TSAT, ferritin**:** *Every* 3-6 mo **Baseline** Ca/P/PTH/Alk Phos/25(OH)D**;** then repeat levels *every* 6-12 mo **UPC or UACR:** *Every* 3-6 mo	**All of the above plus CKD**-specific education**:** Kidney replacement therapy modality **Immunizations:** TIV, PPV-23, and HBV **Reinforce** dietary prescription **Protect** dominant (handwriting) arm **Vascular** access surgery evaluation

ACEI, Angiotensin-converting enzyme inhibitors; *ARB*, angiotensin-receptor blockers; *BP*, blood pressure; *CKD*, chronic kidney disease; *CT*, computed tomography; *ct*, count; *CVD*, cardiovascular disease; *eGFR*, estimated glomerular filtration rate; *HBV*, hepatitis B virus; *TSAT*, transferrin saturation; *UA*, urine analysis; *UACR*, urine albumin to creatinine ratio; *UPC*, urine protein test; *US*, ultrasonography.
CKD Stage 5 (GFR <15 ml/min/1.73 m^2) patients require management by a nephrologist.
From Inker LA, Astor BC, Fox CH, et al.: *Am J Kidney Dis* 63(5);713–735, 2014.4

CLASSIFICATION

The 2012 Kidney Disease: International Global Outcomes classifies CKD with a CGA format: Cause (etiology), GFR (G1 to G5), and Albuminuria (A1 to A3) by urine albumin-to-creatinine ratio. This format now is recommended when documenting and discussing CKD. Fig. 1 depicts how CKD prognosis worsens with either increasing levels of albuminuria or declining GFR.

Rx TREATMENT

CKD usually progresses slowly. Therefore even relatively small reductions in GFR loss can delay the onset of ESRD by years. For this reason, an aggressive, multiple–risk factor intervention to slow GFR decline is warranted, except in patients with low ESRD risk. The goals of progression therapy are to reduce proteinuria as much as possible, ideally to less than 500 mg/day, which is a safe level of proteinuria for most forms of CKD, and to slow GFR decline as much as possible, ideally to about 1 ml/min/yr, which is the rate of GFR decline attributable to the nephropathy of aging. Table 4 summarizes recommended kidney protective therapies according to level of recommendation.

NONPHARMACOLOGIC THERAPY

KDIGO has recommended that protein intake should be lowered to 0.8 g/kg/day in adults with CKD and GFR below 30 ml/min/1.73 m^2, whereas high protein intake (>1.3 g/kg/day) should be avoided in adults with CKD at risk of progression. Table 5 describes nutritional recommendations in CKD.

- Referral to a dietitian for nutritional therapy for patients with GFR <50 ml/min/1.73 m^2 is recommended and is a Medicare-covered service.
- Dietary restriction of sodium (~100 mmol/day), potassium (≤60 mmol/day), and phosphorus (<800 mg/day).
- Blood pressure: Target blood pressure of ≤140/90 mm Hg if CKD (diabetic and nondiabetic) and urine albumin excretion ≤30 mg/24 hr. If CKD (diabetic and nondiabetic) and albumin excretion >30 mg/24 hr are present, consider a target blood pressure ≤130/80 mm Hg.
- Adjust medication doses for reduced GFR.
- Restrict fluid intake if significant edema or hyponatremia (serum Na <130 mmol/L) is present.
- Resistance exercise training can preserve lean body mass and improve nutritional status and muscle function in patients with moderate CKD.
- Avoid radiocontrast agents. Prophylactic volume expansion with sodium chloride or sodium bicarbonate before dye exposure is equally effective.
- Smoking cessation.
- Prompt referral to a nephrologist is helpful. Late evaluation of patients with CKD is associated with greater burden and severity of comorbid disease and complications and lesser survival. Suggested criteria for nephrology referral are described in Table 6.
- Referral for kidney transplantation in selected patients.

ACUTE GENERAL Rx

- Angiotensin–converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) reduce proteinuria and slow progression of CKD, especially in hypertensive diabetic

CKD is classified based on: • Cause (C) • GFR (G) • Albuminuria (A)				Albuminuria categories Description and range		
				A1	A2	A3
				Normal to mildly increased	Moderately increased	Severely increased
				<30 mg/g < mg/mmol	30-299 mg/g 3-29 mg/mmol	≥300 mg/g ≥30 mg/mmol
GFR categories (ml/min/1.73m^2) Description and range	G1	Normal or high	≥90	1 if CKD	Treat 1	Refer* 2
	G2	Mildly decreased	60-89	1 if CKD	Treat 1	Refer* 2
	G3a	Mildly to moderately decreased	45-59	Treat 1	Treat 2	Refer 3
	G3b	Moderately severely decreased	30-44	Treat 2	Treat 3	Refer 3
	G4	Severely decreased	15-29	Refer* 3	Refer* 3	Refer 4+
	G5	Kidney failure	<15	Refer 4+	Refer 4+	Refer 4+

FIG. 1 Risk of chronic kidney disease progression, frequency of visits, and referral to nephrology according to estimated glomerular filtration rate (eGFR) and albuminuria. The GFR and albuminuria grid depict the risk of progression, morbidity, and mortality by color, from best to worst (green, yellow, orange, red, deep red). The numbers in the boxes are a guide to the frequency of visits (number of times per yr). Green can reflect CKD with normal eGFR and albumin-to-creatinine ratio (ACR) only in the presence of other markers of kidney damage, such as imaging showing polycystic kidney disease or kidney biopsy abnormalities, with follow-up measurements annually; yellow requires caution and measurements at least once per yr; orange requires measurements twice per yr; red requires measurements 3 times per yr; and deep red 4 times per yr. These are general parameters only, based on expert opinion, and must take into account underlying comorbid conditions and disease state as well as the likelihood of impacting a change in management for any individual patient. "Refer" indicates nephrology services are recommended. *Referring clinicians may wish to discuss with their nephrology service, depending on local arrangements regarding treating or referring. *CKD,* Chronic kidney disease; *GFR,* glomerular filtration rate. (From Vassalotti JA et al: Practical approach to detection and management of chronic kidney disease for the primary care clinician. *Am J Med* 2016 Feb, Elsevier.)

patients. The combination of ACEI and ARB is not recommended due to increased risks of hyperkalemia, hypotension, and acute kidney injury. Increases of serum creatinine of up to 30% greater than baseline within 3 mo of initiating ACEI or ARB therapy may be acceptable.
- Addition of chlorthalidone to CKD patients with difficult-to-treat hypertension may reduce blood pressure and proteinuria. Successful blood pressure lowering is associated with weight loss. Loop diuretic therapy may be associated with complications of hypokalemia.
- Erythropoiesis-stimulating agents (ESAs), e.g., epoetins alfa and beta and darbepoetin alfa, are administered to reduce need for transfusions in anemic CKD patients. A target hemoglobin of 9 to 11 g/dl is reasonable to avoid premature and excessive ESA use. Higher hemoglobin values have been associated with adverse cardiovascular events. Iron sufficiency should be present, defined as transferrin saturation >20% and ferritin >100 ng/ml, before ESA therapy is initiated.
- Optimal diuretic therapy should be prescribed for edema or cardiopulmonary congestion.
- ACEIs and ARBs retard progression of CKD and lower blood pressure but may reduce GFR and renal potassium excretion.
- Treat metabolic acidosis with oral sodium bicarbonate to attain a goal serum HCO_3 level of 22 to 26 mmol/L.

TABLE 4 Recommended Kidney Protective Therapies According to Level of Recommendation

Level 1 Recommendations
- Control blood pressure (BP).
- Administer angiotensin-converting enzyme inhibitor, angiotensin receptor blocker, or renin inhibitor.
- Avoid dihydropyridine calcium channel blockers (DH-CCBs) unless needed for BP control.
- Control protein intake.

Level 2 Recommendations
- Restrict NaCl intake/diuretic therapy.
- Administer nondihydropyridine calcium channel blockers (NDH-CCB) therapy.
- Control each component of the metabolic syndrome.
- Administer aldosterone antagonist therapy.
- Administer β-blocker therapy.
- Control serum phosphorus.
- Instigate smoking cessation.
- Control hyperuricemia.
- Administer alkali therapy.
- Avoid anticoagulant-related nephropathy.
- Monitor serum creatinine in patients receiving proton pump inhibitors.
- Correct vitamin D deficiency.
- Avoid/minimize nonsteroidal antiinflammatory drug use.
- The goal for the chronic kidney disease (CKD) patient is to implement all level 1 recommendations and as many level 2 recommendations as is feasible.

From Floege J et al: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Elsevier. Box 79.3.

- Statin or a combination of statin and ezetimibe is recommended in adults aged ≥50 yr with eGFRs <60 ml/min/1.73 m^2. Lipid management focuses on absolute risk for coronary events, and there are no target cholesterol levels.
- Therapy of mineral and bone disease in CKD is geared toward normalizing serum phosphorus concentration. Calcitriol and vitamin D analogs should be reserved for patients with CKD stages 4-5 and severe and progressive hyperparathyroidism.
- Dietary phosphate restriction is recommended for nearly all CKD patients. For additional management of hyperphosphatemia, phosphorus binders are recommended. Calcium-based phosphate binders, although inexpensive, should be restricted if total serum calcium is >10.2 mg/dl. Sevelamer carbonate and lanthanum carbonate are effective as phosphate binders but more expensive. Two iron-based phosphate-binding agents, sucroferric oxyhydroxide and ferric citrate, recently have been approved by the FDA.
- Uremic pruitus: Difelikefalin, a selective agonist of kappa opioid receptors has shown a significant reduction in itch intensity in Phase 3 tumors in hemodialysis patients with pruritus.
- Recommendations of the current CDC advisory committee on immunization practices call for pneumococcal vaccination of individuals >19 yr at the time of CKD diagnosis. In addition routine annual influenza vaccination for all persons aged ≥6 mo who do not have contraindications has been recommended. Those at high risk of progression of CKD with eGFR below 30 ml/min/1.73 m^2 should be immunized against hepatitis B to ensure seroconversion.
- Initiation of dialysis: Early initiation of dialysis when the GFR is 10 to 15 ml/min/1.73 m^2 does not enhance survival compared with

TABLE 5 Nutritional Recommendations in Chronic Kidney Disease.

Recommendations are for typical patients but always should be individualized on the basis of clinical, biochemical, and anthropometric indices.

Daily Intake	Predialysis CKD	Hemodialysis	Peritoneal Dialysis
Protein (g/kg ideal BW) (see KDOQI for estimation of adjusted edema-free BW)	0.6-1.0 Level depends on the view of the nephrologist. 1.0 for nephrotic syndrome.	min ≥1.1 Recommendations are in conjunction with an adequate energy intake. Requirements may be higher during illness because of multiple comorbidities or during acute periods of infection, including peritonitis.	min 1.0-1.2
Energy (kcal/kg BW)	35 (younger than 60 yr) 30-35 (older than 60 yr)	35 (younger than 60 yr) 30-35 (older than 60 yr) 30-40 kcal/kg ideal BW	35 including dialysate calories (younger than 60 yr) 30-35 including dialysate calories (older than 60 yr)
Sodium (mmol)	<100 (more if salt wasting)	<100	<100
Potassium	Reduce if hyperkalemic	Reduce if hyperkalemic	Reduce if hyperkalemic; potassium restriction is generally not required. May need to increase potassium intake if hypokalemic.
	If hyperkalemic, advice will take the form of decreasing certain foods (e.g., some fruits and vegetables) and giving information about cooking methods.		
Phosphorus	Reduce because of phosphate retention. Monitor levels. Advice will take the form of reducing certain foods (e.g., dairy, offal, some shellfish) and processed foods with high content of added phosphates, and giving information about the timing of binders with high-phosphorus meals and snacks.		

Recommendations are for typical patients but always should be individualized based on clinical, biochemical, and anthropometric indices. *BW,* Body weight; *CKD,* chronic kidney disease; *KDOQI,* Kidney Disease Outcomes Quality Initiative.

From Floege J et al: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Elsevier. Table 86.6.

TABLE 6 Suggested Criteria for Referral of Patients with Chronic Kidney Disease to a Nephrologist

	NICE 2008	KDIGO 2012
Advanced CKD	Stage 4 and 5 CKD	Category G4 and G5 CKD
Proteinuria	High proteinuria: ACR ≥70 mg/mmol unless known to be caused by diabetes and appropriately treated	Consistent proteinuria: ACR ≥ 300 mg/g (≥30 mg/mmol)
Hematuria	Proteinuria (ACR ≥30 mg/mmol) together with hematuria	Urinary red cell casts, RBCs >20 per high-power field sustained; not readily explained
Progression of CKD	Rapidly declining eGFR: >5 ml/min per 1.73 m^2 in 1 yr >10 ml/min per 1.73 m^2 in 5 yr	Progression of CKD: Sustained decline in eGFR >5 ml/min per 1.73 m^2 in 1 yr Drop in GFR category with a ≥25% drop in eGFR from baseline
Uncontrolled hypertension	Hypertension that remains poorly controlled despite the use of at least four antihypertensive drugs at therapeutic doses	CKD and hypertension refractory to treatment with four or more antihypertensive agents
Hereditary kidney disease	Known or suspected rare or genetic causes of CKD	Hereditary kidney disease
Other conditions	Suspected renal artery stenosis	Recurrent or extensive nephrolithiasis Persistent abnormalities of serum potassium

ACR, Albumin-creatinine ratio; *CKD,* chronic kidney disease; *eGFR,* estimated glomerular filtration rate; *KDIGO,* Kidney Disease: Improving Global Outcomes; *NICE,* National Institute for Health and Care Excellence; *PTH,* parathyroid hormone; *RBC,* red blood cell.

From Floege J et al: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Elsevier. Table 80.3) (Data from KDIGO 2012 Clinical Practice Guideline for the Evaluation and Management of Chronic Kidney Disease. *Kidney Int Suppl* 2013; 3: pp. 1-150; and National Institute for Health and Care Excellence: *chronic kidney disease in adults: assessment and management*.

a symptom-driven strategy for initiation of dialysis at eGFR <8 to 10 ml/min/1.73 m^2.

1. Urgent indications: Uremic pericarditis, neuropathy, neuromuscular abnormalities, CHF, hyperkalemia, seizures.
2. Other indications: GFR 10 to 15 ml/min with progressive anorexia, weight loss, disordered sleep, pruritus, uncontrolled fluid gain with hypertension, and signs of heart failure.

DISPOSITION

- Prognosis is influenced by CKD stage and burden of comorbid illness. Late referral, meaning nonreferral within 6 to 12 mo before a diagnosis of ESRD is established, of patients to a nephrologist is associated with greater morbidity and mortality. Despite recommendations for early referral, nearly two thirds of CKD patients are referred late.
- *Choosing Wisely* is an initiative of the ABIM Foundation that aims to promote conversations between clinicians and patients by helping patients choose care that is supported by evidence and avoids wasteful or unnecessary medical tests, treatments, and procedures.
- Genetic susceptibility for CKD is prominent in African Americans. High-risk alleles of apolipoprotein L1 predict more rapid CKD progression independent of diabetes, race, and lipid and nonlipid factors.
- Kidney transplantation in selected patients improves survival. Whereas the 2-yr kidney graft survival rate for living related donor transplantations is >80%, the 2-yr graft survival rate for cadaveric donor transplantation is nearly 70%.

Chronic Lymphocytic Leukemia PTG ALG

BASIC INFORMATION

DEFINITION

Chronic lymphocytic leukemia (CLL) is a lymphoproliferative disorder characterized by proliferation and accumulation of mature-appearing neoplastic B cells.

SYNONYM

CLL

ICD-10CM CODES

C91.10	Chronic lymphocytic leukemia of B-cell type not having achieved remission
C91.11	Chronic lymphocytic leukemia of B-cell type in remission
C91.12	Chronic lymphocytic leukemia of B-cell type in relapse

EPIDEMIOLOGY & DEMOGRAPHICS

- Most frequent form of leukemia in Western countries (20,940 new cases and 4510 deaths annually in the U.S.). Incidence rate is 5 per 100,000 person-yr, increasing to 17 cases per 100,000 at age 65. It is more common in patients with a family history of CLL or other lymphoid malignancy
- Generally occurs in older patients: Median age at diagnosis in the U.S. is 70 yr
- Male/female ratio of 2:1
- CLL accounts for 1% of all cancers and 11% of all hematologic neoplasms
- May be preceded by monoclonal B-cell lymphocytosis—a premalignant, asymptomatic condition with less than 5000 /mm^3 CLL-like cells circulating in the blood

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- At presentation most patients are asymptomatic. Many cases are diagnosed on the basis of incidentally discovered lymphocytosis.
- Symptoms include fatigue, recurrent infections (pneumonia, herpes zoster), enlarging lymph nodes.
- B symptoms (fever, weight loss, and drenching night sweats) occur in 10% of patients at presentation.
- Small diffuse lymphadenopathy and splenomegaly are typical findings on clinical examination, but they are absent in a majority of patients at diagnosis.
- A minority of CLL patients (<10%) may develop autoimmune hemolytic anemia or immune thrombocytopenia at diagnosis or during the course of the disease.
- At a rate of 1% per yr, CLL may undergo a histologic transformation into an aggressive lymphoma (Richter transformation), characterized by a rapidly growing nodal mass, elevated LDH, and constitutional symptoms.

ETIOLOGY

Remains largely unknown. Accumulation of genetic defects causing resistance to apoptosis and chronic stimulation of the B-cell receptor by autoantigens or undefined microorganisms have been implicated.

DIAGNOSIS

- The diagnosis of CLL requires presence of >5000/mm^3 clonal B cells, for >3 mo, with a characteristic immunophenotype on flow cytometry, which is essential for diagnosis.
- CLL cells are typically positive for CD5, CD19, CD23 and weakly positive for CD20, while they are negative for CD10, Cyclin D1, and CD103. In some cases, molecular studies for CLL-specific chromosomal alterations (deletion of chromosome 13q, 11q, 17p or trisomy 12) may be helpful.
- Table 1 describes the evaluation of CLL patients at diagnosis.

DIFFERENTIAL DIAGNOSIS

- Few acute infections with lymphocytosis (mononucleosis, pertussis)
- Other lymphoproliferative disorders that involve blood (can be distinguished using flow cytometry): Follicular lymphoma, mantle cell lymphoma, splenic marginal zone lymphoma, prolymphocytic leukemia, adult T-cell lymphoma/leukemia, hairy cell leukemia (Table 2)
- Acute lymphocytic leukemia can be differentiated by presence of lymphoblasts rather than mature lymphocytes
- Persistent polyclonal B-cell lymphocytosis: A rare, benign condition affecting (predominantly female) middle-aged smokers
- Differences among monoclonal B-cell lymphocytosis (MBL), CLL, and small lymphocytic leukemia (SLL) are summarized in Table 3

LABORATORY TESTS

- Complete blood count demonstrates lymphocytosis with mature lymphocytes and characteristic "smudge cells" on the peripheral smear (Fig. E1); anemia and thrombocytopenia may be present in more advanced cases.
- Bone marrow examination is **not** indicated in most cases, except when differentiation between autoimmune cytopenias and marrow infiltration by CLL is difficult.
- Hypogammaglobulinemia and elevated lactate dehydrogenase may be present at the time of diagnosis.
- Cytogenetic evaluation (using fluorescent *in-situ* hybridization, FISH) is essential for prognostic assessment and optimal treatment selection.
- Other prognostic markers include: Mutational status of the immunoglobulin heavy chain variable region (*IGHV*, unmutated gene with >98% homology indicates poor prognosis), presence of CD38 or ZAP-70 (also associated with poor prognosis). Additional mutation analysis is gaining importance for identifying patients with worse prognosis (mutations in *TP53, NOTCH1, SF3B1,* and *BIRC3* genes).

TABLE 1 Evaluation of Chronic Lymphocytic Leukemia Patients at Diagnosis

History

- B symptom and fatigue assessment
- Infectious history assessment
- Occupational assessment for chemical exposure
- Familial history of CLL and lymphoproliferative disorders
- Preventive interventions for infections and secondary cancers

Physical Examination

Laboratory assessment

- CBC with differential
- Morphology assessment of lymphocytes
- Chemistry, LFT enzymes, LDH
- Flow cytometry assessment to confirm immunophenotype of CLL
- Serum immunoglobulins
- Serum β_2M levels
- Interphase cytogenetics for del(17p13.1), del(11q22.3), del(13q14), del(6q21), and trisomy 12
- IGHV mutational analysis
- Stimulated metaphase karyotype (if available)

Selected tests under certain circumstances

- DAT, haptoglobin, reticulocyte count if anemia present
- CT scan if unexplained abdominal pain or enlargement present
- PET scan or biopsy (or both) if large nodal mass present
- BM aspirate and biopsy if cytopenias present
- Familial counseling if first-degree relative with CLL

Teaching

IMAGING STUDIES

Imaging studies (CT or PET/CT scans) are not necessary for asymptomatic patients at diagnosis. They are obtained in case of clinical concerns for bulky internal adenopathy, Richter transformation, or prior to starting chemotherapy.

Rx TREATMENT

- At present, there is no standard curative therapy for CLL, so treatment is only instituted for progressive or symptomatic disease (Table 5) with a goal of symptom relief and prolongation of life.

TABLE 3 Characteristics of Monoclonal B-Cell Lymphocytosis (MBL), Chronic Lymphocytic Leukemia (CLL), and Small Lymphocytic Leukemia (SLL)

	MBL	CLL	SLL
Clonal B cells >5 × 10^9/L	No	Yes	No
Lymph nodes >1.5cm	No	Yes/No	Yes
Enlarged spleen or liver	No	Yes/No	Yes/No
Anemia	No	Yes/No	Yes/No
Thrombocytopenia	No	Yes/No	Yes/No
Bone marrow involvement ≥30%	Yes/No	Yes	No
Molecular prognostic factors predictive of outcome	No	Yes	Yes
Higher risk of infection	Yes	Yes	Yes
Higher risk of autoimmune problems	Yes	Yes	Yes

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

STAGING

Staging reflects the clinical burden of disease and aids assessment of prognosis and treatment decision making. The historical staging systems by Rai and Binet remain in clinical use. They use **only** physical examination and the CBC (i.e., no scans). The modified Rai system distinguishes three risk groups:

- Low risk (lymphocytosis alone, or Stage 0)
- Intermediate risk (presence of lymphadenopathy, hepatomegaly or splenomegaly, formerly Stage I/II)
- High risk (presence of anemia with hemoglobin <11 g/dl, or thrombocytopenia with platelet count <100,000/mm^3, formerly stage III/IV)

The Binet system divides CLL into three stages:

- Stage A: Involvement of <3 nodal areas (counting separately cervical, axillary, or inguinal lymph nodes, spleen, and liver)
- Stage B: Three or more areas involved
- Stage C: Presence of anemia (hemoglobin <10 g/dl) or thrombocytopenia (<100,000/mm^3), independent of the areas involved

Prognosis in CLL can be determined using the CLL-International Prognostic Index (CLL-IPI), which includes five factors: 17p/*TP53* status, *IGVH* mutational status, serum beta-2-microglobulin, Rai/Binet stage (0/A versus others), and age >65 yr. Overall 5-yr survival varies from 93% for the low-risk group to 23% for the very high-risk group (Table 4).

- "Watchful waiting" (i.e., observation without therapy) is the optimal strategy for all early-stage, asymptomatic patients outside of clinical trials because early chemotherapy provides no survival or quality-of-life benefit.
- Treatment with the Bruton tyrosine kinase (BTK) inhibitor ibrutinib or with immunochemotherapy is the standard of care for patients with symptoms related to disease, bulky adenopathy, rapidly increasing lymphocyte count, or progressive cytopenias (except for autoimmune cytopenias, which can be treated without chemotherapy).

ACUTE GENERAL Rx

- The initial chemotherapy is chosen depending on the patient's age, comorbidities, and CLL cytogenetics (Fig. 2).
- BTK inhibitor ibrutinib is the most effective first-line treatment strategy in every studied setting, demonstrating improved survival against aggressive immunochemotherapy in younger/fit patients, or against less intensive approaches in older patients. Its downsides include lack of complete remissions and need for long-term daily drug therapy. Combinations of ibrutinib with venetoclax for first-line therapy of CLL have shown impressive results in trials with almost all patients achieving a complete response without any added toxicity by combining the two drugs.[1]
- Ibrutinib is typically prescribed at the dose of 420 mg daily and is associated with diarrhea, increased risk of hypertension, atrial fibrillation (10%), and occasional bleeding (particularly with concurrent anticoagulants).
- Immunochemotherapy with fludarabine, cyclophosphamide, and rituximab (FCR) results in complete remission in 72% of patients, with about 30% remaining in remission after 12 yr of follow-up. It may be considered for fit patients younger than 65 yr with unmutated *IGVH*, but is associated with high rates of toxicity.
- Immunochemotherapy with bendamustine and rituximab or with chlorambucil and obinutuzumab is an option for older patients, and provides at least a partial remission for most patients, with median progression-free survival of about 2 to 4 yr.
- CLL with deletion 17p or *TP53* mutation does not respond well to standard immunochemotherapy, and BTK inhibitors are the standard approach.
- Recurrent CLL is often characterized by acquired deletion or mutation of the *TP53* gene and can also be treated with a variety of salvage regimens:
  1. Ibrutinib for patients who did not receive it as first line of treatment.
  2. Venetoclax, an oral BCL2 inhibitor, in combination with rituximab or alone; Venetoclax is characterized by a high response rate (79%) and risk of tumor lysis, requiring extremely careful dosing and monitoring in the first days of therapy.
  3. Idelalisib, an oral PI3K inhibitor.
  4. Anti-CD20 monoclonal antibodies: Ofatumumab, obinutuzumab, rituximab, alone or in combination with chemotherapy: Purine analogues (fludarabine, pentostatin), alkylating agents (bendamustine, cyclophosphamide, CHOP-like combinations).
  5. Alemtuzumab (anti-CD52 monoclonal antibody).
  6. High-dose methylprednisolone.
  7. Palliative radiation therapy to bulky lymph nodes or spleen.
- Allogeneic bone marrow transplantation is occasionally used for younger patients with recurrent, refractory, or ultra-high cytogenetic risk disease, but is associated with high rates of transplant-related mortality.

CHRONIC Rx

Treatment of systemic complications:

- Tumor lysis syndrome may occur during initial or subsequent chemotherapy but is extremely unlikely without chemotherapy in CLL, even with high lymphocyte counts.
- CLL patients are at increased risk of solid tumors and should adhere to age-appropriate screening modalities; skin cancers, including melanoma, are particularly common.
- Hypogammaglobulinemia is frequent in CLL and may cause recurrent infections, particularly pneumonias. Immunoglobulin supplementation (250 mg/kg IV every 4 wk) may prevent infections but has no effect on the course of CLL.

[1] Jain N et al: Ibrutinib and venetoclax for first-line treatment of CLL, *N Engl J Med* 380(22):2095-2103, 2019.

- Patients after chemoimmunotherapy are at risk for, and often ultimately succumb to, opportunistic infections. Herpes zoster and *Pneumocystis jiroveci* prophylaxis is used during and after some chemoimmunotherapy regimens.
- Novel targeted agents are associated with specific adverse effects during prolonged therapy. Ibrutinib may cause atrial fibrillation, chronic diarrhea, and hemorrhage and must be held before surgical procedures. Idelalisib may cause severe hepatitis and pneumonitis. Venetoclax may cause tumor lysis syndrome and neutropenia.
- Autoimmune hemolytic anemia, thrombocytopenia, and (rare) neutropenia may be treated with steroids, immunoglobulin, or immune suppression without cytotoxic chemotherapy.
- CLL is a contraindication to administration of live vaccines (varicella zoster, mumps/measles/rubella, yellow fever, intranasal influenza). Patients should adhere to the recommended schedule of immunization against *Pneumococcus* and influenza.

TABLE 4 Prognosis of Patients with CLL at the Time of Diagnosis, Stratified by the CLL-International Prognostic Index.

Number of High Risk Factors	Risk Group	Percent of Patients	Median Time to First Chemotherapy	Overall Survival at 5 yr
0-1	Low	38%	5-10 yr	93%
2-3	Intermediate	34%	4-5 yr	79%
4-6	High	23%	1-3 yr	63%
7-10	Very high	5%	<1 yr	23%

Risk factors include age >65 yr (1 point), stage Rai I-IV or Binet B-C (1 point), unmutated *IGVH* (2 points), beta-2-microglobulin >3.5 mg/L (2 points), or deletion 17p/*TP53* mutation (4 points). *CLL,* Chronic lymphocytic leukemia.

TABLE 5 Modified Indications for Treatment of Chronic Lymphocytic Leukemia

- Grade 2 or greater fatigue limiting life activities
- B symptoms persisting for ≥2 wk
- Lymph nodes >10 cm or progressively enlarging lymph nodes causing symptoms
- Spleen or liver with progressive enlargement or causing symptoms
- Anemia (hemoglobin <11 g/dl) referable to CLL
- Thrombocytopenia (platelets $<100 \times 10^{12}$/L) referable to CLL or ITP poorly responsive to traditional therapy
- Severe paraneoplastic (e.g., insect hypersensitivity, vasculitis, myositis) process related to CLL not responsive to traditional therapies

B symptoms, Fever, night sweats, weight loss; *CLL,* chronic lymphocytic leukemia; *ITP,* idiopathic thrombocytopenic purpura.
From Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.

DISPOSITION

Most patients die due to infectious complications of therapy for refractory disease after several lines of treatment. Histologic transformation to an aggressive lymphoma is also associated with high mortality. Palliative treatment should be offered to patients who are no longer benefiting from aggressive therapy to avoid pervasive and futile treatment with distressing complications.

BASIC INFORMATION

DEFINITION

Chronic myeloid leukemia (CML) is a malignant clonal stem disease characterized by the Philadelphia chromosome, an acquired cytogenetic abnormality arising out of the reciprocal translocation of long arms of the *ABL* and *BCR* genes on chromosomes 9 and 22. The resultant *BCR:ABL* fusion oncogene is associated with the development of abnormal myeloid proliferation and accumulation of immature granulocytes. The initial chronic phase (CP-CML) is marked by a myeloproliferative picture lasting months to years, which evolves into an advanced phase (AP-CML) characterized by poor response to therapy and worsening cytopenias; finally, this phase then evolves into a terminal blast phase (BP-CML), resulting in acute leukemia (70% myeloid and approximately 30% lymphoid subtype). The criteria for accelerated and blast phases of CML are described in Table 1.

SYNONYMS

Chronic granulocytic leukemia
Chronic myelogenous leukemia

ICD-10CM CODES

C92.10	Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
C92.11	Chronic myeloid leukemia, BCR/ABL-positive, in remission
C92.12	Chronic myeloid leukemia, BCR/ABL-positive, in relapse

EPIDEMIOLOGY & DEMOGRAPHICS

- CML usually presents in the mid-50s range and accounts for 15% to 20% of adult leukemias.
- Incidence is 1 to 1.5 cases per 100,000 people annually.
- In 2019, nearly 8990 new cases and more than 1140 deaths are estimated to occur in the U.S.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Up to 50% patients are asymptomatic, with diagnosis based on abnormal blood counts.
- In chronic phase, symptomatic patients have fatigue, weight loss, early satiety, and left abdomen pain, and the examination can reveal splenomegaly. Occasionally, hyperleukocytosis and severe thrombocytosis may lead to hyperviscosity-related symptoms.
- Patients in accelerated phase are usually symptomatic with fevers, sweats, weight loss, abdomen pain, and progressive splenomegaly.
- Patients in blast phase in addition can have bone pain; symptoms of anemia, infectious complications, and bleeding are also present.

ETIOLOGY

The etiology of CML is unclear, although radiation exposure has been linked in its development.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Splenic lymphoma
- Primary myelofibrosis
- Chronic neutrophilic leukemia
- Essential thrombocythemia

LABORATORY TESTS

- CBC showing left-shifted myeloid cells, with the presence of precursor polymorphonuclear cells, basophils, and eosinophils; can be accompanied by thrombocytosis and anemia.
- Bone marrow biopsy demonstrates hypercellularity with granulocytic hyperplasia, increased ratio of myeloid cells to erythroid cells, and increased megakaryocytes (Fig. E1).
- Bone marrow cytogenetics demonstrated the 9:22 translocation (Philadelphia chromosome) in >95% of patients (Fig. 2).
- Leukocyte alkaline phosphatase is markedly decreased (unlike other myeloproliferative disorders).
- *BCR-ABL* fusion transcripts can be measured using quantitative RT-PCR technology using either peripheral blood or bone marrow; serial peripheral blood monitoring of transcript level is utilized at 3-mo intervals to determine molecular remission status.

RISK STRATIFICATION

- Chronic phase CML patients can be stratified into low-, intermediate-, or high-risk criteria using the Sokal or Hasford criteria; more recently, the EUTOS score has been validated as an effective tool used to stratify patients into low- or high-risk categories.
- Patients developing secondary mutations have variable response to second- or third-line therapies; the *T315I* mutation is typically associated with resistance and is treated with allogeneic stem cell transplantation (SCT).

IMAGING STUDIES

Ultrasound or CT scan of abdomen can be done.

TREATMENT

Treatment with a potential to either cure CML or prolong long-term survival should be used according to the phase of the disease.

- Chronic phase: The therapeutic approach involves the use of either a first-generation (imatinib) or second-generation (dasatinib, nilotinib, or bosutinib) oral tyrosine kinase inhibitor (TKI). Imatinib mesylate, a 2-phenylaminopyrimidine derivative, binds to the canonic adenosine triphosphate (ATP)–binding site of the Abl kinase domain. It blocks phosphorylation of tyrosine residues on substrate protein. Blocking ATP binding inactivates the Abl kinase because it cannot transfer phosphate to its substrate. Inhibiting phosphorylation prevents activation of signal transduction pathways that cause CML (Fig. E3). Imatinib inhibits several tyrosine kinases, including $p210^{BCR–ABL1}$, $p190^{BCR–ABL1}$, v-ABL1, c-ABL1, c-Kit, and platelet-derived growth factor receptor (PDGFR). The decision to select a particular TKI is based on patient comorbidities, age, and often formulary restrictions. The large majority of patients obtain hematologic and cytogenetic remissions; major molecular

TABLE 1 Definitions of the Accelerated and Blastic Phases of Chronic Myeloid Leukemia

Criteria	MD Anderson Cancer Center[a]	International Bone Marrow Transplant Registry	World Health Organization
Accelerated Phase			
Percent blasts	15-29	10-29	10-19
Percent blasts + promyelocytes	≥30	≥20	NA
Percent basophils	≥20	≥20% (basophils + eosinophils)	≥20
Platelets ($\times 10^9$/L)	<100	Unresponsive ↑, persistent ↓	<100 or >1000 unresponsive
Cytogenetics	CE	CE	CE not at diagnosis
WBCs	NA	Difficult to control, or doubling in <5 days	NA
Anemia	NA	Unresponsive	NA
Splenomegaly	NA	Increasing	NA
Other		Chloromas, myelofibrosis	Megakaryocyte proliferation, fibrosis
Blastic Phase			
30% or more blasts; or extramedullary blastic disease, except for the World Health Organization classification, which requires 20% or more			

[a]These criteria were also used in all the IFN-α and tyrosine kinase inhibitor studies.
CE, Clonal evolution; *NA,* not applicable; *WBC,* white blood cell.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

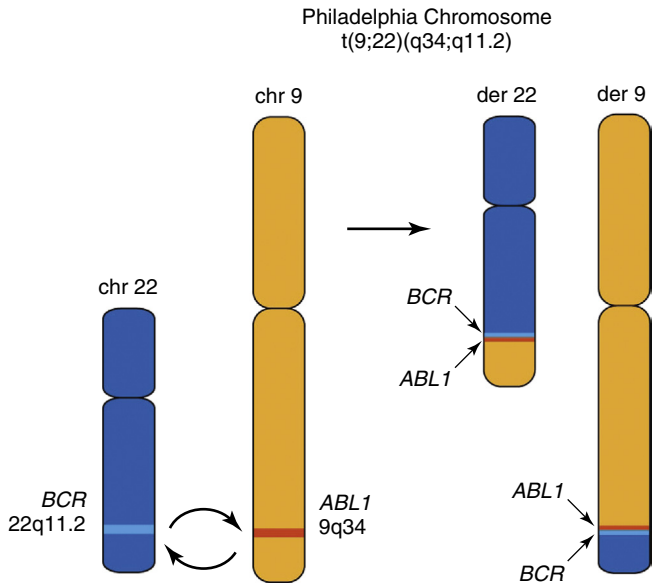

FIG. 2 The Philadelphia chromosome, der(22q), results from the reciprocal translocation of a portion of the *ABL1* gene on chromosome 9 at band q34 to the region of the *BCR* gene on chromosome 22 at band q11.2. In turn, a portion of *BCR* is translocated to chromosome 9 to the region of *ABL1*. In 5% to 10% of patients with chronic myeloid leukemia, cryptic or complex rearrangements result in a *BCR-ABL1* fusion gene, even though no Philadelphia chromosome is detected cytogenetically. (From Jaffe ES et al: *Hematopathology,* Philadelphia, 2011, WB Saunders.)

TABLE 2 Approved Indications in Chronic Myeloid Leukemia

	Frontline	Salvage	Accelerated	Blastic
Imatinib	400 mg QD 340 mg/m^2 per day	400 mg QD (IFN failure)	600 mg QD (IFN failure)	600 mg QD (IFN failure)
Dasatinib	100 mg QD	100 mg QD	140 mg QD	140 mg QD
		A	A	A
Nilotinib	300 mg BID	400 mg BID	400 mg BID	—
		A	A	
Bosutinib	—	500 mg QD	500 mg QD	500 mg QD
		B	B	B
Ponatinib	—	45 mg QD	45 mg QD	45 mg QD
		B	B	B
Omacetaxine	—	1.25 mg/m^2 SC × 14 days every 28 days (induction), then × 7 days every 28 days	1.25 mg/m^2 SC × 14 days every 28 days (induction), then × 7 days every 28 days	—
		C	C	

A, Resistance or intolerance to prior therapies including imatinib; *B,* resistance or intolerance to prior tyrosine kinase inhibitors (TKIs); *BID,* twice daily; *C,* resistance or intolerance to two prior TKIs; *IFN,* interferon; *QD,* daily; *SC,* subcutaneously.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

remissions are observed in 25% to 60% cases. Patients who lose their initial response, develop secondary mutations, or develop intolerance to therapy can be treated with newer third-generation TKIs (bosutinib, ponatinib). Omacetaxine, a protein synthesis inhibitor, is also effective in patients who have previously received TKI therapy. The approved indications are summarized in Table 2. An algorithm of the suggested treatment approach in CML is illustrated in Fig. 4.

- Second-generation TKIs (dasatinib, nilotinib, or bosutinib) are preferred for patients with an intermediate- or high-risk Sokal or Hasford score, especially for young women whose goal is to achieve a deep and rapid molecular response and eventual drug discontinuation of TKI therapy for fertility purposes.
- During therapy for chronic phase CML, treatment efficacy is monitored by the use of serial RT-PCR to measure peripheral blood *BCR-ABL* transcripts every 3 to 6 mo.
- Accelerated phase: Patients are initially treated with second-generation TKIs but ultimately require allogeneic SCT.
- Blast phase: Patients are initially treated with conventional induction chemotherapy as per the type of evolved acute leukemia and then subsequently undergo allogeneic SCT.
- Symptomatic hyperleukocytosis is treated with leukapheresis and hydroxyurea; allopurinol should be started to prevent urate nephropathy after the rapid lysis of the leukemia cells.

DISPOSITION

- Response definition and monitoring are summarized in Table 3.
- Median survival for patients with chronic phase CML undergoing therapy with current TKIs is estimated to last 25+ yr.
- Median survivals for patients with accelerated and blast phase CML are 5 yr and 7 to 11 mo, respectively.
- Discontinuing oral TKI therapy in chronic phase CML patients who have achieved deep molecular remissions is associated with molecular relapses in up to half the cases; as such, indefinite therapy is preferred in all cases.

REFERRAL

To hematology physician

PEARLS & CONSIDERATIONS

- Chronic-phase CML patients should be risk-stratified at diagnosis to define prognosis upfront; patients achieving complete cytogenetic remission or major molecular remission by 12 mo have consistently superior long-term outcomes.
- Regular monitoring of molecular response using peripheral blood RT-PCR for BCR:ABL transcript levels is done every 3 to 6 mo for disease monitoring.
- Allogeneic stem cell transplantation is a useful modality for advanced CML patients and chronic phase CML patients who develop resistance to standard TKI therapy.

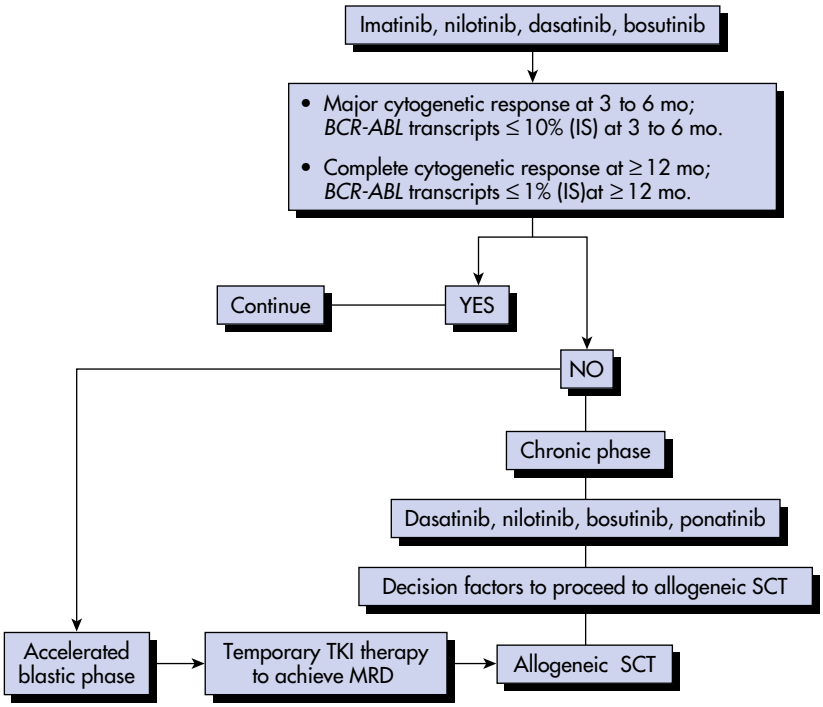
Chronic Myeloid Leukemia (Patient Information)

AUTHOR: **Ritesh Rathore, MD**



- Choice of salvage (TKI) depends on frontline TKI, and *BCR-ABL* mutation. If *T315I* mutation, only ponatinib is effective; if not available, use hydrea or chemotherapy, and proceed to allogeneic stem cell transplantation (SCT).

- In CML salvage the following are considered:
  - If relapse in accelerated-blastic phase, use TKIs as temporary measure to achieve minimal residual disease (MRD) and proceed to allogeneic SCT.
  - If relapse in chronic phase, choice of TKI based on mutations. Choice to continue on TKI indefinitely depends on presence of absence of clonal evolution, adverse mutations, and response to TKIs.
  - Older patients (≥65 yr) and patients with poor matching donors may decide to continue TKIs in combination with hydroxyurea or other chemotherapy to gain several years of good quality of life, rather than opt for allogeneic SCT.

FIG. 4 Algorithm of the suggested treatment approach in chronic myeloid leukemia (CML). *TKI,* Tyrosine kinase inhibitor. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

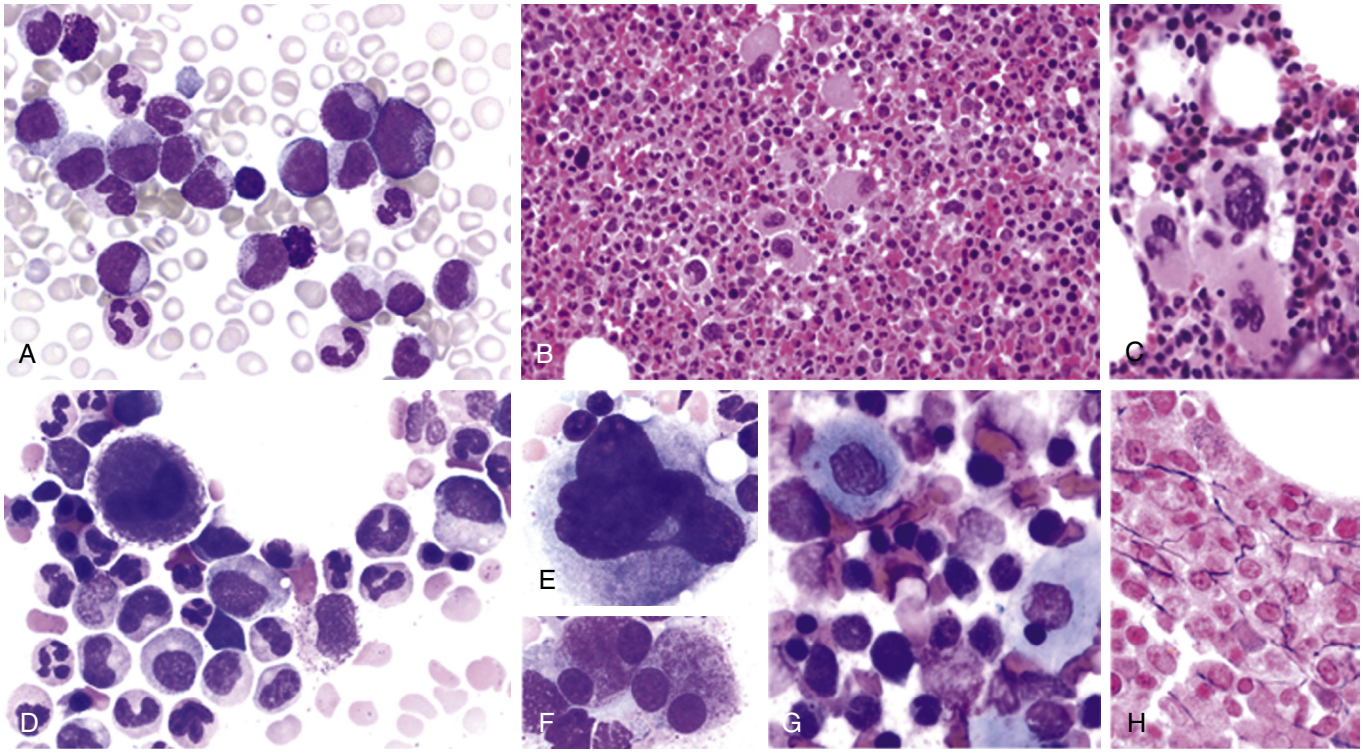

FIG. E1 Chronic myeloid leukemia, chronic phase. Peripheral smear **(A)** showing marked leukocytosis caused by a granulocytic proliferation of all stages with particularly increased myelocytes and absolute basophilia. Bone core biopsy **(B)** illustrating markedly hypercellular marrow caused by granulocytic proliferation and increased small hypolobated megakaryocytes. Compare with large megakaryocytes **(C)** from a myeloproliferative disorder other than chronic myeloid leukemia (CML). Bone marrow aspirate **(D)** showing granulocytic proliferation and small "dwarf" megakaryocyte, compared with large-size megakaryocyte **(E)** and micromegakaryocytes **(F)** typical of myelodysplastic syndrome (MDS). Pseudo-Gaucher cells **(G)** and mild fibrosis **(H)** as seen on reticulin stain. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Churchill Livingstone.)

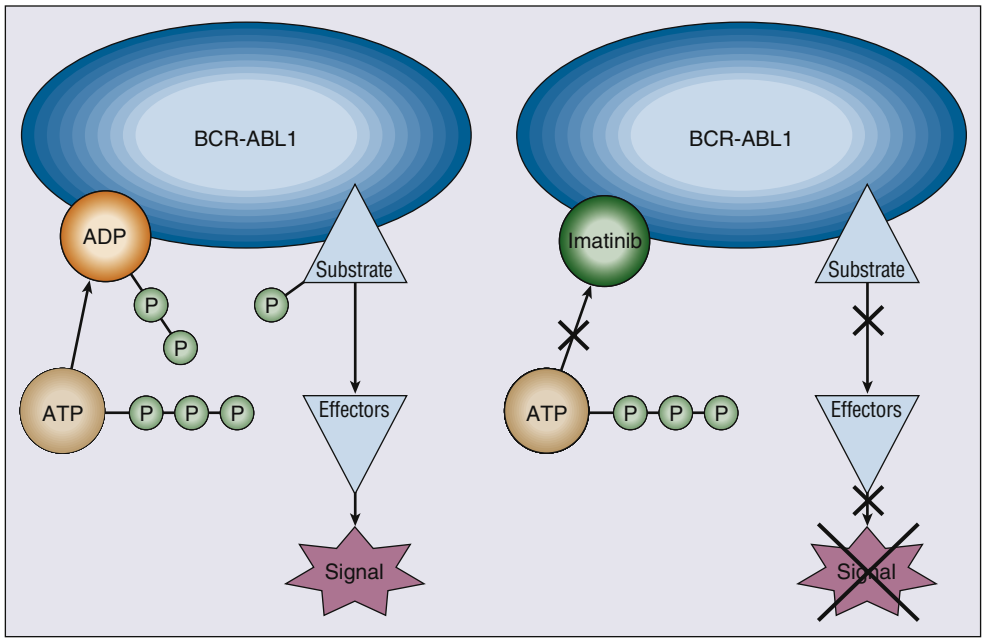

FIG. E3 The BCR-ABL1 oncoprotein has constitutive tyrosine kinase activity compared with the tightly regulated tyrosine kinase activity of the normal ABL1 product. The BCR-ABL1 kinase activates multiple substrates and binding partners, resulting in activation of downstream signaling pathways. This results in increased proliferation and reduced apoptosis of chronic myeloid leukemia (CML) cells. By binding to the ABL1 kinase domain, imatinib prevents the phosphorylation of BCR-ABL1, thus interrupting the activation of the CML pathways. *ADP,* Adenosine diphosphate; *ATP,* adenosine triphosphate. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

BASIC INFORMATION

DEFINITION

Chronic obstructive pulmonary disease (COPD) is an inflammatory respiratory disease usually caused by exposure to tobacco smoke. It is an umbrella term for various clinical entities with multiple causes resulting in airflow limitation that is not fully reversible. The pathophysiology of COPD is related to enhanced inflammatory response to noxious particles and gases, chronic airway irritation, mucus production, and pulmonary scarring and changes in pulmonary vasculature.

Acute exacerbations and comorbidities contribute to the overall severity and prognosis of the disease in individual patients.

Traditionally, COPD was described as encompassing *emphysema*, characterized by loss of lung elasticity and destruction of lung parenchyma with enlargement of air spaces, and *chronic bronchitis*, characterized by obstruction of small airways and productive cough >3 mo for more than 2 successive yrs. These terms are no longer included in the formal definition of COPD, although they are still used clinically. Although emphysema and chronic bronchitis are commonly associated with COPD, neither is required to make the diagnosis.

An overlap syndrome known as ACOS (asthma-COPD overlap syndrome), characterized by persistent airflow limitation with several features associated with asthma and several features associated with COPD, has been gaining recognition and may have treatment and mortality implications (Global Initiative for Chronic Obstructive Lung Disease [GOLD] and Global Initiative for Asthma [GINA] consensus statement).

SYNONYMS

COPD
Emphysema
Chronic bronchitis

ICD-10CM CODES

J42	Chronic bronchitis, unspecified chronic bronchitis type
J44.9	Chronic obstructive pulmonary disease, unspecified COPD type
J44.0	Chronic obstructive pulmonary disease with acute lower respiratory infection
J44.1	Chronic obstructive pulmonary disease with acute exacerbation
J43.0	Unilateral emphysema
J43.1	Panlobular emphysema
J43.2	Centrilobular emphysema
J43.8	Other emphysema
J43.9	Pulmonary emphysema, unspecified emphysema type

EPIDEMIOLOGY & DEMOGRAPHICS

- COPD affects 14% of U.S. adults aged 40 to 79 yr.
- Between 10% and 20% of COPD in the U.S. is due to occupational or other exposure to chemical vapors, irritants, and fumes; 80% to 90% is due to cigarette smoking.
- COPD is the third leading cause of death in the U.S.
- Highest incidence is in males >40 yr.
- 16 million office visits, 500,000 hospitalizations, 126,000 deaths annually, and >$18 billion in direct health care costs annually can be attributed to COPD.
- Patients with COPD living in isolated rural areas of the U.S. are at greater risk for COPD exacerbation-related mortality than those living in urban areas, independent of hospital rurality and volume.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with COPD have historically been classically subdivided in two major groups based on their phenotype:
  1. *Blue bloaters* are patients with chronic bronchitis; the name is derived from the bluish tinge of the skin (as a result of chronic hypoxemia and hypercapnia) and from the frequent presence of peripheral edema (from cor pulmonale); chronic cough with production of large amounts of sputum is characteristic.
  2. *Pink puffers* are patients with emphysema; they have a cachectic appearance but pink skin color (adequate oxygen saturation); shortness of breath is manifested by pursed-lip breathing and use of accessory muscles of respiration.
- COPD may present with combinations of the following signs and symptoms:
  1. Cyanosis, chronic cough (usually productive but may be intermittent and may be unproductive), tachypnea, tachycardia.
  2. Dyspnea (persistent, progressive), pursed-lip breathing with use of accessory muscles for respiration, decreased breath sounds, wheezing.
  3. Chronic sputum production.
  4. Chest wall abnormalities (hyperinflation, "barrel chest," protruding abdomen).
  5. Flattening of diaphragm.

TABLE 1 Systemic Manifestations and Comorbidities of COPD

Cardiovascular	Infarction Arrhythmia Congestive heart failure Aortic aneurysm
Hypercoagulability	Stroke Pulmonary embolism Deep vein thrombosis Atrophy
Systemic	Weight loss Osteoporosis Skin wrinkling Anemia Fluid retention
Lung cancer	Depression

From Mason RJ: *Murray & Nadel's textbook of respiratory medicine*, ed 5, Philadelphia, 2010, WB Saunders.

- Systemic manifestations and comorbidities of COPD are described in Table 1.
- Acute exacerbation of COPD is mainly a clinical diagnosis and generally manifests with worsening dyspnea, increase in sputum purulence, and increase in sputum volume. Respiratory symptom status, however, is not a reliable indicator of the presence of airflow obstruction. Individuals with normal spirometry values may report respiratory symptoms, whereas individuals who have severe to very severe airflow obstruction by spirometry may report no symptoms. Individuals with sedentary lifestyles may underestimate their symptoms and careful history taking is important to elicit symptoms suggestive of COPD.

ETIOLOGY

- Tobacco exposure (Fig. E1)
- Occupational exposure to pulmonary toxins (e.g., dust, noxious gases, vapors, fumes, cadmium, coal, silica); the industries with the highest exposure risk are plastics, leather, rubber, and textiles
- Atmospheric pollution
- Alpha-1-antitrypsin deficiency (rare; <1% of COPD patients)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Heart failure (HF)
- Asthma
- Tuberculosis, other respiratory infections
- Bronchiectasis
- Anemia
- Cystic fibrosis
- Neoplasm
- Pulmonary embolism
- Obliterative bronchiolitis
- Diffuse panbronchiolitis
- Sleep apnea, obstructive
- Hypothyroidism <50% predicted
- Neuromuscular disease

DIAGNOSTIC WORKUP

- Chest x-ray is seldom diagnostic but useful to visualize significant hyperinflation and to exclude alternative diagnosis (e.g., CHF, TB).
- Pulmonary function testing (spirometry). Spirometry is the reference standard for diagnosing and assessing the severity of COPD. Measurement of airflow limitation (by forced expiratory volume in 1 second [FEV_1]) is recommended to confirm diagnosis and establish prognosis.
- Oxygen saturation and arterial blood gases (useful in selected patients with FEV_1 <50% predicted, with acute exacerbation or hypoxia by pulse oximetry).
- Alpha-1-antitrypsin: All patients with COPD should be screened one time for alpha-1 antitrypsin deficiency.

LABORATORY TESTS

- CBC: Generally not helpful, may reveal leukocytosis with left shift during acute exacerbation and secondary polycythemia in COPD with significant, chronic hypoxia. Recent trials have

shown that eosinophilia in COPD patients predicts response to corticosteroids. Eosinophilia may also be found in an acute exacerbation in an asthma-COPD overlap syndrome.
- Sputum may be purulent with bacterial respiratory tract infections. Sputum staining and cultures are usually reserved for cases refractory to antibiotic therapy.
- Arterial blood gases: Normocapnia, mild to moderate hypoxemia may be present. ABGs and pulse oximetry are usually used to determine if a patient is a candidate for long-term oxygen therapy or if hypercapnia is present (ABGs).
- Spirometry pulmonary function testing (PFT) with measurement of forced vital capacity (FVC) and FEV_1. Spirometry should be obtained to diagnose airflow obstruction in clinically stable patients with respiratory symptoms. It should not be used to screen for airflow obstruction in individuals without respiratory symptoms. Spirometry reveals that the primary physiologic abnormality in COPD is an accelerated decline in FEV_1 from the normal rate in adults >30 yr of approximately 30 ml/yr to nearly 60 ml/yr. PFT results in COPD reveal abnormal diffusing capacity, increased total lung capacity and/or residual volume, and fixed reduction in FEV_1 in patients with emphysema; normal diffusing capacity and reduced FEV_1 are found in patients with chronic bronchitis. Stage and severity of COPD according to post-bronchodilator spirometry are described in Table 2. It is important to note that FEV_1 does not correlate well with individual patients' severity of dyspnea, exercise limitations, or health status. Evaluation of patients should also focus on symptom control and risk for adverse events in addition to FEV_1.
- Patients with COPD can generally be distinguished from asthmatics by their incomplete response to short-acting beta agonist (change in FEV_1 <200 ml and 12%) and absence of an abnormal bronchoconstrictor response to methacholine or other stimuli. Nearly 40% of patients with COPD will, however, respond to bronchodilators. Similarly, patients without a smoking history but with chronic asthmatic bronchitis may have airflow obstruction that is not completely reversible.

ASSESSMENT

The global initiative for chronic obstructive lung disease (GOLD) assigns patients with COPD into four groups (A, B, C, D) based on (1) the degree of airflow restriction (Table 2), (2) a patient symptom score using one of two symptom questionnaires (CAT or mMRC), or (3) the number of COPD exacerbations in 1 yr.[1]

IMAGING STUDIES

Chest x-ray:
- Hyperinflation with flattened diaphragm, tenting of the diaphragm at the rib, and increased retrosternal chest space (Fig. 2)
- Decreased vascular markings and bullae in patients with emphysema
- Thickened bronchial markings and enlarged right side of the heart in patients with chronic bronchitis
- Computed tomography: Emphysematous lung, tracheobronchomalacia

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Smoking cessation and elimination of air pollutants.
- Vaccination (pneumococcal vaccine and annual influenza vaccine).
- Supplemental oxygen, usually through a face mask/nasal cannula, to ensure oxygen saturation >90% as measured by pulse oximetry. Continuous oxygen therapy should be prescribed for patients with COPD who have arterial partial pressure of oxygen 55 mm Hg or less, or oxygen saturation 88% or less as measured by pulse oximetry. In patients with stable COPD and moderate resting desaturation (SpO2 89 to 93%) or moderate exercise-induced moderate desaturation (during the 6-minute walk test, Spo2 ≥80% for ≥5 minutes and <90% for ≥10 seconds), long-term supplemental oxygen did not improve mortality or time to first hospitalization.
- Pulmonary secretion clearance: Careful nasotracheal suction is indicated only in patients with excessive secretions and an inability to expectorate. Mechanical percussion of the chest as applied by a physical or respiratory therapist is ineffective with acute exacerbations of COPD.
- Pulmonary rehabilitation should be considered in COPD patients who remain symptomatic despite optimal medical management. Medicare will cover up to 36 sessions of pulmonary rehabilitation in COPD patients.
- Weight loss in obese patients.
- Identification of depression in patients newly diagnosed with COPD is important, as it may be associated with decreased adherence to maintenance therapy of COPD.
- Use of continuous positive airway pressure (CPAP) in patients with COPD and obstructive sleep apnea, as it improves both survival and reduces hospital admissions.

TABLE 2 Stage and Severity of COPD According to Postbronchodilator Spirometry

GOLD Stage and Severity	Definition
I: Mild	FEV_1/FVC <0.70, FEV_1 ≥80% of predicted
II: Moderate	FEV_1/FVC <0.70, 50% ≤ FEV_1 <80% of predicted
III: Severe	FEV_1/FVC <0.70, 30% ≤ FEV_1 <50% of predicted
IV: Very severe	FEV_1/FVC <0.70, FEV_1 <30% of predicted or FEV_1 <50% of predicted plus chronic respiratory failure

FEV_1, Forced expiratory volume in 1 s; *FVC,* forced vital capacity. Data from the Global Initiative for Chronic Obstructive Lung Disease, 2017 Report.

GENERAL Rx

- Pharmacologic treatment should be administered in a stepwise approach according to the severity of disease and patient's

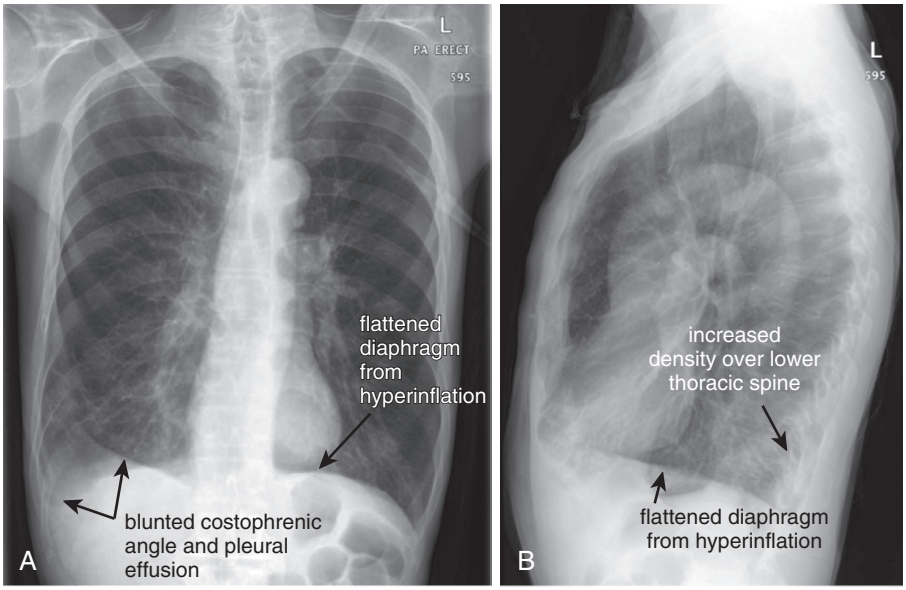

FIG. 2 Chronic obstructive pulmonary disease (COPD). A, Posterior-anterior (PA) upright chest x-ray. **B,** Lateral upright chest x-ray. This 63-yr-old man with a history of COPD presented with 2 wk of worsening cough with yellow sputum and dyspnea. His oxygen saturation was 87% in the emergency room. He has evidence of hyperinflation with flat diaphragms (particularly evident on the lateral x-ray) **(B).** The patient also has a blunted right costophrenic angle with an apparent effusion and increased densities in both the right and the left lung base **(A).** The lateral x-ray also shows increased density overlying the inferior thoracic spine, an abnormal spine sign. (From Broder JS: *Diagnostic imaging for the emergency physician*, Philadelphia, 2011, WB Saunders.)

[1] Lee H et al: Treatment of stable chronic obstructive pulmonary disease: the GOLD guidelines, *Am Fam Physician* 88(10):655-663, 2013.

tolerance for specific drugs. When using the GOLD assessment criteria, pulmonary rehabilitation is recommended for patients in groups B, C, and D. Those in group A should receive a short-acting or long-acting anticholinergic or β_2-agonist for mild intermittent symptoms. For patients in group B, long-acting anticholinergics or long-acting β_2-agonists should be added, and both if symptoms persist on one drug. Patients in group C or D are at high risk of exacerbations and should receive a long-acting anticholinergic or a combination of either an inhaled corticosteroid and a long-acting β_2-agonist or a long-acting anticholinergic and long-acting bronchodilator if symptoms persist. Patients in group D are more complicated and require individual management, multiple drugs, and consideration of roflumilast and azithromycin.

1. Bronchodilators improve symptoms, quality of life, and exercise tolerance and decrease incidence of exacerbations. Inhaled bronchodilators *should be offered* for stable COPD patients with respiratory symptoms and FEV[1] between 60% and 80% of predicted. Long-acting bronchodilators are *recommended* for stable COPD patients with respiratory symptoms and FEV_1 <60% of predicted. Recent guidelines from ACP, ACCP, ATS, and ERS recommend that clinicians prescribe monotherapy using either long-acting inhaled anticholinergics or long-acting inhaled β-agonists for symptomatic patients with COPD and FEV_1 <60% of predicted. Clinicians should base the choice of specific monotherapy on patient preference, cost, and adverse effect profile. Long-acting inhaled bronchodilators are superior to short-acting bronchodilators when taken as needed.
2. Short-acting β_2-agonists (e.g., albuterol metered-dose inhaler 1 to 2 puffs q4 to 6h prn) or short-acting anticholinergic agents (e.g., ipratropium inhaler 2 puffs qid) are acceptable in patients with mild, variable symptoms. Anticholinergics (antimuscarinic agents) are also effective and are available in combination with albuterol (e.g., Combivent). Long-acting inhaled agents (long-acting antimuscarinic agents [LAMAs]) are preferred in patients with mild to moderate or continuous symptoms. Currently available inhaled LAMAs are tiotropium (Spiriva), aclidinium (Tudorza), and glycopyrrolate (Seebri Neohaler, Yupelri). Tiotropium is an excellent long-acting bronchodilator. It is very effective for long-term, once-a-day use. It has been shown to be superior to salmeterol, an inhaled long-acting β-agonist (LABA) in patients with moderate to severe COPD and may possibly slow the rate of decline in FEV_1. Some recent trials, however, have shown higher hospitalization rates and mortality with tiotropium compared to LABAs. Indacaterol, umeclidinium, olodaterol, and vilanterol are other available LABAs for long-term maintenance treatment of bronchospasm associated with COPD. LABAs should not be used with other sympathomimetic drugs, medications that can prolong the QT interval, or beta-blockers. LABAs and LAMAs in different combinations are now available on the market. Although LAMAs and LABAs perform equally well for symptom control, LAMAs are generally preferred for symptom control.
3. Addition of inhaled steroids (fluticasone, budesonide, triamcinolone) is used to reduce exacerbations in patients with moderate to severe COPD. Inhaled steroids are reserved for patients with either ≥2 exacerbations annually or FEV_1 <50% of predicted. The role of inhaled corticosteroids (ICS) in COPD is controversial. Although some trials have demonstrated mild improvement in patients' symptoms and decreased frequency of exacerbations, most pulmonologists believe that these drugs are ineffective in most patients with COPD but should be considered for patients with moderate to severe airflow limitation who have persistent symptoms despite optimal bronchodilator therapy. ICS therapy does not affect 1-yr all-cause mortality among patients with COPD and is associated with a higher risk of pneumonia.
4. Roflumilast is a selective oral PDE4 inhibitor useful to reduce the risk of COPD exacerbations in patients with severe COPD associated with chronic bronchitis and a history of exacerbations. It is not a bronchodilator and is not indicated for the relief of acute bronchospasm.
5. Recent guidelines from ACP (American College of Physicians), ACCP (American College of Chest Physicians), ATS (American Thoracic Society), and ERS (European Respiratory Society) suggest that clinicians may administer combination inhaled therapies for symptomatic patients with stable COPD and FEV_1 <60% predicted. They also recommend that clinicians should prescribe pulmonary rehabilitation for symptomatic patients with an FEV_1 <50% predicted and continuous oxygen therapy in patients with COPD who have resting hypoxemia (Pa_{O_2} <55 mm Hg or Sp_{O_2} <88%).
6. Chronic antibiotic therapy: Chronic antibiotic therapy, specifically macrolide such as azithromycin, should be considered in patients with frequent acute exacerbations of COPD despite optimal therapy with bronchodilators and antiinflammatory agents.
7. Systemic glucocorticoid therapy: Chronic systemic glucocorticoid therapy is generally not recommended even in severe COPD due to associated increase in mortality and morbidity.
8. Triple therapy (LAMA plus LABA plus ICS [e.g., vilanterol, umeclidinium, and fluticasone {Trelegy Ellipta}]): Indicated in patients with COPD at high risk for exacerbations. A double-blind, parallel group, RCT (TRINITY) reported that treatment with extrafine fixed triple therapy reduced rates of moderate-to-severe exacerbation and improved baseline FEV_1 at 52 wk as compared with tiotropium in patients with symptomatic COPD, FEV_1 <50%, and a history of exacerbations. Another double-blind RCT (FULFIL) reported similar benefits of single-inhaler triple therapy compared with ICS/LABA therapy in patients with advanced COPD. The greatest benefit occurs in patients with eosinophilia or concomitant asthma. Unfortunately, many patients start triple therapy without clear indications and continue it after they no longer need it.

- Acute exacerbation of COPD (increase in sputum volume and purulence, worsening dyspnea) can be treated with:
  1. Aerosolized β_2-agonists (e.g., metaproterenol nebulizer solution 5% 0.3 ml or albuterol nebulized 5% solution 2.5 to 5 mg).
  2. Anticholinergic agents, which have equivalent efficacy to inhaled beta-adrenergic agonists. Inhalant solution of ipratropium bromide 0.5 mg can be administered every 4 to 8 hr.
  3. Short courses of systemic corticosteroids have been shown to improve spirometric and clinical outcomes. Treatment failure occurs less often in patients who receive low-dose steroids than in those receiving high-dose parenteral steroids. Oral prednisone 40 mg/day for 5 to 14 days is generally effective. Courses of treatment that are extended for >14 days confer no added benefit and increase the risk of adverse events. Trials have shown that in patients with acute COPD exacerbations, systemic glucocorticoid treatment for 5 days is not inferior to treatment for 14 days.
  4. Use of noninvasive positive pressure ventilation (NIPPV) decreases the risk of endotracheal intubation and decreases intensive care unit admission rates. Contraindications to its use are uncooperative patient, decreased level of consciousness, hemodynamic instability, inadequate mask fit, and severe respiratory acidosis. Increased airway pressure can be delivered by using inspiratory positive airway pressure, continuous positive airway pressure, or bilevel positive airway pressure, which combines the other modalities. When using NIPPV, the nasal mask is usually tolerated the best; however, patients must be instructed to keep their mouths closed while breathing with the nasal apparatus. Oxygen can be delivered at 10 to 15 L/min and started in spontaneous ventilation mode with an initial expiratory positive airway pressure setting of 3 to 5 cm H_2O and an inspiratory positive airway pressure setting of up

to 10 cm H_2O. Adjustments in these settings should be made in 2-cm H_2O increments. It is important to monitor patients with frequent vital signs measurements, arterial blood gases, or pulse oximetry. Intubation and mechanical ventilation may be necessary if previous measures fail to provide improvement.

5. IV aminophylline administration is controversial and generally not recommended. When used in patients with refractory symptoms, serum levels should be closely monitored (keep level 8 to 12 mcg/ml) to minimize risks of tachyarrhythmias.

- Approximately 50% of COPD exacerbations are caused by bacterial infection. Antibiotics are indicated in suspected bacterial respiratory infection (e.g., increased purulence and volume of phlegm).
  1. *Haemophilus influenzae* and *Streptococcus pneumoniae* are frequent causes of acute bronchitis.
  2. Oral antibiotics of choice are azithromycin, levofloxacin, amoxicillin-clavulanate, trimethoprim-sulfamethoxazole, doxycycline, and cefuroxime.
  3. The two best predictors of potential benefit from antibiotics are purulent sputum and C-reactive protein (CRP) level >40 mg/L.
  4. Procalcitonin-based protocols to trigger antibiotic use are associated with significantly decreased antibiotic use without affecting clinical outcomes such hospital length of stay, treatment failure, and mortality.
- Guaifenesin may improve cough symptoms and mucus clearance; however, mucolytic medications are generally ineffective. Their benefits may be greatest in patients with more advanced disease.
- Fig. 3 illustrates the management of acute exacerbations of COPD. Guideline recommendations for hospital management of COPD exacerbations are described in Table 3. Indications for invasive mechanical ventilation are described in Box 1.
- Lung volume reduction surgery has been proposed as a palliative treatment for severe emphysema. Overall it increases the chance of improved exercise capacity but does not confer a survival advantage over medical therapy. It is most beneficial in patients with both predominantly upper-lobe emphysema and low baseline exercise capacity.
- Preliminary trials involving lung volume reduction using bronchoscopic treatment with nitinol coils have shown improved exercise capacity in patients with severe emphysema. Selection criteria for lung volume reduction surgery is described in Table 4. Box 2 summarizes indications and contraindications for lung volume reduction surgery and lung transplantation.
- Endobronchial valve (EBV) placement (Zephyr valve) via bronchoscopy to reduce lung volume with one-way valves that are allowed to leave but not enter a lung segment is now FDA approved since June 2018.
- Single-lung transplantation (Box 2) should be considered a surgical option in patients with end-stage emphysema who have an FEV_1 <25% of predicted normal value after administration of bronchodilator and additional complications such as severe hypoxemia, hypercapnia, and pulmonary hypertension.

DISPOSITION

- After the initial episode of respiratory failure, 5-yr survival is approximately 25%.
- Development of cor pulmonale or hypercapnia and persistent tachycardia are poor prognostic indicators.
- Supplemental oxygen for patients with resting hypoxemia (defined as SPO_2 <89%) improves survival. The need for oxygen at rest may be the strongest predictor of mortality in chronic respiratory failure from COPD.
- Pulmonary rehabilitation, which includes strength and endurance training and education, nutritional, and psychosocial support, improves symptoms and exercise tolerance but is underutilized.[1]

PEARLS & CONSIDERATIONS

COMMENTS

- All patients with COPD should receive pneumococcal vaccine and yearly influenza vaccine.
- Early antibiotic administration is associated with improved outcomes among patients hospitalized for acute exacerbations of COPD regardless of the risk of treatment failure.
- In assessing the severity of COPD, the FEV_1 is limited by the fact that it does not take into account the systemic manifestations of COPD. The BODE index (body mass index, degree of obstruction, dyspnea, and exercise capacity) has been proposed as a multidimensional scale to better assess the morbidity and mortality associated with COPD. It is better than the FEV_1 alone at predicting the risk of death from any cause and from respiratory causes among patients with COPD. In the BODE index, obstruction is measured by FEV_1 and dyspnea is measured by the modified Medical Research Council (MMRC) dyspnea questionnaire in a 6-minute walk test. A score of 0 on the MMRC indicates that the individual is not troubled with breathlessness except with strenuous exercise, 1 indicates shortness of breath when hurrying or walking up a slight hill, and 2 means the individual walks slower than people of the same age due to breathlessness or has to stop for breath when walking at own pace on level ground. A score of 3 means severe dyspnea because the person has to stop for breath after walking approximately 100 meters or after a few minutes on level ground, and a score of 4 indicates very severe dyspnea and is given when the individual is too breathless to leave the house or is breathless when dressing or undressing.
- Pulmonary artery enlargement as determined by a ratio of the diameter of the pulmonary artery to the diameter of the aorta [PA:A ratio] of >1 detected by CT is associated with severe exacerbations of COPD.
- The average person with COPD has one or two acute exacerbations each yr. Prophylactic use of macrolide antibiotics (azithromycin 250 mg/day) has been shown to decrease the frequency of exacerbations and improve quality of life among selected patients with COPD; however, it leads to hearing decrements in a small percentage of patients and increased prevalence of macrolide-resistant bacteria colonizing the airway and is therefore not recommended.
- Eosinophilic airway inflammation may contribute to COPD exacerbations. Patients with COPD with eosinophilic phenotype may benefit from mepolizumab, a monoclonal antibody directed against interleukin-5.
- Current and former smokers (within 15 yr) with at least a 30-pack-yr history of smoking should be assessed for lung cancer using low-dose computed tomography.

TABLE 3 Guideline Recommendations for Hospital Management of COPD Exacerbations

	Global Initiative for Chronic Obstructive Lung Disease*	American Thoracic Society/ European Respiratory Society†	National Institute for Clinical Excellence‡
Date of statement	2017	2017	2010
Diagnostic testing	Chest radiograph, oximetry, ABGs, ECG. Other testing as warranted by clinical indication.	Chest radiograph, oxygen saturation, ABGs, ECG, sputum Gram stain and culture.	Chest radiograph, ABG, ECG, complete blood count, sputum smear and culture, blood cultures if febrile.
Bronchodilator therapy	Inhaled short-acting β_2-agonist is recommended. Consider ipratropium if inadequate clinical response. Methylxanthines are not recommended due to increased side effect profiles.	Inhaled short-acting β_2-agonist and/or ipratropium with spacer or nebulizer, as needed.	Administer inhaled drugs by nebulizer or handheld inhaler. Specific agents and dosing regimens not specified. Consider theophylline if inadequate response to inhaled bronchodilators.
Antibiotics	Recommended if (1) increases in dyspnea, sputum volume, and sputum purulence all are present; (2) increase in sputum purulence along with increase in either dyspnea or sputum volume; or (3) need for assisted ventilation. See original document for complex treatment algorithm.	Base choice on local bacterial resistance patterns. Consider amoxicillin/clavulanate or respiratory fluoroquinolones. If *Pseudomonas* species and/or other Enterobacteriaceae are suspected, consider combination therapy.	Administer only if history of purulent sputum. Initiate with an aminopenicillin, a macrolide, or a tetracycline, taking into account local bacterial resistance patterns. Adjust therapy according to sputum and blood cultures.
Systemic corticosteroids	Daily prednisolone 30-40 mg (or its equivalent) orally for not more than 5-7 days.	Daily prednisone 30-40 mg orally for 10-14 days. Equivalent dose intravenously if unable to tolerate oral intake. Consider inhaled corticosteroids.	Daily prednisolone 30 mg (or its equivalent) orally for 7-14 days.
Supplemental oxygen	Maintain oxygen saturation >90%. Monitor ABGs for hypercapnia and acidosis.	Maintain oxygen saturation >90%. Monitor ABGs for hypercapnia and acidosis.	Maintain oxygen saturation within the individualized target range. Monitor ABGs.
Assisted ventilation	Indications for NPPV include severe dyspnea, acidosis (pH ≤7.35) and/or hypercapnia (PCO_2 >45 mm Hg), and respiratory rate >25 breaths/min. Contraindications to NPPV include respiratory arrest, hemodynamic instability, impaired mental status, copious bronchial secretions, and extreme obesity. Intubate if contraindication to NPPV or failure of NPPV (worsening ABGs or clinical status). Consider likelihood of recovery and patient's wishes and expectations before intubation.	Consider with pH <7.35 and PCO_2 >45-60 mm Hg and respiratory rate >24 breaths/min. Institute NPPV in a controlled environment, unless there are contraindications (e.g., respiratory arrest, hemodynamic instability, impaired mental status, copious bronchial secretions, and extreme obesity). Intubate if contraindication to NPPV or failure of NPPV (worsening ABGs or clinical status).	NPPV treatment of choice for persistent hypercapnic respiratory failure. Consider functional status, body mass index, home oxygen, comorbidities, prior ICU admissions, age, and FEV_1 when assessing suitability for intubation and ventilation.

ABGs, Arterial blood gases; *ECG,* electrocardiogram; *FEV_1,* forced expiratory volume in 1 s; *ICU,* intensive care unit; *PCO2,* partial pressure of carbon dioxide; *NPPV,* noninvasive positive pressure ventilation.

BOX 1 Indications for Invasive Mechanical Ventilation

Severe dyspnea, with use of accessory muscles and paradoxical abdominal motion
Respiratory frequency >35 breaths/min
Life-threatening hypoxemia (Pao_2 <40 mm Hg or Pao_2/Fio_2 <200 mm Hg)
Severe acidosis (pH <7.25) and hypercapnia ($Paco_2$ >60 mm Hg)
Respiratory arrest
Somnolence, impaired mental status
Cardiovascular complications (hypotension, shock, heart failure)
Other complications: Metabolic abnormalities, sepsis, pneumonia, pulmonary embolism, barotrauma, massive pleural effusion
Noninvasive positive-pressure ventilation failure (or exclusion criteria)

Fio_2, Inspired oxygen fraction; $Paco_2$, partial pressure of carbon dioxide in arterial blood; *Pao_2,* partial pressure of oxygen in arterial blood.
From Vincent JL et al: *Textbook of critical care*, ed 6, Philadelphia, 2011, WB Saunders.

TABLE 4 Selection Criteria for Lung Volume Reduction Surgery

Inclusion Criteria	Exclusion Criteria
General	
Disability despite maximal rehabilitation	Inability to participate in rehabilitation
Cessation of tobacco use >6 mo	Continued use of tobacco
Patient´s expectation of goals reasonable	Significant comorbidity
	Previous pleurodesis or thoracotomy
	Underweight, overweight
Anatomic-Radiographic Evaluation	
Marked emphysema	Bronchiectasis
	Minimal radiographic emphysema
Heterogeneously distributed emphysema	Homogeneously distributed emphysema
Target zones of poorly perfused lung	No target zones
Areas with better preserved lung	No preserved lung tissue
Marked thoracic hyperinflation	Chest wall or thoracic cage abnormalities
Physiologic Evaluation	
Marked airflow obstruction	Minimal to moderate airflow obstruction
Marked hyperinflation	Minimal to moderate thoracic hyperinflation
Alveolar gas exchange	Markedly disordered alveolar gas exchange
DL_{co} <50% (steady state)	DL_{co} <10%
	$Paco_2$ >60 mm Hg
Cardiovascular function	Cardiovascular function
Essentially normal ejection fraction	Mean pulmonary artery pressure >35 mm Hg
	Left ventricular ejection fraction <40%
	Significant coronary artery disease

DL_{co}, Diffusing capacity of the lungs for carbon monoxide; *$Paco_2$*, partial pressure of carbon dioxide in arterial blood.
From Sellke FW et al: *Sabiston & Spencer surgery of the chest*, ed 9, Philadelphia, 2016, Elsevier.

BOX 2 Indications and Contraindications for Lung Volume Reduction Surgery and Lung Transplantation

Indications Common to Both Procedures
Emphysema with destruction and hyperinflation
Marked impairment (FEV_1 <35% predicted)
Marked restriction in activities of daily living
Failure of maximal medical treatment to correct symptoms

Contraindications to Both Procedures
Abnormal body weight (<70% or >130% of ideal)
Coexisting major medical problems increasing surgical risk
Inability or unwillingness to participate in pulmonary rehabilitation
Unwillingness to accept the risk of morbidity and mortality of surgery
Tobacco use within the past 6 mo
Recent or current diagnosis of malignant disease
Increasing age (>65 yr for transplantation, >70 yr for volume reduction)
Psychological instability, such as depression or anxiety disorder

Discriminating Conditions Favoring Lung Volume Reduction Surgery
Marked thoracic distention
Heterogeneous disease with obvious apical target areas
FEV_1 >20% predicted
Age between 60 and 70 yr

Discriminating Conditions Favoring Lung Transplantation
Diffuse disease without target areas
FEV_1 <20% predicted
Hypercapnia with $Paco_2$ >55 mm Hg
Pulmonary hypertension
Age younger than 60 yr
α_1-Antitrypsin deficiency

FEV_1, Forced expiratory volume in 1 s.
From Sellke FW et al: *Sabiston & Spencer surgery of the chest*, ed 9, Philadelphia, 2016, Elsevier.

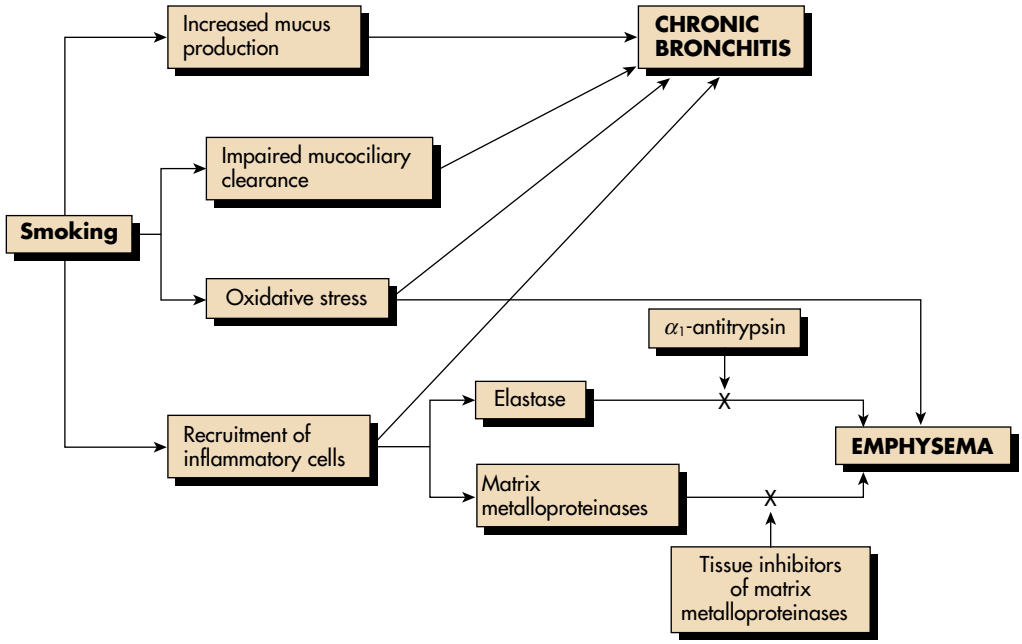

FIG. E1 Schematic diagram of the effect of smoking on airway inflammation and structural components of alveolar walls—the latter by altering the relationship between elastase and α1-antitrypsin (also called α1-protease inhibitor). BASIC INFORMATION

DEFINITION

Chronic pancreatitis is a recurrent or persistent inflammatory process of the pancreas characterized by chronic pain and by pancreatic exocrine and/or endocrine insufficiency. It is classified anatomically as either large-duct disease or small-duct (minimal change) disease.

ICD-10CM CODES

K86.1	Other chronic pancreatitis
K86.0	Alcohol-induced chronic pancreatitis

EPIDEMIOLOGY & DEMOGRAPHICS

- Chronic pancreatitis occurs in approximately five to 10 per 100,000 persons in industrialized countries.
- Average age at diagnosis is 35 to 55 yr; male:female ratio is 5:1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Persistent or recurrent epigastric and left upper quadrant pain that may radiate to the back
- Tenderness over the pancreas, muscle guarding
- Significant weight loss
- Bulky, foul-smelling stools, greasy in appearance
- Epigastric mass (10% of patients)
- Jaundice (5% to 10% of patients)

ETIOLOGY

- Chronic alcoholism (most common cause)
- Obstruction (ampullary stenosis, tumor, trauma [with pancreatic duct stricture], pancreas divisum, annular pancreas)
- Tobacco
- Recurrent pancreatitis
- Vascular disease/ischemia
- Hypertriglyceridemia
- Chronic kidney disease
- Hereditary pancreatitis
- Severe malnutrition
- Idiopathic
- Untreated hyperparathyroidism (hypercalcemia)
- Mutations of the cystic fibrosis transmembrane conductance regulator *(CFTR)* gene and the TF genotype
- Other genetic mutations (Cationic trypsinogen gene, chymotrypsinogen C gene, calcium-sensing receptor gene, claudin-2 gene, serine protease inhibitor, Kazal type 1 gene)
- ***Autoimmune pancreatitis (AIP):*** (5% of chronic pancreatitis cases): Presents clinically with jaundice (63% of patients) and abdominal pain (35%). CT may reveal diffusely enlarged pancreas, enhanced peripheral rim of hypoattenuation "halo," and low-attenuation mass in head of pancreas. Laboratory values reveal elevated serum immunoglobulin (Ig) G4, elevated serum Ig or gamma-globulin level, presence of antilactoferrin antibody (ALA), anticarbonic anhydrase (ACA) II level, anti–smooth-muscle antibody (ASMA), or antinuclear antibody (ANA)
- ***Sclerosing pancreatitis:*** A form of chronic pancreatitis characterized by infrequent attacks of abdominal pain, irregular narrowing of the pancreatic duct, and swelling of the pancreatic parenchyma; patients have high levels of serum immunoglobulins (IgG4); chronic sclerosing pancreatitis is also known as *autoimmune pancreatitis*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pancreatic cancer
- Peptic ulcer disease
- Cholelithiasis with biliary obstruction
- Malabsorption from other etiologies
- Recurrent acute pancreatitis
- Renal insufficiency
- Intestinal ischemia or infarction
- Other: Crohn disease, gastroparesis, inflammatory bowel disease

WORKUP

Medical history with focus on alcohol use, laboratory tests, diagnostic imaging. Table 1 summarizes available diagnostic tests for chronic pancreatitis.

TABLE 1 Available Diagnostic Tests for Chronic Pancreatitis

Tests of Pancreatic Structure	Tests of Pancreatic Function
EUS	Direct hormonal stimulation (with pancreatic stimulation by secretin or CCK or both): Using oroduodenal tube* Using endoscopy*
MRI with MRCP, with or without secretin stimulation	Fecal elastase
CT	Serum trypsinogen (trypsin)
ERCP	Fecal chymotrypsin
Abdominal US	Fecal fat
Plain abdominal film	Blood glucose level

*See text for explanations.
Tests are listed in estimated order of decreasing sensitivity for each category.
CT, Computed tomography; *ERCP,* endoscopic retrograde cholangiopancreatography; *EUS,* endoscopic ultrasonography; *MRCP,* magnetic resonance cholangiopancreatography; *MRI,* magnetic resonance imaging.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

LABORATORY TESTS

- Serum amylase and lipase may be elevated (normal amylase levels, however, do not exclude the diagnosis).
- Hyperglycemia, glycosuria, hyperbilirubinemia, and elevated serum alkaline phosphatase may also be present.
- 72-hr fecal fat determination (rarely performed) reveals excess fecal fat. Fecal elastase test requires only 20 g of stool.
- Secretin stimulation test is the best test for diagnosing pancreatic exocrine insufficiency. Pancreatic secretory function tests are summarized in Table 2.
- Lipid panel: Significantly elevated triglycerides can cause pancreatitis.
- Serum calcium: Hyperparathyroidism is a rare cause of chronic pancreatitis.
- Elevated levels of serum IgG4 are found in sclerosing pancreatitis and AIP.
- Elevated serum Ig or gamma-globulin level, presence of ALA, ACA II level, ASMA, or ANA in AIP.

IMAGING STUDIES

- Plain abdominal radiographs may reveal pancreatic calcifications in 25% of patients (95% specific for chronic pancreatitis).
- Ultrasound of abdomen may reveal duct dilation, pseudocyst, calcification, and presence of ascites.
- Contrast-enhanced CT scan of abdomen is the initial modality of choice. It is useful to detect calcifications (Fig. E1), evaluate for ductal dilation (Fig. E2), AIP, and rule out pancreatic cancer. CT in AIP reveals narrowed main pancreatic duct and a homogenous "sausage-shaped" pancreas.
- Endoscopic retrograde cholangiopancreatography (ERCP) (Fig. E3) had been traditionally used to evaluate for the presence of dilated ducts, strictures, pseudocysts, and intraductal stones. However, for the evaluation of pancreatic parenchyma and duct system newer, less invasive modalities such as magnetic resonance cholangiopancreatography and endoscopic ultrasonography (EUS) are preferred. EUS (Fig. E4) has a sensitivity of 97% and a specificity of 60% for chronic pancreatitis and a very low complication rate. The diagnosis of chronic pancreatitis on EUS is summarized in Table E3. Fine-needle aspiration biopsy combined with EUS is the preferred modality for evaluation of cystic or mass lesions to determine malignancy.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of alcohol and tobacco
- Frequent, small-volume, low-fat meals

ACUTE GENERAL Rx

- Avoidance of narcotics if possible (simple analgesics or NSAIDs can be used). Fig. 5 describes an approach to the patient with painful chronic pancreatitis. Management of chronic pancreatitis focuses on treatment of symptoms.
- Treatment of steatorrhea with pancreatic supplements (e.g., Pancrease, Creon, pancrelipase titrated prn based on the amount of steatorrhea and patient's weight loss). Enzyme products for the treatment of chronic pancreatitis are summarized in Table 4. All non–enteric-coated enzymes should be used with acid-suppressing

TABLE 2 Pancreatic Secretory Function Tests

Test	Description	Advantages	Disadvantages	Clinical Indications
Direct				
Secretin	Measurements of volume and HCO_3– secretion into the duodenum after IV secretin	Provide the most sensitive and specific measurements of exocrine pancreatic function	Require duodenal intubation and IV administration of hormones; not widely available	Detection of mild, moderate, or severe exocrine pancreatic dysfunction
CCK	Measurements of duodenal outputs of amylase, trypsin, chymotrypsin, and/or lipase after IV CCK			
Secretin and CCK	Measurements of volume, HCO_3–, and enzymes after IV secretin and CCK			
Indirect (Requiring Duodenal Intubation)				
Lundh test meal	Measurement of duodenal trypsin concentration after oral ingestion of a test meal	Does not require IV administration of hormones	Requires duodenal intubation, a test meal, and normal anatomy, including small intestinal mucosa; not widely available	Detection of moderate or severe exocrine pancreatic dysfunction when a direct test cannot be done (e.g., due to limited availability)
Indirect (Tubeless)				
Fecal fat	Measurement of fat in the stool after ingesting meals with a known amount of fat	Provides a quantitative measurement of steatorrhea	Requires sufficient dietary fat intake and collection of stool; only detects severe pancreatic dysfunction	Detection of severe exocrine pancreatic dysfunction and steatorrhea
Fecal chymotrypsin	Measurement of chymotrypsin or elastase 1 in the stool	Do not require IVs, tubes, or administration of oral substrates	Insensitive for detecting mild or moderate dysfunction	Detection of severe exocrine pancreatic dysfunction
Fecal elastase 1				
NBT-PABA	Oral ingestion of NBT-PABA or fluorescein dilaurate with a meal, followed by measurements of PABA or fluorescein in serum or urine	Provide simple measurements for severe pancreatic dysfunction	Do not detect mild or moderate dysfunction; results may be abnormal in patients with small intestinal mucosal disease	Detection of severe exocrine pancreatic dysfunction
Fluorescein dilaurate				

CCK, Cholecystokinin; *IV,* intravenous; *NBT-PABA, N*-benzoyl-L-tyrosyl-*p*-aminobenzoic acid.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

medications. Proton pump inhibitors and H_2 blockers reduce inactivation of the enzymes from gastric acid.
- Antioxidants (vitamin A, selenium, vitamin E) may be helpful for pain control in chronic pancreatitis.
- Percutaneous or via EUS celiac plexus blockade with corticosteroids or neurolysis with ethanol may provide temporary pain relief.
- Treatment of complications (e.g., type 1 diabetes mellitus).
- Autoimmune pancreatitis (AIP): Gluco-corticoid therapy in patients with AIP and sclerosing pancreatitis can induce clinical remission and significantly decrease serum concentrations of IgG4, immune complexes, and the IgG4 subclass of immune complexes. Starting dose of oral prednisolone is 0.6 to 1.0 mg/kg/day tapered over 3 mo. Recurrent AIP is treated with glucocorticoids and immunomodulators (azathioprine, mycophenolate, mercaptopurine) or rituximab.

CHRONIC Rx

- Surgical intervention may be necessary to eliminate biliary tract disease and improve flow of bile into the duodenum by eliminating obstruction of pancreatic duct.
- ERCP with endoscopic sphincterectomy and stone extraction is useful in selected patients.
- Transduodenal sphincteroplasty or pancreaticojejunostomy in selected patients. Surgery should also be considered in patients with intractable pain.
- Percutaneous or EUS-guided celiac plexus blockade using glucocorticoids is effective in providing short-term pain relief in nearly half of patients.

DISPOSITION

- Long-term survival is poor (50% of patients die within 10 yr from chronic pancreatitis or malignancy).
- Prognosis is best in patients with recurrent acute pancreatitis resulting from cholelithiasis, hyperparathyroidism, or stenosis of the sphincter of Oddi.

REFERRAL

Gastrointestinal referral for ERCP, surgical referral in selected patients (see "Chronic Rx")

AUTHOR: **Fred F. Ferri, MD**

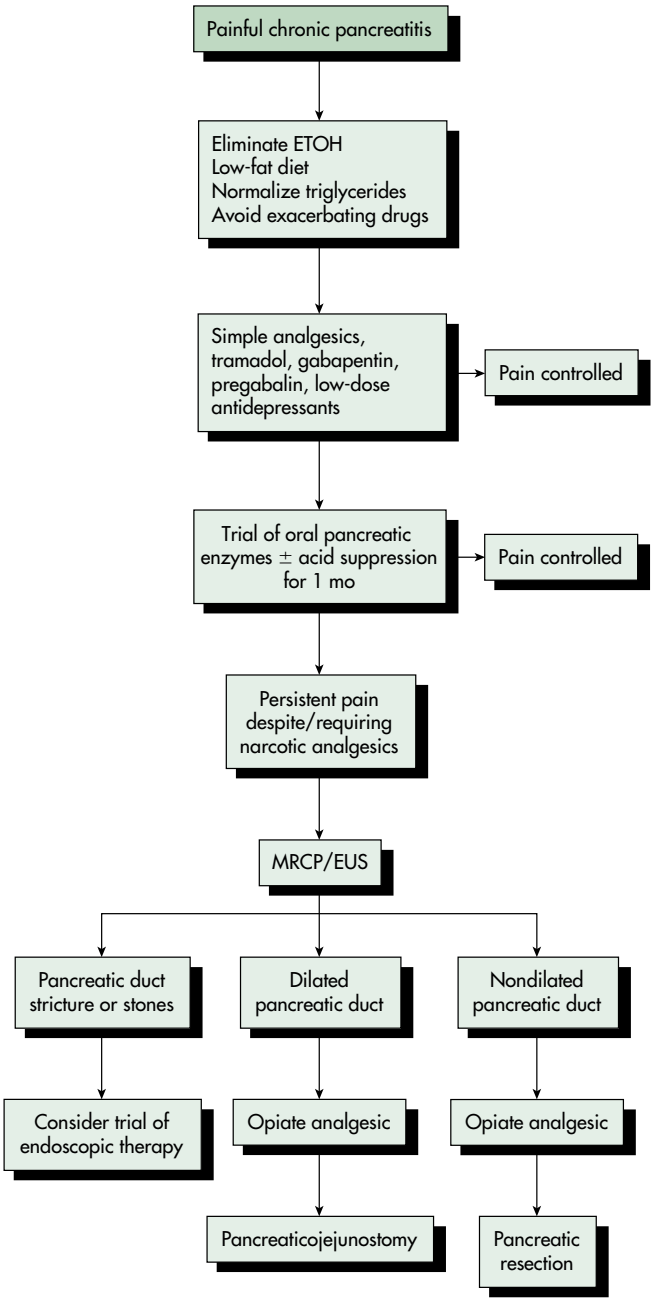

FIG. 5 Approach to the patient with painful chronic pancreatitis. *ETOH,* Alcohol; *EUS,* endoscopic ultrasound; *MRCP,* magnetic resonance cholangiopancreatography. (From Goldman L, Ausiello D [eds]: *Cecil textbook of medicine,* ed 24, Philadelphia, 2012, Saunders.)

TABLE 4 Enzyme Products for the Treatment of Chronic Pancreatitis

Product	Formulation	Lipase Content per Pill or Capsule (USP units)
Creon	Enteric-coated capsule	3000; 6000; 12,000; 24,000; 36,000
Zenpep	Enteric-coated capsule	3000; 5000; 10,000; 15,000; 20,000; 25,000
Pancreaze	Enteric-coated capsule	4200; 10,500; 16,800; 21,000
Ultresa	Enteric-coated capsule	13,800; 20,700; 23,000
Pertzye	Enteric-coated with bicarbonate	8000; 16,000
Viokase	Non–enteric-coated tablet*	10,440; 20,880

*Non–enteric-coated agents require cotreatment with an H2RA or PPI to avoid denaturation of the enzymes by gastric acid.
The total dose of lipase per meal should be titrated based on response but usually requires at least 60,000 and usually 90,000 USP units (30,000 international units) of lipase per meal and one half that amount with snacks. The dose should be split equally during the meal and immediately after the meal.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

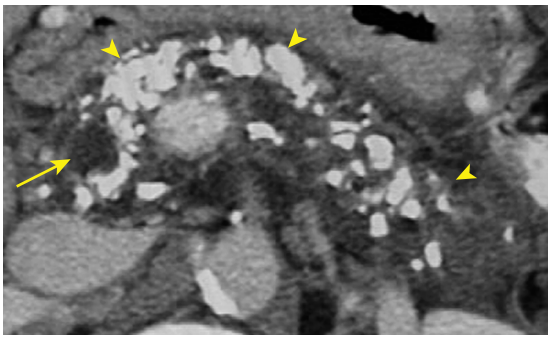

FIG. E1 Chronic pancreatitis: Calcifications. Numerous coarse calcifications are seen throughout the pancreas (*arrowheads*) in this patient with recurrent alcoholic pancreatitis. The common bile duct (*arrow*) is mildly dilated because of a benign stricture in the pancreatic head. (From Webb WR et al: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, WB Saunders.)

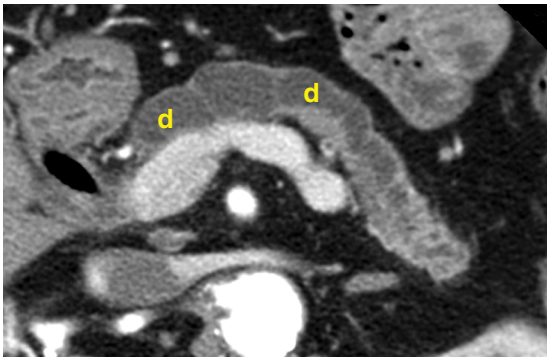

FIG. E2 Chronic pancreatitis: Dilated pancreatic duct. The pancreatic duct (*d*) shows marked beaded dilatation. The pancreatic parenchyma is severely atrophied. (From Webb WR et al: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, WB Saunders.)

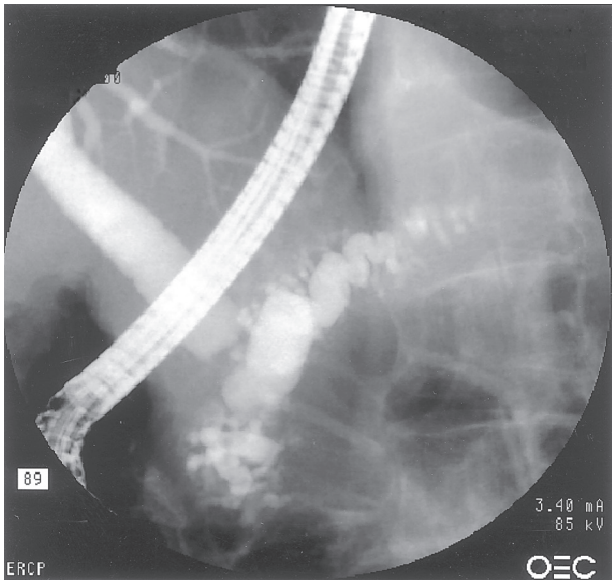

FIG. E3 Film from an endoscopic retrograde cholangiopancreatography (ERCP) showing a markedly dilated pancreatic duct with alternating strictures and dilatation. This "chain of lakes" appearance is diagnostic of chronic pancreatitis. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

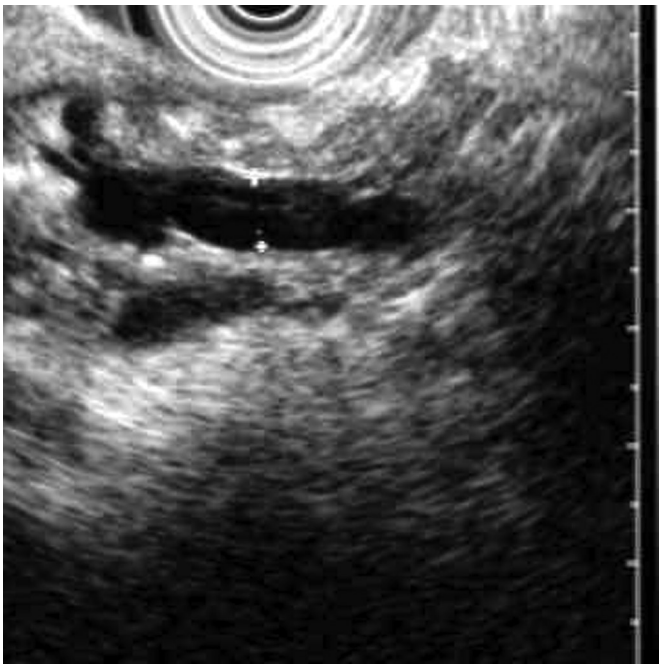

FIG. E4 Endoscopic ultrasound in a patient with chronic pancreatitis, demonstrating a dilated pancreatic duct (marks on margin of main duct). (From Goldman L, Schafer AI: *Goldman's Cecil medicine*, ed 24, Philadelphia, 2012, Saunders.)

TABLE E3 Diagnosis of Chronic Pancreatitis on Endoscopic Ultrasound (EUS)

Standard EUS Grading System		Rosemont Criteria for EUS Diagnosis	
Parenchymal abnormalities	Hyperechoic foci Hyperechoic strands Lobularity of contour Cysts	Major features	Hyperechoic foci with shadowing (major A) Main pancreatic duct calculi (major A) Lobularity with honeycombing (major B)
Ductal abnormalities	Main duct dilatation Main duct irregularity Hyperechoic ductal walls Visible side branches Calcification	Minor features	Lobularity without honeycombing Hyperechoic foci without shadowing Stranding Cysts Irregular main pancreatic duct contour Main pancreatic duct dilatation Hyperechoic duct margin Dilated side branches
In the standard EUS grading system, each finding counts equally, and the score is the total number of findings. In the Rosemont system, the diagnostic strata are as follows:			
Most consistent with chronic pancreatitis		One major A feature and ≥3 minor features *or* One major A feature and major B feature *or* Two major A features	
Suggestive of chronic pancreatitis		One major A feature and <3 minor features *or* One major B feature and ≥3 minor features *or* ≥5 minor features	
Indeterminate for chronic pancreatitis		Three to four minor features *or* One major B feature with <3 minor features	
Normal		≤2 minor features	

From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

Chronic Rhinosinusitis

BASIC INFORMATION

DEFINITION

Chronic rhinosinusitis (CRS) is an inflammatory condition that involves the paranasal passages and linings of the nasal passages that lasts 12 wk or longer despite medical therapy. It can be divided into three categories:

- CRS without nasal polyposis
- CRS with nasal polyposis
- Allergic fungal rhinosinusitis

SYNONYMS

Chronic sinusitis
CRS

ICD-10CM CODE
J32 Chronic sinusitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: CRS occurs in children and adults but is most frequently diagnosed in young and middle-aged adults
PREVALENCE: In the U.S. it varies from 1% to 5%
PREDOMINANT SEX AND AGE: Some studies suggest women are more affected. In adults, the mean age of diagnosis was 39 yr.
GENETICS: Patients with cystic fibrosis or primary ciliary dyskinesia are more likely to develop CRS.
RISK FACTORS:

- Environmental or behavioral risk factors include:
  1. Smoking
  2. Cocaine use
  3. Chemical and air pollutants: Ozone, sulfur dioxide, nitrogen dioxide
- Host-associated risk factors: Allergic rhinitis, atopy, asthma, aspirin-exacerbated respiratory disease
- Innate immunodeficiencies: Cystic fibrosis
- Humoral immunodeficiencies: Common variable immunodeficiency, IgA or IgG subclass deficiencies, types of vasculitis (e.g., Churg-Strauss syndrome), and sarcoidosis
- Allergic fungal sinusitis
- Gastroesophageal reflux disease
- Odontogenic: Infectious agents from maxillary posterior teeth may breech into maxillary sinus

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- CRS is diagnosed clinically with a physical examination and a detailed sinonasal history. There should be at least two out of the four cardinal symptoms for at least 12 consecutive wk:
  1. Nasal obstruction: 81% to 95% of patients
  2. Nasal drainage: 51% to 83% of patients
  3. Facial pain/pressure: 70% to 85% of patients
  4. Hyposmia/anosmia: 61% to 69% of patients
- Objective evidence on physical examination using anterior rhinoscopy and nasal endoscopy includes mucopurulent drainage, edema, polyps in the middle meatus
- Radiographic evidence includes, preferably, computed tomography (CT) of sinuses.
- Features of specific subtypes:
  1. CRS without nasal polyposis: Most common type (60% to 65% of cases) with cardinal clinical symptoms
  2. CRS with nasal polyposis: Characterized with the presence of bilateral nasal polyps in the middle meatus, which are translucent masses composed of gelatinous inflammatory material, as well as cardinal clinical symptoms
  3. Allergic fungal rhinosinusitis:
     a. Type 1 hypersensitivity confirmed by history, skin test, or serology
     b. Nasal polyposis
     c. Positive fungal stain
     d. Eosinophilic mucin showing fungal hyphae without tissue invasion
     e. CT of sinuses showing high-attenuation sinus contents with bony remodeling

ETIOLOGY

- Not fully understood but multifactorial involving host genetics and immunity, as well as environmental and infectious agents that produce chronic inflammation of the upper airways.
- Various cells, including fibroblasts, epithelial cells, endothelial cells, mast cells, eosinophils, antigen-presenting cells (dendritic cells), T cells, and B cells, have been shown to coordinate the immune inflammatory network underlying CRS, by the production of mediators such as cytokines, chemokines, eicosanoids, and antibodies.
- Microbiology: Organisms that may be involved in the pathogenesis of CRX include:
  1. *Staphylococcus aureus:* This is the most common bacterium and contributes to polyp formation. Methicillin-resistant *S. aureus* is isolated in 2% to 20% of patients with CRS.
  2. Coagulase-negative staphylococci: It is not always clear whether they are pathogens or colonizers.
  3. *Pseudomonas aeruginosa:* Occurs especially in patients with cystic fibrosis. Other gram-negative rods include *Klebsiella pneumoniae*, *Proteus mirabilis*, *Enterobacter* spp., and *E. Coli.*
  4. Anaerobic bacteria include: *Peptostreptococcus*, *Fusobacterium, Prevotella* spp., *Porphyromonas* spp.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Recurrent acute rhinosinusitis: ≥4 episodes a yr but symptom-free in between
- Allergic rhinitis, nonallergic rhinitis, vasomotor rhinitis, and eosinophilic nonallergic rhinitis
- Trigeminal neuralgia
- Tension headache

WORKUP

CRS is diagnosed clinically with a physical examination and focused sinonasal history, including the CRS-associated comorbidities and a pertinent family history

LABORATORY TESTS

Testing should be done to search for chronic conditions that may affect treatment:

- Asthma
- Cystic fibrosis
- Aspirin sensitivity
- Ciliary dyskinesia
- Immunodeficiencies: IgG deficiency, IgG subclass deficiency, IgA deficiency, selective IgA deficiency
- Assessment of patient allergies and immunologic status: IgG, IgA, IgM, and IgE levels; T-cell number; and function evaluation (delayed hypersensitivity skin test and flow cytometric quantification of T cells)
- Bacterial cultures via maxillary tap (maxillary sinus aspirate [MSA]) or endoscopically directed middle meatus culture (EDMM). MSA is the gold standard, with EDMM being considered equivalent

IMAGING STUDIES

- Plain films of sinuses are no longer recommended, with noncontrast-enhanced CT being the study of choice.
- Include all of the forehead and extend to maxillary teeth, also including the ears and nasal tip.
- Maintain a maximum slice of thickness of 1 mm, and obtain scans axially with no gantry tilt.

TREATMENT

The goal of treatment is to manage symptoms and to improve or maintain quality of life. Therapies are targeted to enhancing mucociliary clearance, improving sinus drainage/outflow, eliminating local infection and inflammation, and improving access for topical medications.

NONPHARMACOLOGIC THERAPY

Nasal saline irrigation: Low-pressure, high-volume (240 ml) isotonic or hypertonic saline irrigation can reduce symptoms in 50% of patients and is better than nasal saline spray. Often used in conjunction with intranasal corticosteroid spray.

ACUTE GENERAL Rx

- Topical intranasal corticosteroids: First-generation products include beclomethasone dipropionate (QNASL), flunisolide (Nasalide, Nasarel), budesonide (Rhinocort), and triamcinolone acetonide (Nasacort). Newer agents include fluticasone propionate (Flonase), fluticasone furoate (Veramyst), mometasone furoate (Asmanex), and ciclesonide (Omnaris). Most are used once a day.
- Oral corticosteroids: Oral corticosteroids, such as prednisone, can be used in patients

with severe disease and especially in patients with nasal polyps because they will help reduce the size of polyps. Prednisone will also minimize mucosal inflammation in allergic fungal rhinosinusitis. Dose: 20 mg twice daily for 5 days, then 20 mg daily for 5 days.
- Antibiotics: Often used in conjunction with prednisone. Can be used when evidence of infection present: Facial pain, air–fluid level on sinus CT, or purulent mucous in middle meatus. Use for up to 3 to 4 wk at most. Examples include amoxicillin/clavulanic acid or moxifloxacin.

SURGERY: Endoscopic surgery is appropriate if medical therapy fails. It can provide ventilation and drainage of the paranasal sinuses and enlarge the paranasal sinuses to create better access for topical medications. In general, it does not cure the condition and patients will need continued medical therapies.

CHRONIC Rx

Use of macrolide antibiotics for prolonged periods has been tried, but studies have not shown additional benefit.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Herbal medicines, homeopathy, acupuncture, reflexology, and yoga are used but have not been studied in clinical trials.

REFERRAL

- Otolaryngologist for long-term treatments and possible surgery

PEARLS & CONSIDERATIONS

- Surfactants such as baby shampoo can be added to saline irrigations and may prevent formation of bacterial biofilm on the sinus mucosa.
- Antihistamines such as cetirizine 20 mg used daily are of unproven benefit.

PREVENTION

- Smoking cessation is recommended because it reduces the risk for sinusitis.
- Nasal irrigation can be used as prevention for exacerbations of CRS.

Chronic Traumatic Encephalopathy (CTE)

BASIC INFORMATION

DEFINITION

Chronic traumatic encephalopathy (CTE) is a neurogenerative disorder often found in athletes, veterans, and those with repeated head injuries. It presents with cognitive, psychiatric, and sometimes motor symptoms.

SYNONYMS

CTE
Traumatic encephalopathy syndrome (clinical diagnosis)
Dementia pugilistica (older term)
Punch drunk syndrome (older term)

ICD-10CM CODE
G93.49 Other encephalopathy

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE & PREVALENCE: The incidence and prevalence of CTE are currently unknown. Among 202 deceased former football players, CTE was never pathologically diagnosed in 177 players (87%). Among participants with severe CTE pathology, 89% had behavior, mood symptoms, or both, 95% had cognitive symptoms, and 85% had signs of dementia.[1]
PREDOMINANT SEX AND AGE: CTE may present early (20s to 30s) or later (50s to 60s) in adulthood. The relationship with gender is unknown.
GENETICS: Currently there are no known genetic risk factors that predispose to the development of CTE.
RISK FACTORS: Repetitive head injuries leading to concussions are the strongest risk factor for the development of CTE. Athletes, veterans, and victims of repetitive head trauma are at highest risk.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Currently, it is thought that CTE presents in two forms. The first presents early in life (later 20s to 30s), with primarily psychiatric and behavioral manifestations. These may include depression, anxiety, paranoia, impulsivity, explosivity, and aggression. Cognitive problems are more common as the disease progresses. The second form presents later in life (60s), with mainly cognitive impairments and is likely to progress to dementia. Symptoms of this variant include impairment in episodic memory, attention, and executive function. Currently it is thought that CTE progresses in four stages with increasing severity along each stage. Symptoms progress from headaches, attention problems, and depression to explosivity, aggression, dementia, and suicidality as the disease progresses.

Physical findings are not always present in CTE but may include symptoms of parkinsonism and motor dysfunction, such as gait disturbance, tremors, ataxia, and dysarthria. These have been found to be particularly more common in boxers.

Of note, the symptoms of CTE may present similarly to the behavior subtype of frontotemporal dementia (FTD), but the characteristic disinhibition found in FTD is often missing. In addition, patients with traumatic brain injury may also have some symptoms of CTE, but these will present more acutely, whereas CTE develops after multiple yr of injuries.

ETIOLOGY

CTE is believed to occur due to repetitive head injuries. Definitive diagnosis is made only through autopsy, where neurofibrillary tangles and p-tau aggregates may be found around blood vessels and in deep cortical sulci, amygdala, hippocampus, brainstem, and cerebellum depending on the stage of the disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Alzheimer disease
- Frontotemporal dementia
- Post-concussion syndrome
- Bipolar disorder
- Major depressive disorder

WORKUP

CTE should be suspected in those with a history of repetitive head injuries and the symptoms previously listed. The history and progression of symptoms is of most benefit in the diagnostic process. Neuropsychological testing may be helpful in delineating specific cognitive deficits.

LABORATORY TESTS

Tests including complete blood count, comprehensive metabolic panel, thyroid function tests, HIV, syphilis

IMAGING STUDIES

- MRI may aid in ruling out other causes of dementia.
- The usefulness of advanced imaging such as PET, SPECT, and DTI in CTE is still under investigation.

TREATMENT

NONPHARMACOLOGIC THERAPY

Cognitive behavioral therapy is helpful for depression and anxiety symptoms.

ACUTE GENERAL Rx

- **SSRIs,** especially sertraline and citalopram, may be effective in treating depression symptoms. Close monitoring for suicidality is recommended in all patients with CTE.
- **Methylphenidate** has been shown to help in alleviating agitation, irritability, and aggressive symptoms.
- **Pain management** to improve quality of life.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None

DISPOSITION

CTE is chronic and progressive. Emphasis should be placed on improving quality of life through pain management, therapy, and symptom management.

REFERRAL

Patients may benefit from referral to neurology, psychiatry, and psychology.

PEARLS & CONSIDERATIONS

COMMENTS

CTE is a slowly developing illness. Although it should be considered in patients with repetitive head injuries, it is important to conduct a thorough work-up to rule out psychiatric illnesses and other forms of dementia that may present with similar symptoms.

PREVENTION

For athletes, wearing proper protective equipment as well as using techniques to avoid direct head impacts when playing sports is important. Furthermore, if a concussion is suspected, the player should not be allowed to resume play without further evaluation.

BASIC INFORMATION

DEFINITION

Chronic urticaria (CU) is the occurrence of hives (edematous, pruritic pink wheals of variable size and shape) that have been present continuously or intermittently for at least 6 wk. Some patients may also experience angioedema (deep, often painful, swelling). CU can be associated with autoimmune conditions but is often idiopathic. A classification of chronic urticaria subtypes and diseases related to urticaria is summarized in Table E1. When no underlying cause is found, CU has been referred to as chronic idiopathic urticaria (CIU).

SYNONYMS

Chronic hives
CU
CIU
Chronic idiopathic urticaria
Chronic spontaneous urticaria
CSU

ICD-10CM
L50.8 Other urticaria: Chronic urticaria

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1.4% per yr.
PREVALENCE: Lifetime prevalence is 1.8%. The period prevalence in the last 12 mo is 0.6% to 0.8%. CU occurs in 0.1% to 0.3% of children.
PREDOMINANT AGE AND SEX: There is a 2:1 female to male predominance. The mean age is 40 yr.
RISK FACTORS: None.
GENETICS: Patients with demonstrable histamine-releasing autoantibodies have a very strong association with HLA-DR4 and the associated allele HLA-DQ8.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- CU lesions are edematous, pink or red wheals of variable size and shape with surrounding erythema (Fig. E1) and are usually pruritic. Individual urticarial lesions usually resolve within 24 hr, but new lesions may be developing simultaneously.
- Angioedema typically appears as brawny nonpitting edema, often without well-defined margins, and erythema, commonly affecting the lips, tongue, eyelids, and genitalia. This is often described as painful rather than pruritic.

ETIOLOGY

- CU results from cutaneous mast cells releasing histamine. It is often triggered by immunoglobulin E (IgE), components of the complement cascade, endogenous peptides, endorphins, and enkephalins.
- More than 30% of patients have autoimmune manifestations, including specific IgG antibodies against the FcεRIα subunit of the high-affinity IgE receptor or IgG antibodies against IgE itself, thyroid autoimmunity, or positive autologous serum skin test (ASST).
- Activation of the coagulation cascade, including increased levels of prothrombin fragment F112 and D-dimer, has been noted in patients with CU and may be a marker for CU severity.
- Chronic infections such as hepatitis B and C, Epstein-Barr virus (EBV), herpes simplex virus, and helminthic parasitic infections have been implicated. There is also an association with autoimmune diseases such as type 1 DM and hypothyroidism (Fig. E2).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Urticarial vasculitis
- Erythema multiforme
- Drug eruptions
- Still disease
- Insect bites

WORKUP

- Complete history and physical exam: Questioning about new drugs, travel, infection, health status, and a complete review of systems (including fever, arthralgias, abdominal pain, bone pain, weight loss, and cold/heat sensitivity) is important. Determining if an individual lesion resolves within 24 hours, whether lesions are tender or itchy, and whether lesions leave a purpuric mark is important (to screen for urticarial vasculitis).
- Fig. E3 describes an algorithm for the diagnosis and management of chronic urticaria.

LABORATORY TESTS

- In a systemic review analyzing 29 studies (6462 patients), a causative internal disease was detected in 1.6% of patients with CU, with no association between the number of tests ordered and the detection rate.
- Aside from a complete history and physical examination, a trial of antihistamine therapy without further diagnostic testing is recommended.
- In those who fail antihistamine therapy, there is consensus for a limited laboratory workup:
  1. CBC with differential, complete metabolic panel (creatinine, liver function tests), ESR, TSH

TABLE E1 Classification of Chronic Urticaria Subtypes and Diseases Related to Urticaria

Chronic urticaria subtypes	Chronic spontaneous urticaria	Spontaneous appearance of wheals, angioedema, or both ≥6 wks due to known or unknown causes
	Inducible urticaria	1. Symptomatic dermatographism* 2. Cold urticaria† 3. Delayed pressure urticaria‡ 4. Solar urticaria 5. Heat urticaria§ 6. Vibratory angioedema 7. Cholinergic urticaria 8. Aquagenic urticaria 9. Contact urticaria
Diseases related to urticaria		1. Serum sickness–like reaction; urticarial vasculitis 2. Bradykinin-mediated angioedema (e.g., hereditary angioedema) 3. Mast cell disorders (e.g., urticaria pigmentosa) 4. Exercise-induced anaphylaxis
Syndromes that present with wheals and/or angioedema		• Cryopyrin-associated periodic syndromes (CAPS) 1. Familial cold autoinflammatory syndrome (FCAS) 2. Muckle–Wells syndrome (MWS) 3. Neonatal onset multisystem inflammatory disease (NOMID) • Schnitzler syndrome • Gleich syndrome

*Also called *urticaria factitia* dermatographic urticaria.
†Also called *cold contact urticaria.*
‡Also called *pressure urticaria.*
§Also called *heat contact urticaria.*
From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.

FIG. E1 Urticarial lesions in a patient with urticarial vasculitis. These lesions may take several days to resolve. (From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

FIG. E2 Urticaria. Chronic urticaria in this teenager in association with autoimmune diseases type 1 diabetes and hypothyroidism. Treatment with antihistamines was not successful, and the patient required systemic corticosteroids and methotrexate for control. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

2. Typically also check G6PD, hepatitis B and C, HIV, and age-appropriate malignancy screening

- A skin biopsy may be performed in cases of suspected urticarial vasculitis or urticaria with atypical historical or physical findings.
- NOTE: Testing for autoantibodies to the high-affinity IgE receptor, autoantibodies to IgE, basophil histamine response assay (BHRA), or the ASST is not routinely recommended. However, in the setting of omalizumab therapy, a quick response to the medication is associated with IgG autoantibodies to IgE and a high IgE level in the serum, whereas a delayed response to the medication is associated with the presence of IgG autoantibodies to the high-affinity IgE receptor or positive BHRA and ASST testing.
- C4 testing is recommended in patients with isolated angioedema (without urticaria) to rule out C1 inhibitor deficiency.

IMAGING STUDIES

None

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Elimination of any suspected medications, herbal products, etc.

ACUTE GENERAL Rx

Oral corticosteroids are not recommended as long-term treatment because of their detrimental effects over prolonged periods. However, they may be necessary for 3 to 7 days to abort severe, acute flares.

CHRONIC Rx

FIRST-LINE TREATMENT:

- Second-generation nonsedating H1-antagonist antihistamines:
  1. Loratadine 10 mg, fexofenadine 180 mg, cetirizine 10 mg, levocetirizine 2.5 mg, or desloratadine 5 mg—started as twice daily dosing.
  2. These are the mainstay of treatment, with 50% to 95% of patients achieving satisfactory disease control with one or a combination of antihistamines only. The typical starting dose is twice daily. If no improvement after 2 wk, there is current data supporting dose-escalation to fourfold on-label dosing. Studies have shown routine (rather than episodic) use is important for efficacy.
- Sedating H1-antagonist antihistamines (diphenhydramine, hydroxyzine) are no longer recommended as first-line treatment given their potential for sedation and anticholinergic effects, as well as the availability of second-generation agents. However, these can be used as adjuncts at bedtime.

SECOND-LINE TREATMENT: For those who do not respond to monotherapy H1-antagonist, adding an additional agent with the goal of combination antihistamine therapy may be necessary:

- Addition of a second nonsedating H1 antihistamine.
- Addition of H2 blockade (ranitidine, famotidine, or cimetidine).
- Addition of doxepin 25 to 50 mg at night or twice daily (which is a potent H1/H2 blocker) may be necessary. Of note, doxepin can prolong PR interval and worsen conduction defects; an ECG before initiation may be warranted.

THIRD-LINE TREATMENT: Choice of agent depending on histologic infiltrate (e.g., neutrophilic), patient's comorbidities, and preferences. If failed the above treatments, patients are typically considered refractory CIU. International consensus groups have determined omalizumab, a monoclonal antibody against IgE, to be the most appropriate next therapeutic option.

- Omalizumab 300 mg subcutaneous injection every 4 wk. This is approved in both the U.S. and EU for the treatment of antihistamine-resistant CIU. No specific labs recommended to predict favorable response at this time. Approximately 30% to 45% are hive free by 3 mo, with response noted as early as 1 wk. Treatment failure can be determined at 16 wk. With combination maximum dose antihistamines, efficacy increased to 80% of patients being hive free. Hence antihistamines should be continued and slowly tapered. Although risk of anaphylaxis is no higher than other biologics, it is given in office with patients being given an epi-pen.
- Monthly SC injections of ligelizumab, a new anti-IgG monoclonal antibody, have shown significant efficacy in chronic urticaria.

FOURTH-LINE TREATMENT:

- Addition of leukotriene-receptor antagonist (e.g., montelukast 10 mg/day).
- Dapsone 25 to 500 mg/day (typically 100 mg/day starting dose). Must check for G6PD and monitor labs. Limited use in patients with anemia. Side effects include peripheral neuropathy, methemoglobinemia, agranulocytosis, and systemic drug hypersensitivity. Improvement is generally noted within days to wks.
- Hydroxychloroquine 200 mg twice daily (can start with dapsone or sulfasalazine because of slow onset on the order of 3 mo). Must monitor for retinal toxicity.
- Sulfasalazine 500 mg twice daily (then uptitrate to 1 g twice daily). Good option if patient is anemic and cannot tolerate dapsone.

IMMUNOSUPPRESSIVE AGENTS

- Mycophenolate mofetil 500 to 1500 mg twice daily
- Cyclosporine (3 to 5 mg/kg per day for 3 to 6 mo). Limited by nephrotoxic potential. Should not be used longer than a yr.

Phototherapy

- In a recent study, narrow band UVB (NB-UVB) was effective and safe in steroid-dependent patients with chronic refractory urticaria.

COMPLEMENTARY & ALTERNATIVE MEDICINE

A combination of ear acupuncture and conventional filiform needle acupuncture has been reported.

REFERRAL

Dermatology and/or allergy and immunology referral for patients who fail antihistamine therapy or in whom there is a concern for urticarial vasculitis.

PEARLS & CONSIDERATIONS

COMMENTS

- In atypical cases, given a patient's history or appearance, a skin biopsy for histologic evaluation can be helpful.
- Antihistamine blockade response can often be determined by the presence of dermatographism on exam (wheal produced by scratching).

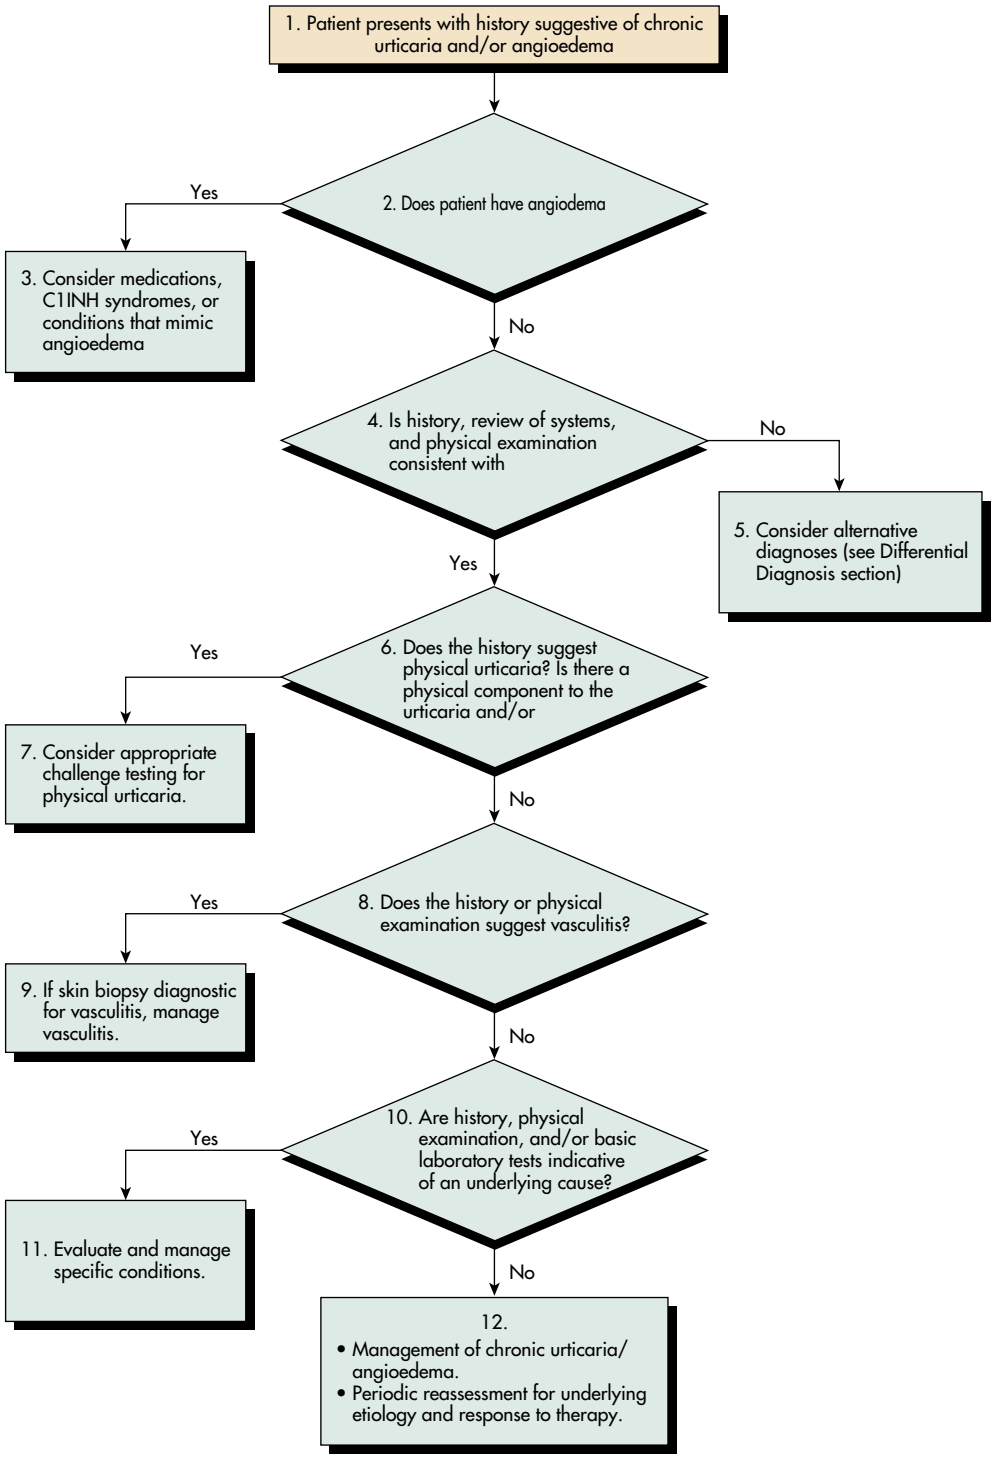

FIG. E3 Algorithm for the diagnosis and management of chronic urticaria. *C1INH,* C1-esterase inhibitor. (From Bernstein JA et al: The diagnosis and management of acute and chronic urticaria: 2014 update, *J Allergy Clin Immunol* 133:1270-1277, 2014.)

PREVENTION

- Measures that increase vasodilation such as alcoholic drinks, excessive ambient temperature, heavy clothing, hot baths or showers, and spicy food should be avoided.
- Up to 15% of CU patients experience an exacerbation of their disease after taking aspirin or other cyclooxygenase-1 (COX-1) inhibitors. Patients should be cognizant of such reactions to these medications.

PATIENT & FAMILY EDUCATION

- A cause is typically not identified.
- Patients should be aware that the course of disease is unpredictable and may last months to years. However, reassurance should be given that 50% of patients experience remission within 1 yr. In one study, the duration of disease ranged from 1 to 5 yr in 8.7% and more than 5 yr in 11.3% of patients.
- CIU is different from acute urticaria in etiology, and it is typically not a dietary cause. That said, some providers feel that pseudoallergens in foods can play a role in exacerbations but do not recommend a pseudoallergen-free diet.

BASIC INFORMATION

DEFINITION

Cirrhosis is defined histologically as the presence of irreversible fibrosis in the liver. It can be classified as micronodular, macronodular, or mixed; however, each form may be seen in the same patient at different stages of the disease, and this classification system has little utility in determining the underlying etiology of cirrhosis. Cirrhosis manifests clinically with portal hypertension, ascites and peripheral edema, hepatic encephalopathy, and variceal bleeding.

ICD-10CM CODES

K70.30	Alcoholic cirrhosis of liver without ascites
K70.31	Alcoholic cirrhosis of liver with ascites
K71.7	Toxic liver disease with fibrosis and cirrhosis of liver
K74.3	Primary biliary cirrhosis
K74.4	Secondary biliary cirrhosis
K74.5	Biliary cirrhosis, unspecified
K74.60	Unspecified cirrhosis of liver
K74.69	Other cirrhosis of liver
P78.81	Congenital cirrhosis (of liver)

EPIDEMIOLOGY & DEMOGRAPHICS

- Cirrhosis was the fourteenth-leading cause of death in the U.S. in 2015 and the thirteenth-leading cause of death globally. In the U.S., cirrhosis-related deaths increased 3.4% annually between 2009 and 2016.
- Alcohol abuse, hepatitis C, and nonalcoholic steatohepatitis are the major causes of cirrhosis in the U.S.
- Economic burden of cirrhosis in the U.S. exceeds $2 billion in direct costs and over $10 billion in indirect costs.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

GENERAL: Fever (spontaneous bacterial peritonitis)
SKIN: Jaundice, palmar erythema, spider angiomata, ecchymosis (thrombocytopenia or coagulation factor deficiency), increased pigmentation (hemochromatosis), xanthomas (primary biliary cirrhosis), and diffuse pruritus. Cutaneous lesions often accompany cirrhosis and can be found in >40% of people with chronic alcoholism
EYES: Kayser-Fleischer rings (corneal copper deposition seen in Wilson disease; best diagnosed with slit lamp examination), scleral icterus
BREATH: Fetor hepaticus (breath has a sweet musty odor found in cirrhosis with hepatic failure)
CHEST: Possible gynecomastia in men
ABDOMEN: Tender or nontender hepatomegaly (congestive hepatomegaly), small, nodular liver (cirrhosis), palpable, nontender gallbladder (neoplastic extrahepatic biliary obstruction), palpable spleen (portal hypertension), dilated superficial periumbilical vein (caput medusae), venous hum auscultated over periumbilical veins (portal hypertension), ascites (portal hypertension, hypoalbuminemia), diffuse abdominal tenderness (spontaneous bacterial peritonitis)
RECTAL EXAMINATION: Hemorrhoids (portal hypertension), guaiac-positive stools (alcoholic gastritis, bleeding esophageal varices, peptic ulcer disease, bleeding hemorrhoids, portal gastropathy)
GENITALIA: Testicular atrophy in males (chronic liver disease, hemochromatosis)
EXTREMITIES: Pedal edema (hypoalbuminemia, anasarca), arthropathy (hemochromatosis), Dupuytren contractures
NEUROLOGIC: Asterixis (hepatic encephalopathy), choreoathetosis, dysarthria (Wilson disease)

ETIOLOGY

- Chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infection
- Alcoholism
- Nonalcoholic steatohepatitis
- Primary biliary cholangitis
- Secondary biliary cirrhosis, obstruction of the common bile duct (stone, stricture, pancreatitis, neoplasm, sclerosing cholangitis)
- Autoimmune hepatitis
- Drugs with chronic hepatitis (e.g., acetaminophen, isoniazid, methotrexate, methyldopa)
- Chronic hepatic congestion (e.g., CHF, constrictive pericarditis, tricuspid insufficiency, thrombosis of the hepatic vein, obstruction of the vena cava)
- Hemochromatosis
- Wilson disease
- Alpha-1-antitrypsin deficiency
- Infiltrative diseases (amyloidosis, glycogen storage diseases, nonhepatocellular malignancies)
- Nutritional: Jejunoileal bypass
- Others: Parasitic infections (schistosomiasis), idiopathic portal hypertension, congenital hepatic fibrosis, systemic mastocytosis

DIAGNOSIS

WORKUP

In addition to an assessment of liver function, the evaluation of patients with cirrhosis should also include an assessment of renal and circulatory function. Diagnostic workup is aimed primarily at identifying the most likely cause of cirrhosis. The history is extremely important:

- Alcohol abuse: Alcoholic liver disease
- History of hepatitis B or hepatitis C
- Obesity, type 2 diabetes mellitus, hyperlipidemia (nonalcoholic steatohepatitis)
- History of IBD (primary sclerosing cholangitis)
- History of pruritus, hyperlipoproteinemia, and xanthomas in a middle-aged or elderly woman (primary biliary cholangitis)
- Impotence, diabetes mellitus, hyperpigmentation, arthritis (hemochromatosis)
- Neurologic disturbances (Wilson disease, hepatolenticular degeneration)
- Family history of "liver disease" (hemochromatosis [positive family history in 25% of patients], alpha-1-antitrypsin deficiency)
- History of recurrent episodes of right upper quadrant pain (biliary tract disease)
- History of blood transfusions, IV drug abuse (hepatitis C)
- History of repetitive hepatotoxic drug exposure
- Coexistence of other diseases with immune or autoimmune features (immune thrombocytopenic purpura, myasthenia gravis, thyroiditis, autoimmune hepatitis)
- Biopsy is the gold standard to diagnosis cirrhosis and is helpful when multiple etiologies are possible that might change management (autoimmune hepatitis, small duct primary sclerosing cholangitis, antimitochondrial antibody-negative primary biliary cholangitis, and infiltrative diseases such as lymphoma, amyloidosis, and granulomatous hepatitis). However, it is generally unnecessary if the clinical picture is highly suggestive of cirrhosis and management would not change. Biopsy can be useful in actively drinking patients with cirrhosis to distinguish between decompensated cirrhosis and cirrhosis with alcoholic hepatitis

LABORATORY TESTS

- Decreased hemoglobin and hematocrit, elevated mean corpuscular volume (Fig. E1). Increased blood urea nitrogen (BUN) and creatinine (the BUN may also be "normal" or low if the patient has severely diminished liver function).
- Decreased sodium (dilutional hyponatremia), and decreased potassium (as a result of secondary aldosteronism or urinary losses). Evaluation of renal function should also include measurement of urinary sodium and urinary protein from 24-hr urine collection.
- Decreased glucose in a patient with liver disease indicates severe liver damage.
- Other laboratory abnormalities:
  1. Alcoholic hepatitis and cirrhosis: Possible mild elevation of alanine aminotransferase (ALT) and aspartate aminotransferase (AST), usually <500 IU; AST >ALT (ratio >2:3).
  2. Extrahepatic obstruction: Possible moderate elevations of ALT and AST to levels <500 IU.
  3. Viral, toxic, or ischemic hepatitis: Extreme elevations (>500 IU) of ALT and AST.
  4. Transaminases may be normal despite significant liver disease in patients with jejunoileal bypass operations or hemochromatosis or after methotrexate administration.
  5. Alkaline phosphatase elevation can occur with extrahepatic obstruction, primary biliary cholangitis, and primary sclerosing cholangitis.
  6. Serum lactate dehydrogenase is significantly elevated in metastatic disease of the liver; lesser elevations are seen with

hepatitis, cirrhosis, extrahepatic obstruction, and congestive hepatomegaly.
7. Serum gamma-glutamyl transpeptidase is elevated in alcoholic liver disease and may also be elevated with cholestatic disease (primary biliary cholangitis, primary sclerosing cholangitis).
8. Serum bilirubin may be elevated; urinary bilirubin can be present in hepatitis, hepatocellular jaundice, and biliary obstruction.
9. Serum albumin: Significant liver disease results in hypoalbuminemia. Malnutrition occurs in 20% to 60% of patients with cirrhosis.

- Prothrombin time/INR: Elevation in patients with liver disease indicates severe liver damage and poor prognosis. Table 1 summarizes hemostatic balance in liver disease.

1. Presence of hepatitis B surface antigen implies acute or chronic hepatitis B.
2. Presence of antimitochondrial antibody suggests primary biliary cholangitis, chronic hepatitis.
3. Elevated serum copper, decreased serum ceruloplasmin, and elevated 24-hr urine may be diagnostic of Wilson disease.
4. Protein immunoelectrophoresis may reveal decreased α-1 globulins (alpha-1-antitrypsin deficiency), increased IgA (alcoholic cirrhosis), increased IgM (primary biliary cirrhosis), increased IgG (chronic hepatitis, cryptogenic cirrhosis).
5. An elevated serum ferritin and increased iron saturation are suggestive of hemochromatosis.
6. An elevated blood ammonia suggests hepatocellular dysfunction; serial values, however, are generally not useful in monitoring patients with hepatic encephalopathy because there is poor correlation between blood ammonia level and degree of hepatic encephalopathy.
7. Serum cholesterol is elevated in cholestatic disorders.
8. Antinuclear antibodies (ANA) may be found in autoimmune hepatitis.
9. Alpha fetoprotein: Levels >1000 pg/ml are highly suggestive of hepatocellular carcinoma.
10. Hepatitis C viral testing identifies patients with chronic hepatitis C infection.
11. Elevated level of serum globulin (especially gamma-globulins) and positive ANA test may occur with autoimmune hepatitis.
12. End-stage liver disease is characterized by decreased levels of most procoagulant factors with the notable exceptions of factor VIII and von Willebrand factor, which are elevated. Table 2 summarizes hemostatic indices in liver disease.

TABLE 1 Hemostatic Balance in Liver Disease

	Promotes Thrombosis	Promotes Bleeding
Primary hemostasis	• Increased vWF • Decreased ADAMTS13	• Thrombocytopenia • Platelet dysfunction
Secondary hemostasis	• Increased factor VIII • Decreased protein C, protein S, antithrombin	• Factor deficiencies: II, V, VII, IX, XI • Vitamin K deficiency • Hypofibrinogenemia • Dysfibrinogenemia
Fibrinolysis	• Reduced plasminogen • Increased PAI-1	• Reduced α2-antiplasmin, TAFI, factor VIII • Increased t-PA

ADAMST13, A disintegrin and metalloproteinase with thrombospondin; *PAI-1,* plasminogen activator inhibitor-1; *TAFI,* thrombin activatable fibrinolysis inhibitor; *t-PA,* tissue plasminogen activator; *vWF,* von Willebrand factor.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

IMAGING STUDIES

- Ultrasonography is the procedure of choice. It can identify the size and shape of the liver (generally small and nodular in advanced cirrhosis) and can detect gallstones and dilation of bile ducts. The use of sonography on a periodic basis to screen for hepatocellular carcinoma in patients with cirrhosis should be considered.
- CT scan (Figs. 2 and 3) is useful for detecting mass lesions in liver and pancreas, assessing hepatic fat content, identifying idiopathic hemochromatosis, diagnosing Budd-Chiari syndrome early, assessing dilation of intrahepatic bile ducts, and detecting varices and splenomegaly. However, ultrasound is generally the preferred imaging modality of choice.
- MRI can be used to identify hemangiomas, hepatocellular carcinoma.
- Vibration-controlled transient elastography and magnetic resonance elastography are useful to assess advanced fibrosis. These noninvasive tests are less expensive and safer than biopsy and can be repeated over time to monitor disease progression.
- Technetium-99m sulfur colloid scanning is rarely used but can be useful for diagnosing cirrhosis (there is a shift of colloid uptake to the spleen and bone marrow), identifying hepatic adenomas (cold defect is noted), and diagnosing Budd-Chiari syndrome (there is increased uptake by the caudate lobe).
- Endoscopic retrograde cholangiopancreatography can be used for diagnosing periampullary carcinoma and common duct stones; it is also useful in diagnosing primary sclerosing cholangitis.
- Percutaneous transhepatic cholangiography is useful when evaluating patients with cholestatic jaundice and dilated intrahepatic ducts by ultrasonography; presence of intrahepatic strictures and focal dilation is suggestive of primary sclerosing cholangitis.

TABLE 2 Hemostatic Indices in Liver Disease

Laboratory Changes	PT	PTT	TCT	Fib	Clauss	Plt	Platelet Aggregation	FVII	DD	ELT

DIC	N/↑	N/↑	N/↑	↓	↓	↓	N	N/↓	↑	↓

Clauss, Clauss fibrinogen; *DD,* D-dimer; *DIC,* disseminated intravascular coagulation; *ELT,* euglobulin lysis time (measure of fibrinolysis); *Fib,* fibrinogen; *FVII,* factor VII functional assay; *N,* normal; *Plt,* platelet; *PT,* prothrombin time; *PTT,* partial thromboplastin time; *TCT,* thrombin clotting time.
[a]Differentiating between vitamin K deficiency and liver disease can be challenging with conventional laboratory tests. If available, performing a factor II assay with and without Echis venom (factor II biologic and factor II Echis) may be useful. Ecarin is derived from *Echis carinatus* snake venom and can activate prothrombin irrespective of γ-carboxylation. Factor II activity (biologic) is reduced in both vitamin K deficiency and liver disease. In contrast, the factor II Echis is reduced in liver disease but is normal in vitamin K deficiency.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid any hepatotoxins (e.g., ethanol, acetaminophen), improve nutritional status, vaccinate against hepatitis A and B if not already immune.
- Transjugular intrahepatic portosystemic shunt (TIPS) in patients with recurrent variceal hemorrhage despite optical medical therapy (Fig. 4). Early use of TIPS is associated with significant reductions in treatment failure and in mortality in patients with cirrhosis who are hospitalized for acute variceal bleeding and are at high risk for treatment failure.
- Correction of malnutrition: Daily protein intake of 1.0 to 1.5 g per kg of body weight.

ACUTE GENERAL Rx

- Nonselective beta blockers (nadolol, propranolol) in patients with cirrhosis and variceal hemorrhage, and some without hemorrhage but with high-risk bleeding features. Use with caution in patients with severe alcoholic hepatitis and decompensated cirrhosis with refractory ascites. Beta-blockers should be temporarily discontinued in patients with spontaneous bacterial peritonitis due to increased mortality and hepatorenal syndrome incidence.
- Pruritus due to liver disease may be treated with cholestyramine 4 g/day initially. Dose can be increased to 24 g/day as needed.
- Pain management: Avoid opiates (may precipitate or aggravate hepatic encephalopathy) and NSAIDs (increased risk of gastrointestinal bleeding and renal failure). Low-dose tramadol and lidocaine patches are generally well tolerated.
- Sedatives: Benzodiazepines (lorazepam or oxazepam) may be used for alcohol withdrawal but should be avoided in patients with hepatic encephalopathy. Avoid benzodiazepines with liver metabolites (diazepam, chlordiazepoxide).
- Statins: Can be safely started and continued in patients with hyperlipidemia and/or nonalcoholic fatty liver disease.
- Proton pump inhibitors: Not routinely indicated; their use in patients with cirrhosis is associated with excess risk for spontaneous bacterial peritonitis and hepatic encephalopathy; avoid indiscriminate use of PPIs in patients with cirrhosis.
- Antibiotics: Trimethoprim-sulfamethoxazole or ciprofloxacin/norfloxacin for spontaneous bacterial peritonitis prophylaxis in patients with a history of SBP, an ascites protein concentration less than 1 g/dl, or history of variceal hemorrhage.
- Liver transplantation may be indicated in otherwise healthy patients (ages <65 yr) with severe cirrhosis and lack of contraindications. Contraindications to liver transplantation are AIDS, most metastatic malignancies, active substance abuse, uncontrolled sepsis, and uncontrolled cardiac or pulmonary disease.
- Treatment of complications of portal hypertension (ascites, esophagogastric varices, hepatic encephalopathy, spontaneous bacterial peritonitis, and hepatorenal syndrome; refer to these individual topics in Section I).
- Box 1 summarizes the management of coagulopathy in liver disease.

TREATMENT BASED ON SPECIFIC CAUSE OF CIRRHOSIS

- Remove excess body iron with phlebotomy and deferoxamine in patients with hemochromatosis.
- Remove copper deposits with D-penicillamine in patients with Wilson disease.
- Long-term ursodiol therapy will slow the progression of primary biliary cholangitis. It is, however, ineffective in primary sclerosing cholangitis.
- Glucocorticoids (prednisone 20 to 30 mg/day initially or combination therapy or prednisone and azathioprine) are useful in autoimmune hepatitis.
- Antivirals in chronic hepatitis C.

PROGNOSIS

- Prognosis varies with the etiology of the patient's cirrhosis and whether there is ongoing hepatic injury. Patients with compensated cirrhosis (no associated complications or esophageal varices without bleeding) have a good prognosis with median survival of 12 yr.
- In patients with decompensated cirrhosis, the Model for End-stage Liver Disease with sodium (MELDNa) scoring is useful to predict 3-mo mortality and so is the main method of prioritizing patients awaiting liver transplantation. It also has prognostic value following TIPS placement for patients with cirrhosis undergoing nontransplant surgeries. Mortality rate exceeds 80% in patients with hepatorenal syndrome.
- Regression of cirrhosis has been demonstrated after antiviral therapy in some patients with chronic hepatitis C. Regression is associated with decreased disease-related morbidity and improved survival.
- Cirrhosis is associated with an increased risk for hepatocellular carcinoma. However, the risk is low (1% 5-yr cumulative risk in alcoholic cirrhosis).

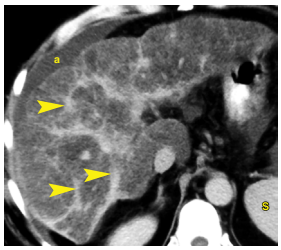

FIG. 2 Advanced cirrhosis with fatty infiltration. Delayed portal venous–phase computed tomography reveals that the liver is misshapen and nodular in contour. Parenchymal density that is significantly lower than that of the spleen *(S)* is indicative of fatty infiltration and continuing liver injury. Prominent scars and bands of fibrosis *(arrowheads)* are seen throughout the liver. Ascites *(a)* is present. (From Webb WR et al: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, Saunders.)

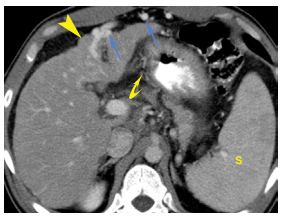

FIG. 3 Cirrhosis with portal hypertension. Postcontrast computed tomography reveals a liver that is nodular in contour *(arrowhead)* with patent enlarged paraumbilical veins (*blue arrows*) and splenomegaly *(S)*, findings indicative of portal hypertension. Mildly enlarged portosystemic collateral vessels (*curved arrow*) are also evident in the gastrohepatic ligament. (From Webb WR et al: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, Saunders.)

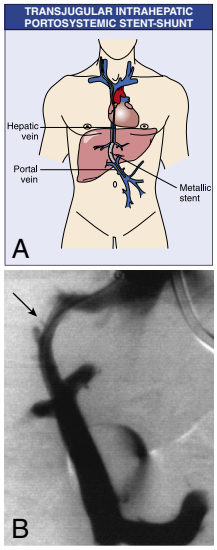

FIG. 4 Transjugular intrahepatic portosystemic stent shunt. A, An intrahepatic track has been created between the right hepatic vein and the right portal vein. **B,** The track is dilated *(arrow)* and stented, creating a shunt as demonstrated on shuntogram. (Courtesy Dr. W. K. Tso, Queen Mary Hospital, Hong Kong.)

PEARLS & CONSIDERATIONS

COMMENTS

- Thrombocytopenia and advanced Child-Pugh classes (Table 3) are associated with the presence of varices. These factors are useful to identify cirrhotic patients who benefit most from referral for endoscopic screening for varices.
- A combination of endoscopic and drug therapy reduces overall and variceal rebleeding in cirrhosis more than either therapy alone.

BOX 1 Management of coagulopathy in liver disease

- Actively bleeding patients should be adequately resuscitated. Admission to the intensive care setting may be appropriate.
- Basic coagulation tests should be ordered to identify the cause of bleeding; these include CBC, PT (INR), PTT, thrombin clotting time, fibrinogen, D-Dimer, FDP, and mixing studies. The need for more specialized tests will be dictated by the clinical situation and response to therapy.
- It is important to identify any localized source of bleeding (e.g., varices) amenable to procedural intervention to achieve hemostasis.
- A trial of 5 to 10 mg of vitamin K is reasonable in asymptomatic patients with prolonged PT and PTT but should be used with other therapies in actively bleeding patients.
- In patients with thrombocytopenia platelet transfusions can be used, targeting platelet counts greater than 50 × 109 /L.
- In patients who can tolerate volume, FP 4 to 6 units (1000–1500 ml) given over 1 to 2 hours can be used to replace coagulation factors. Coagulation parameters should be monitored to document effect and determine the timing and need for additional units.
- Dysfibrinogenemia or hypofibrinogenemia should be suspected if coagulation assays do not correct with FP or fibrinogen levels are low, respectively. Replacement can be attempted with 10 to 20 units of cryoprecipitate while following laboratory results.
- Patients who are intravascularly overloaded or who do not respond to FP should be considered for rFVIIa. Low doses of rFVIIa (25-50 μg/kg) are generally used, and repeated doses may be required because of the short rfVIIa half-life of 2 to 3 hours. rFVIIa may be most suitable as a temporizing measure to enable invasive procedures or hemostasis to be achieved by other means. Avoid use in the setting of DIC.

CBC, Complete blood count; *DIC,* disseminated intravascular coagulation; *FDP,* Fibrin degradation products; *FP,* frozen plasma; *INR,* international normalized ratio; *PT,* prothrombin time; *PTT,* partial thromboplastin time; *rFVIIa*. recombinant factor VIIa.

TABLE 3 Child-Pugh Staging Criteria

CHILD-PUGH SCORE			
Criteria	**1 Point**	**2 Points**	**3 Points**
Total serum bilirubin (mg/dl)	<2	2-3	>3
Serum albumin (g/dl)	>3.5	2.8-3.5	<2.8
INR	<1.70	1.71-2.20	>2.20
Ascites	No ascites	Ascites controlled	Ascites not controlled
Encephalopathy	No encephalopathy	Encephalopathy controlled	Encephalopathy not controlled
INTERPRETATION OF CHILD-PUGH SCORES			
	Points	**Life Expectancy**	**Perioperative Mortality**
Child Class A	5-6	15-20 yr	10%
Child Class B	7-9	Candidate for liver transplant	30%
Child Class C	10-15	1-3 yr	82%

INR, International normalized ratio.

- PPI use, but not H_2RA use, is associated with risk for serious infections in patients with decompensated cirrhosis.
- In patients with compensated cirrhosis and clinically significant hypertension beta-blockers reduced a composite of decompensation or death.[1]

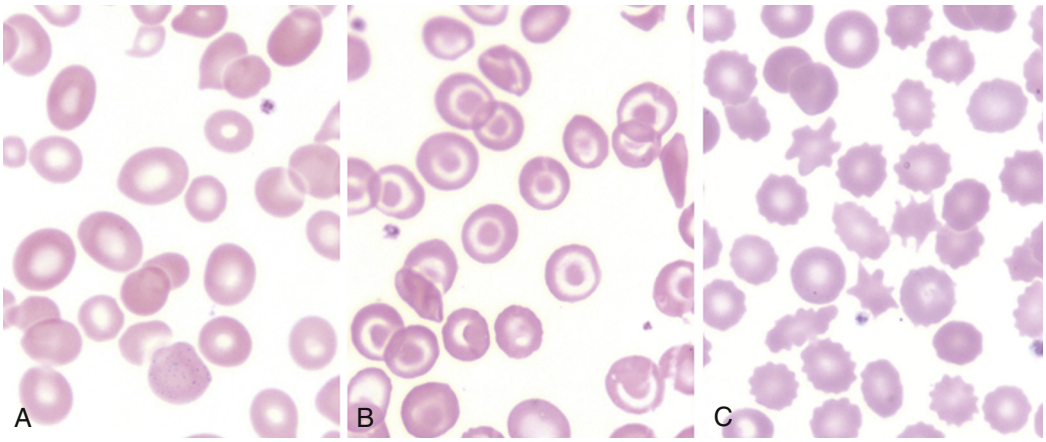

FIG. E1 Red blood cell morphology in liver disease. A, Macrocytes have a mean corpuscular volume greater than 100 fl and can be oval-shaped. Commonly associated disorders include liver disease and vitamin B_{12} and folate deficiency. **B,** Target cells are characterized by the bull's-eye appearance of the red blood cell (RBC). They are a result of an increased surface-to-volume ratio related to excess RBC membrane (e.g., liver disease) or disproportionate reduction of cytoplasmic content (e.g., hemoglobinopathies, iron deficiency). **C,** Acanthocytes, or spur cells, typically appear as contracted RBCs lacking central pallor with multiple irregular membrane projections. The morphologic appearance reflects the irreversible cytoskeletal damage that has occurred because of passage of nondeformable RBCs through the reticuloendothelial system. They are most commonly seen in severe liver disease but can also be features of rare neuroacanthocytosis syndromes or lipoprotein disorders. (From Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.)

Cirrhotic Cardiomyopathy

BASIC INFORMATION

DEFINITION

- Cirrhotic cardiomyopathy (CCM) is a clinical syndrome in cirrhotic patients characterized by impaired contractile responsiveness to stress and/or altered diastolic relaxation with electrophysiological abnormalities in the absence of other known cardiac disease.
- CCM is a separate clinical entity from alcoholic cardiomyopathy.

SYNONYM

CCM

ICD-10CM CODE

I43 Cardiomyopathy in diseases classified elsewhere

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE AND PREVALENCE:

- Prevalence between 40% to 50% in cirrhotic patients independent of liver disease etiology and 3% to 23.4% of patients undergoing orthotopic liver transplantation.
- Cardiac dysfunction is seen in 50% of patients with advanced cirrhosis.
- Heart failure is seen in 7% to 21% of patients who undergo orthotopic liver transplantation.

RISK FACTORS:

- Moderate to severe cirrhosis (Child Pugh B or C) tends to have at least one feature of CCM. There is no direct correlation between the degree of liver cirrhosis (assessed by Child Pugh or MELD score) and CCM.
- Posttransjugular intrahepatic portosystemic shunt (TIPS): Shift of splanchnic blood into the heart via the artificial shunts overloads a noncompliant left ventricle, leading to overt heart failure.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical and physical features include:

- Symptoms and signs of heart failure: Reduced exercise capacity, dyspnea on exertion, tachycardia, edema, ascites, paroxysmal nocturnal dyspnea, pulmonary congestion, increased jugular venous pressure, and an S3 or S4 gallop.
- Electrophysiological disturbances: QTc interval prolongation (>440 msec), Torsade de pointes, chronotropic incompetence.

ETIOLOGY & PATHOPHYSIOLOGY

Etiology is multifactorial in patients with liver disease. Fig. E1 illustrates proposed pathophysiology of cirrhotic cardiomyopathy.

Mechanisms of cardiac dysfunction include the following:

- Increased catecholamines in cirrhotic patients eventually leads to the downregulation of β-adrenergic receptors resulting in attenuated inotropic and chronotropic function.

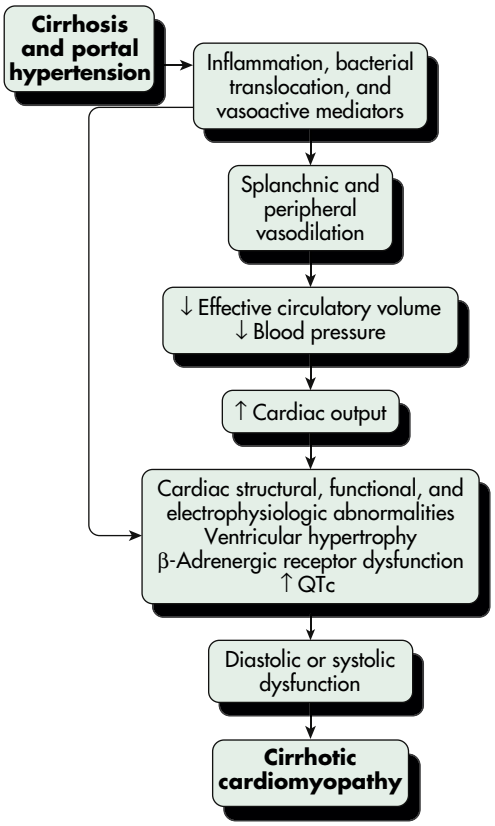

FIG. E1 Proposed pathophysiology of cirrhotic cardiomyopathy. *QTc,* Rate-corrected QT interval. (From Feldman M et al: *Sleisenger and Fortran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

- Inflammatory stimuli from nitric oxide, carbon monoxide, endocannabinoids, and cytokines, such as TNF-a, increase cardiomyocyte apoptosis.
- The decreased effective volume activates the renin–angiotensin–aldosterone system (RAAS), leading to fibrosis and stiff ventricles.
- Potassium channel defect leads to electrophysiological imbalances such as QT prolongation, chronotropic incompetence, and mechanical dyssynchrony.
- Hyperdynamic circulation: Increased volume expansion but poor volume distribution (increased splanchnic circulation, decreased central circulation) leads to relative hypovolemia, which activates the RAAS and sympathetic nervous system and leads to tachycardia and increased cardiac output.

DIAGNOSIS

The 2005 World Congress of Gastroenterology proposed the following criteria for CCM:

- Systolic dysfunction (LV EF <55%, blunted increase in cardiac output with exercise)
- Diastolic dysfunction on echocardiogram (E/A <1.0, deceleration time >200 msec, isovolumetric relaxation time >80 msec)
- Supportive criteria: Electromechanical abnormalities (prolonged QTc), heart chamber alterations (enlarged left atrium), humoral changes (increased brain natriuretic peptide [BNP], N-terminal pro-BNP [NT pro-BNP], or troponin)

DIFFERENTIAL DIAGNOSIS

- Alcoholic cardiomyopathy (ACM)
- Cardiac cirrhosis
- Iron-induced cardiac disease (hemochromatosis)
- Dilated cardiomyopathy
- Hypertrophic cardiomyopathy
- Restrictive cardiomyopathy
- Coronary atherosclerosis with left ventricular dysfunction

WORKUP

- BNP and NT pro-BNP: Markers of fluid overload, can correlate with the severity of cirrhosis
- Troponin I or T: Assess cardiac ischemia, increased LV mass

IMAGING STUDIES

- Electrocardiography: QTc >440 msec, ST depressions, bundle branch block
- Chest x-ray: Pulmonary congestion, left atrial and ventricular enlargement
- Echocardiogram: Resting systolic dysfunction; diastolic dysfunction (E/A <1, prolonged deceleration time [>200 msec] and prolonged isovolumetric relaxation time [>80 msec]); tissue Doppler imaging and speckle tracking echocardiography can quantitate the LV function
- MRI: Morphological evaluation of the liver and the heart (shunts, chamber quantification, tissue characterization)

DIAGNOSTIC TESTS

- Exercise testing (upright bicycle ergometry): Suppressed increase in cardiac output with exercise
- Dobutamine stress echocardiography (DSE): Lack of contractile reserve with dobutamine defined as an increase in LV EF <10% and or diastolic dysfunction. DSE has limited utility due to downregulated β-receptors)

Rx TREATMENT

There are no well-established guidelines for the management of CCM. Management should follow the same guidelines as in noncirrhotics.

NONPHARMACOLOGIC THERAPY

- Risk-factor modification: Weight loss, smoking cessation, exercise, blood pressure control
- Oxygen supplementation if signs of hypoxia
- Dietary sodium restriction (<2 g/day)
- Fluid restriction when serum sodium <120 mmol/L
- Pneumococcal and influenza vaccination

ACUTE GENERAL Rx

- Acute pulmonary edema: Head elevation ≥30 degrees, early diuretic use (furosemide, bumetanide, torsemide); nitrates are useful if concomitant hypertension or chest pain
- Cardiogenic shock: Inotropes (dobutamine, milrinone), vasopressors (norepinephrine, dopamine), and mechanical support if needed

CHRONIC Rx

Chronic management is consistent with the treatment of patients with heart failure.

- Diuretics: Furosemide and spironolactone are the mainstay for treating fluid overload in cirrhosis.
- Beta-blockers: They promote the reduction of the QT interval. Nonselective beta-blockers are known to prevent variceal bleeding. One should exercise caution because beta-blockers can reduce cardiac output.
- Liver transplantation is the cure for cirrhosis and its associated cardiomyopathy. It has been shown to restore exercise capacity within 6 to 12 months.

DISPOSITION

- Mortality rate is unclear because most patients die from repercussions of liver failure.
- Liver transplant can reverse CCM features, including systolic and diastolic dysfunction and QT prolongation.
- Patients with diastolic dysfunction have worse prognosis after liver transplantation.

REFERRAL

Follow-up with a cardiologist is recommended.

PEARLS & CONSIDERATIONS

COMMENTS

- CCM should be considered in cirrhotic patients who present with symptoms and signs of heart failure symptoms or arrhythmia.
- Diagnostic criteria are based on echocardiogram (systolic or diastolic dysfunction), stress testing, electrophysiological disturbances, and laboratory abnormalities.
- Liver transplantation is the definitive treatment for this rare clinical entity.

PREVENTION

Treatment of liver disease prior to progression to cirrhosis.

PATIENT & FAMILY EDUCATION

A multidisciplinary team involving a hepatologist and cardiologist may be useful in long-term management and patient education.

BASIC INFORMATION

DEFINTION

Claudication refers to reproducible pain, fatigue, discomfort, or cramping due to vascular origin in a muscle group that is consistently induced by exertion and is relieved with rest. Claudication results from inadequate blood flow to the target muscle group, which is not able to meet increased metabolic demand, resulting in a supply-and-demand mismatch due to peripheral arterial disease (PAD). Intermittent vascular claudication is more common in the lower extremities but can also affect the upper extremities.

SYNONYM

Intermittent claudication

ICD-10CM CODES

I70.211	Atherosclerosis of native arteries of extremities with intermittent claudication, right leg
I70.212	Atherosclerosis of native arteries of extremities with intermittent claudication, left leg
I70.213	Atherosclerosis of native arteries of extremities with intermittent claudication, bilateral legs
I70.219	Atherosclerosis of native arteries of extremities with intermittent claudication, unspecified extremity
I70.311	Atherosclerosis of unspecified type of bypass graft(s) of the extremities with intermittent claudication, right leg
I70.312	Atherosclerosis of unspecified type of bypass graft(s) of the extremities with intermittent claudication, left leg
I70.313	Atherosclerosis of unspecified type of bypass graft(s) of the extremities with intermittent claudication, bilateral legs
I70.319	Atherosclerosis of unspecified type of bypass graft(s) of the extremities with intermittent claudication, unspecified extremity
I70.719	Atherosclerosis of other type of bypass graft(s) of the extremities with intermittent claudication, unspecified extremity

EPIDEMIOLOGY & DEMOGRAPHICS

- Symptomatic claudication in Western countries affects 5% of patients between the ages of 55 and 74.
- Lower extremity PAD, which includes both symptomatic claudication and asymptomatic disease, is estimated to affect approximately 8.5 million Americans above age 40 and 202 million people around the world.
- At-risk patients include:
  1. All patients age 65 yr or older.
  2. Age 50 to 64 yr with risk factors for atherosclerosis, including diabetes mellitus, smoking history, hyperlipidemia, hypertension, or family history of PAD.
  3. Age <50 yr, with diabetes mellitus and one additional risk factor for atherosclerosis.
  4. Individuals with known atherosclerotic disease in another vascular bed, for example, coronary, carotid, subclavian, renal, mesenteric artery, or abdominal aortic aneurysm (AAA).
- Risk factors associated with development of PAD are similar to coronary atherosclerosis (CAD) and include increasing age, cigarette smoking (odds ratio 2.72), hypertension (odds ratio 1.55), diabetes mellitus (odds ratio 1.88), and hypercholesterolemia (odds ratio 1.19). In addition, patients with chronic kidney disease, metabolic syndrome, and elevated levels of C-reactive protein, lipoprotein(a), and homocysteine are at increased risk. Nontraditional risk factors include race/ethnicity, with African American patients being at higher risk. Hispanics also have similar to slightly higher rates of PAD compared to non-Hispanic whites.
- There is a strong correlation among PAD, CAD, carotid artery stenosis, and generalized cerebrovascular disease. Individuals with known atherosclerotic disease in one vascular bed are likely to have disease in another.
- The American College of Cardiology/American Heart Association (ACC/AHA) guidelines suggested the following distribution of clinical presentation of PAD in patients 50 yr of age or older:
  1. Asymptomatic: 20% to 50%
  2. Atypical leg pain: 40% to 50%
  3. Classic intermittent claudication: 10% to 35%
  4. Critical limb ischemia with threatened limb: 1% to 2%

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The severity of symptoms varies with degree of PAD, collateral blood supply, and exertional demands
- Classic symptoms include exertional calf pain, which limits the patient's activity and self-resolves with rest within 10 minutes. Claudication can also typically present in the buttock and hip, thigh, calf, or foot, with one or more of the following signs or symptoms, depending on the level and degree of peripheral stenosis:
  1. Diminished or absent pedal pulses
  2. Bruit over the distal aorta, iliac, or femoral arteries
  3. Pallor of the distal extremities and cool to the touch upon elevation
  4. Rubor with prolonged capillary refill upon dependent positioning
  5. Trophic changes, including hair/nail loss and muscle atrophy
  6. Nonhealing ulcers, necrotic tissue, and gangrene
  7. Weakness, numbness, or heaviness in the lower extremities
- True vascular claudication must be distinguished from "pseudoclaudication," which can be caused by severe venous obstruction or insufficiency, chronic compartment syndrome, spinal stenosis, osteoarthritis, and inflammatory muscle diseases. The characteristic features of pseudoclaudication that distinguish it from claudication are summarized in Table 1. Table 2 illustrates the differential diagnosis of intermittent claudication
- Location of pain usually corresponds to analogous anatomy:
  1. Buttock and hip: Aortic or iliac disease
  2. Thigh: Aorta, iliac, or common femoral artery
  3. Upper two thirds of calf: Superficial femoral artery
  4. Lower one third of calf: Popliteal artery
  5. Foot: Tibial or peroneal artery
- Asymptomatic PAD is typically diagnosed by screening studies (exercise ankle brachial index, lower-extremity ultrasound) or incidentally on physical exam. Patients who are at significant risk for PAD often have multiple comorbidities that can alter their presentation. In the PARTNERS program report, 47% of those with a new diagnosis of PAD had no history of leg symptoms, 47% had atypical symptoms, and only 6% had classic symptoms
- Symptoms of intermittent claudication classically start distally within a muscle group (below the stenosis) and then ascend with continued activity
- Rest pain that occurs with leg elevation and is paradoxically relieved by walking may suggest severe PAD
- Critical limb ischemia may present as tissue ulceration and gangrene, which require prompt intervention

ETIOLOGY

The primary cause of claudication is peripheral atherosclerosis, resulting in a stenosis that impedes blood flow beyond the level necessary to meet the metabolic demand of limb muscles first with activity and then ultimately at rest.

TABLE 1 Characteristic Features of Pseudoclaudication that Distinguish It from Claudication

	Claudication	Pseudoclaudication
Characteristics	Limb cramping, tightness, fatigue	Similar to claudication with numbness
Location of discomfort	Lower extremity involving buttock, hip, thigh, calf, foot	Similar to claudication
Induced by exercise	Yes	Variable
Reproducible with distance walked	Consistent	Variable
Occurs with standing	No	Yes
Actions which provide relief	Stand	Sit
Time to relief	<5 min	≥30 min

TABLE 2 Differential Diagnosis of Intermittent Claudication

	Intermittent Claudication	Venous Claudication	Neurogenic Claudication
Quality of pain	Cramping	Aching, heaviness, tightness	"Pins and needles" sensation going down the leg, weakness
Onset	Gradual, consistent	Gradual; can, however, be immediate	Can be immediate
Relieved by	Stopping walking	Activity, elevation of leg	Sitting down, stooping, flexion at the waist
Location	Muscle groups (e.g., buttocks, thigh, calf)	Entire leg, worse in calf	Poorly localized, but can affect whole leg
Legs affected	Usually one	Usually one	Often both

From Swartz MH: *Textbook of physical diagnosis,* ed 7, Philadelphia, 2014, Saunders.

Other etiologies include neuropathy, musculoskeletal or degenerative disease, compartment or entrapment syndrome, vasculitis, and embolic events.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Spinal stenosis (neurogenic or pseudoclaudication)
- Musculoskeletal disorders: Arthritis or myositis
- Degenerative osteoarthritic joint disease, predominantly of the lumbar spine and hips
- Chronic compartment or popliteal artery entrapment syndrome
- Peripheral neuropathy
- Atheromatous embolization and deep venous thrombosis
- Vasculitis: Thromboangiitis obliterans, Takayasu, or giant cell arteritis
- Symptomatic Baker cyst
- Venous claudication

WORKUP

History and physical findings suggest the diagnosis of claudication and noninvasive studies help confirm the diagnosis.

- Careful physical examinations include:
  1. Measurement of blood pressure in both arms and notation of asymmetry.
  2. Palpation and recording of carotid pulses, upstroke, amplitude, and presence of bruits.
  3. Auscultation and palpation of abdomen for bruits, aortic pulsation, and diameter.
  4. Palpation of brachial, radial, ulnar, femoral, popliteal, dorsalis pedis, and posterior tibial pulses. Pulse intensity should be recorded as follows: 0, absent; 1+, diminished; 2+, normal; 3+, bounding.
  5. Auscultation of femoral arteries for the presence of bruits.
  6. Extremities should be inspected for color, temperature, integrity of the skin, hair loss, and hypertrophic nails.
- Measurement of resting ankle–brachial index (ABI) should be considered first-line test in patients at risk for PAD.
- An ABI is the ratio of higher ankle systolic pressure (between the dorsalis pedis and posterior tibial arteries) of each leg to the higher systolic pressure of either arm (brachial artery).
- The severity of PAD is based on the resting ABI:
  1. Abnormal: ≤0.90
  2. Borderline: 0.91 to 0.99
  3. Normal: 1.00 to 1.40
  4. Noncompressible: >1.40
- ABI ≤0.90 has 75% sensitivity and 86% specificity in the detection of PAD.
- A low ABI has been shown to be an independent predictor of mortality.
- A high ABI (>1.4) may represent significant PAD caused by heavy calcification. In such cases, measuring a toe–brachial index (TBI) can increase the sensitivity of testing, as highly calcified arteries are incompressible and may have an elevated ABI. A toe–brachial index <0.7 is considered abnormal and diagnostic of PAD.
- Borderline resting ABI (>0.90 and ≤1.40) in patients with exertional leg symptoms should undergo exercise treadmill ABI testing to evaluate for PAD. This can help differentiate claudication from pseudoclaudication. If post-treadmill ABI is normal, alternative causes of leg pain should be considered.
- Progression of PAD is considered to have occurred if a decrease in ABI of 0.15 occurs while the patient is on treatment.
- If a patient has a history concerning for PAD but a normal ABI, and if the clinician is concerned about a potential false-negative finding, performing an exercise stress ABI can potentially demonstrate lower-extremity PAD.
- If after exercise, ABI reading decreases by more than 20% or an ankle pressure decreases by 30 mm Hg, the patient should be considered to have significant PAD.
- Segmental systolic pressures are measured at the level of the thigh, calf, ankle, metatarsal, and toes. Normally, successive segments have <20 mm Hg difference in pressures. If the gradient is >20 mm Hg, a significant stenosis is suspected in the interval vascular segment.

IMAGING STUDIES

- Duplex ultrasound can be used to assess occlusion location, length, and patency of the distal arterial system or prior grafts; it is a good choice for initial imaging and surveillance monitoring after revascularization.
- In patients with prior infra-inguinal venous bypass grafts, the long-term patency should be evaluated at regular intervals using a duplex ultrasound approximately 4 to 6 wk post procedure, 6 and 12 mo after graft placement, and then yearly.
- Magnetic resonance angiography (MRA) and CT angiography (CTA) are effective for imaging of the aorta and peripheral lower-extremity arteries above the knee. MRA has almost replaced catheter-based angiography, with 90% sensitivity and 97% specificity in identification of hemodynamically significant stenosis in the lower extremities.
- MRA and CTA are useful to define the anatomy and assist in planning percutaneous and surgical revascularization; however, the utility of each is decreased by necessity of gadolinium contrast and noniodinated contrast agents, respectively.
- Angiography (Fig. 1) remains the gold standard for diagnosing PAD, particularly below the knee.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Smoking cessation is of paramount importance. Smokers and former smokers should be asked about tobacco use status at every visit and offered pharmacotherapy, counseling, and/or referred to smoking cessation programs.
- Aggressive risk factor modification for hypertension, dyslipidemia, and diabetes mellitus, including diet, weight loss, and lifestyle counseling, is recommended (Fig. 2).
- Supervised exercise training should be performed as a first-line therapy for a minimum of 30 to 45 minutes, in sessions performed at least 3 times per wk, for a minimum of 12 wk.
- Supervised exercise training programs under direct supervision in a hospital or outpatient facility and structured exercise are recommended for all patients with PAD. This has been shown to increase maximal walking distance, pain-free walking distance, and the 6-minute walking distance. It typically requires 4 to 6 wk for patients to notice improvement.
- Structured or home-based walking exercise program may be considered as an alternative treatment modality, but it has not been shown to be as efficacious. It can be combined with group-mediated cognitive behavioral intervention that can significantly

FIG. 1 Angiogram of the distal abdominal aorta and iliac arteries demonstrates an occluded left common iliac artery with extensive collateral circulation from contralateral internal iliac artery *(left panel),* which resolved after successful stent implantation *(right panel).* (Images courtesy of Bart Domatch, MD, Radiology Department, University of Texas Southwestern Medical Center, Dallas, Texas; From Andreoli TE et al: *Andreoli and Carpenter's Cecil essentials of medicine,* ed 8, Philadelphia, 2010, Saunders.)

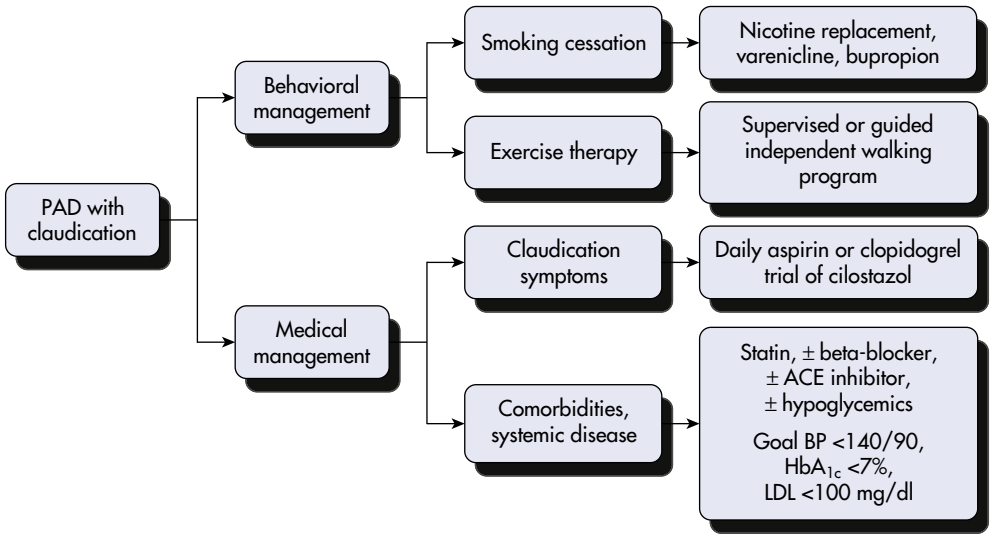

FIG. 2 Algorithm for revascularization in the management of claudication. *ACE*, Angiotensin-converting enzyme; *BP*, blood pressure; *HbA_{1c}*, hemoglobin A_{1c}; *LDL*, low-density lipoprotein; *PAD*, peripheral arterial disease. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

improve endurance and physical activity for patients unable or unwilling to participate in supervised exercise training.
- Lifestyle therapy in conjunction with exercise can be as, or more, effective than pharmacologic therapy and in some cases more effective than stent revascularization.
- Intermittent mechanical compression appears to be an effective noninvasive treatment alternative for patients with intermittent claudication.

ACUTE GENERAL Rx

Revascularization by an endovascular or surgical approach is usually reserved for patients with symptoms refractory to medical therapy or those with impending critical limb ischemia.

CHRONIC Rx

- Aspirin 75 to 325 mg daily is standard therapy.
- Thienopyridine medications such as clopidogrel 75 mg daily may be considered as an alternative to aspirin, especially for those intolerant of aspirin.
- Current data do not support combination treatment with aspirin and clopidogrel.
- Asymptomatic patients with PAD (ABI ≤0.90) without claudication symptoms may benefit from the addition of an antiplatelet agent, either ASA or clopidogrel, as there is an increased cardiovascular risk in this subgroup.
- Statin medications are indicated for all patients with PAD.
  1. LDL cholesterol level of less than 100 mg/dl is recommended.
  2. A goal LDL cholesterol level of less than 70 mg/dl is recommended for patients with PAD and high risk for coronary atherosclerotic disease.
  3. Although new lipid guidelines have been published, the guidelines did not specifically address patients with PAD; therefore, the numerical targets can be considered. In those unable to reach the targets, a reduction in LDL >50% should be approached at a minimum.
- Antihypertensive therapy with beta-adrenergic blocking drugs and/or ACE inhibitors should be administered to all hypertensive patients with PAD to reduce the risk of MI,

stroke, congestive heart failure, and cardiovascular death.
- Cilostazol 100 mg bid may be used in conjunction with aspirin or clopidogrel. It has been shown to increase walking distance by 50% to 67% in symptomatic patients.
- Among patients with intermittent claudication, a single randomized controlled trial has shown a 24-wk treatment with ramipril resulted in significant increases in pain-free and maximum treadmill walking times compared with placebo.
- Pentoxifylline is not effective for treatment of claudication. In a review of 24 studies with over 3000 participants, results remained unclear, and a randomized control trial showed no difference between pentoxifylline and placebo; thus this is not recommended as a treatment for claudication.
- In patients with type II diabetes, a secondary analysis of the BARI 2D trial showed that an insulin-sensitizing approach (metformin, glitazones) reduces the risk of developing PAD when compared to insulin-providing therapy (glipizide, insulin). These patients also have lower rates of revascularization and amputation.
- Patients who are tobacco smokers should be strongly advised to quit smoking at every visit and offered either varenicline or bupropion along with nicotine replacement therapy in the absence of any contraindications. Patients with PAD should avoid tobacco smoke exposure at work, at home, and in public places.
- Anticoagulation should not be used to reduce the risk of cardiovascular ischemic events in patients with PAD as there is increased morbidity with no mortality benefit. Its use to improve patency after bypass is uncertain.
- Novel agents, such as protease-activated receptor-1 (e.g., vorapaxar), added to existing antiplatelet therapy may have some benefit in decreasing acute limb-related ischemic events; however, its association with a risk of moderate to severe bleeding makes its benefits uncertain at this time.
- Fig. 3 summarizes the nonoperative management of claudication.
- Revascularization through either a percutaneous or surgical approach is indicated in patients with lifestyle-limiting claudication and inadequate response to goal-directed medical therapy. It is also indicated in those with nonhealing ulcers or gangrene and in select patients with functional disability. Before such revascularization, each patient should have:
  1. Participated in a supervised exercise training program and been given goal-directed medical therapy.
  2. Received comprehensive risk factor modification, including smoking cessation and optimal management of comorbidities.
  3. Significant disability with either the inability to perform normal work or a serious impairment of other activities important to the patient.
  4. Lower-extremity PAD lesion anatomy amenable to revascularization defined as low risk with high probability of initial and long-term success.
- Common procedures include:
  1. Aorto-iliofemoral reconstruction or bypass or infrainguinal bypass (e.g., femoropopliteal, femorotibial).
  2. Percutaneous balloon angioplasty, often with stenting, is primarily used on discrete stenotic lesions in the iliac or femoropopliteal arteries.

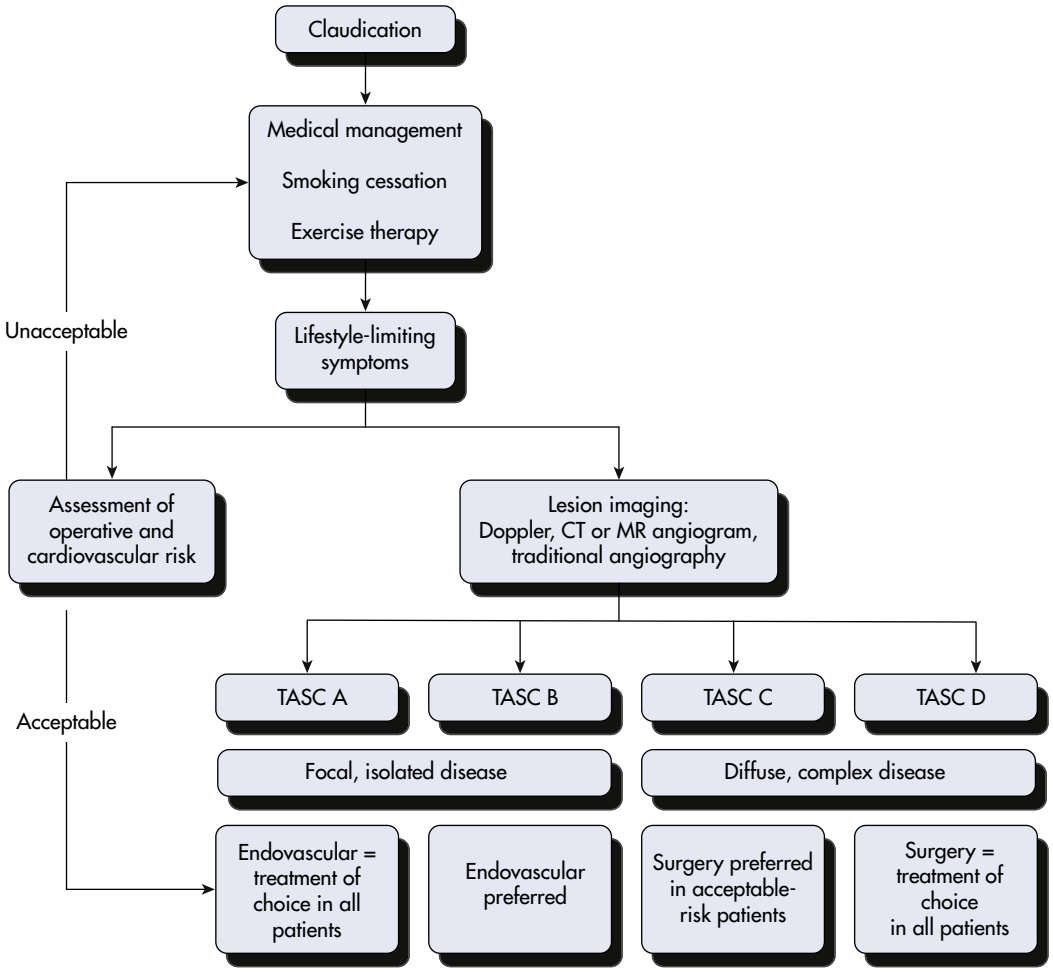

FIG. 3 Nonoperative management of claudication. *CT*, Computed tomographic; *MR*, magnetic resonance; *TASC*, TransAtlantic Inter-Society Consensus class. (From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.)

3. Endovascular intervention is recommended as the preferred revascularization technique for iliac and femoropopliteal arterial lesions.
4. Stenting is an effective primary therapy for common and external iliac artery stenosis and occlusions. However, it is not recommended in the femoral, popliteal, or tibial arteries due to a low success rate except to salvage suboptimal balloon dilation.

- Endovascular procedures should not be performed in patients with PAD solely to prevent progression to critical limb ischemia, as reported rates of amputation or progression to critical limb ischemia are <10% to 15% over 5 yr or more, and increased mortality rate associated with claudication is usually the result of cardiovascular events rather than limb-related events.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- A meta-analysis found that over 12 to 24 wk, *Ginkgo biloba* increased pain-free walking distance by 34 m compared with placebo, although the benefit is not well established according to ACC/AHA guidelines.
- Naftidrofuryl, a serotonin receptor inhibitor, available in Europe and other parts of the world, has shown some efficacy in improving claudication symptoms.
- Estrogen replacement therapy, propionyl-L-carnitine, L-arginine, oral vasodilators, prostaglandins, and chelation therapy are ineffective in the treatment of intermittent claudication.
- B-complex vitamin supplementation to lower homocysteine levels for prevention of cardiovascular events in patients with PAD is not recommended (HOPE-2 trial).
- Acupuncture has shown some improvement in symptom relief and functional capacity in small studies but mainly in neurogenic claudication or mild peripheral arterial disease.

DISPOSITION

- It is unusual for intermittent claudication to progress to ischemic leg or limb loss, especially with aggressive use of conservative treatments, risk factor modification, exercise, and smoking cessation.
- The 5-yr risk for development of ischemic ulceration in patients treated for diabetes and with ABI <0.5 was 30% compared with only 5% in patients without either characteristic.
- A screening duplex ultrasound for AAA is recommended for patients with symptomatic PAD.
- All patients with PAD should receive annual influenza vaccination based on observational studies that have demonstrated a reduced cardiovascular event rate.

REFERRAL

Consultation with physicians specializing in vascular medicine is recommended for patients with threatened limb loss, rest pain, nonhealing ulcers, functional disability from pain, and gangrene.

PEARLS & CONSIDERATIONS

- Approximately 70% of patients with peripheral vascular disease will have concomitant coronary artery disease.
- Beta-blockers may worsen claudication symptoms in some patients, although their underuse is associated with excess cardiovascular death. Patients with intermittent claudication are less likely to receive beta-blocker therapy after a myocardial infarction. Those who do not receive post-MI beta-blockers have at least a three-fold higher mortality.
- Patients with peripheral vascular disease may benefit from secondary cardiovascular prevention with clopidogrel versus aspirin more so than other high-risk patients.
- Often, PAD can be asymptomatic or with atypical symptoms, and a thorough history, physical exam, and clinical suspicion based on medical comorbidities may help guide therapy before lifestyle-limiting claudication or limb ischemia develops.

COMMENTS

- Claudication is a marker for generalized atherosclerosis. Patients have a higher risk of death from cardiovascular events than from limb loss. Patients with PAD experience diminished overall quality of life similar to patients diagnosed coronary artery or cerebrovascular disease.
- The ABI is more closely associated with exercise tolerance and severity of disease in persons with PAD rather than intermittent claudication or other leg symptoms.

BASIC INFORMATION

DEFINITION

Clostridium difficile infection (CDI) is the occurrence of diarrhea and bowel inflammation associated with antibiotic use caused by *C. difficile*, an anaerobic gram-positive, spore-forming, toxin-producing bacillus transmitted through the fecal–oral route. CDI can manifest clinically in several forms ranging from fulminant diarrhea and leukocytosis associated with pseudomembranous colitis, mild to severe acute diarrhea, short-term colonization seen typically in health care facilities, and recurrent CDI within 60 days after initial treatment occurring in 20% to 30% of cases.

SYNONYMS

Antibiotic-induced colitis
Pseudomembranous colitis
CDI

ICD-10CM CODE
A04.7 Enterocolitis due to *Clostridium difficile*

EPIDEMIOLOGY & DEMOGRAPHICS

- Cephalosporins are the most frequent offending agent in CDI because of their high rates of use.
- The antibiotic with the highest incidence is clindamycin (10% incidence of CDI with its use).
- Since 1996, the incidence of CDI has more than doubled. Severity of CDI has also increased due to the emergence of an epidemic virulent strain (NAP1/BI/027). CDI is the most common infectious cause of health-care–associated diarrhea in adults. In the U.S. *C. difficile* is responsible for nearly half a million infections per year and is associated with approximately 29,000 deaths/year.
- Nosocomial CDI quadruples the cost of hospitalizations and increases annual expenditures by $4 and $6 billion in the U.S.
- Asymptomatic carriage of *C. difficile* is identified in more than 20% of patients hospitalized without diarrhea.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Abdominal tenderness (generalized or lower abdominal)
- Fever
- In patients with prolonged diarrhea, poor skin turgor, dry mucous membranes, and other signs of dehydration may be present

ETIOLOGY

C. difficile colonizes the large intestines and releases two protein exotoxins (TcdA and TcdB) that cause colitis. Infection is transmitted by spores that are resistant to antibiotics, heat, and acid. The NAP1 strain is predominant among patients with *C. difficile* infection, whereas asymptomatic patients are more likely to be colonized with other strains. Risk factors for *C. difficile* (the major identifiable agent of antibiotic-induced diarrhea and colitis):

- Administration of antibiotics: Can occur with any antibiotic, but occurs most frequently with clindamycin, ampicillin, cephalosporins, and fluoroquinolone
- Prolonged hospitalization
- Advanced age
- Abdominal surgery
- Underlying disease (malignancy, renal failure, debilitated status)
- Hospitalized, tube-fed patients are at risk for *C. difficile*–associated diarrhea. Clinicians should consider testing for *C. difficile* in tube-fed patients with diarrhea unrelated to the feeding solution
- Proton pump inhibitor (PPI) and H_2 blocker therapy increases risk of CDI and recurrent CDI. Risk is 1.7-fold higher with PPIs

DIAGNOSIS

The clinical signs of CDI generally include diarrhea, fever, and abdominal cramps after use of antibiotics. Although a history of recent antibiotic use is common, it is not a requirement for diagnosis.

DIFFERENTIAL DIAGNOSIS

- Gastrointestinal bacterial infections (e.g., *Salmonella, Shigella, Campylobacter, Yersinia*)
- Enteric parasites (e.g., *Cryptosporidium, Entamoeba histolytica*)
- Inflammatory bowel disease
- Celiac sprue
- Irritable bowel syndrome
- Ischemic colitis
- Antibiotic intolerance

WORKUP

- All patients with diarrhea accompanied by current or recent antibiotic use should be tested for *C. difficile* (see later discussion). *C. difficile* stool tests are positive in 3% of outpatients and up to 29% of inpatients without signs of infection. Testing and treatment for CDI is not recommended in asymptomatic individuals.
- Sigmoidoscopy (without cleansing enema) may be necessary when the clinical and laboratory diagnosis is inconclusive and the diarrhea persists.
- In antibiotic-induced pseudomembranous colitis, the sigmoidoscopy often reveals raised white-yellow exudative plaques adherent to the colonic mucosa pseudomembranes. These are seen more commonly in severe CDI.

LABORATORY TESTS

- Stool test for *C. difficile* toxin: Enzyme-linked immunosorbent assay for *C. difficile* toxins A and B. The latter is used most widely in the clinical setting. It has a sensitivity of 85% and a specificity of 100%.
- *C. difficile* toxin can be detected by cytotoxin tissue culture assay (cytotoxin assay, gold standard for identifying *C. difficile* toxin in stool specimen). This test is difficult to perform, and results are not available for 24 to 48 hr.
- Fecal leukocytes (assessed by microscopy or lactoferrin assay) are generally present in stool samples.
- Complete blood count usually reveals leukocytosis. A sudden increase in white blood cells to >30,000/mm^3 may be indicative of fulminant colitis.
- Laboratory indicators of **severe CDI** are leukocyte count >15,000/mm^3, serum creatinine ≥1.5 times baseline level, serum albumin <2.5 g/dl.

IMAGING STUDIES

- Abdominal film (flat plate and upright) is useful in patients with abdominal pain or evidence of obstruction on physical examination.
- CT can demonstrate typical findings of colonic wall thickening, dilatation, and the so-called *accordion sign* (thickened haustral folds and trapped contrast material, ascites, or pericolonic stranding [Fig. 1]).

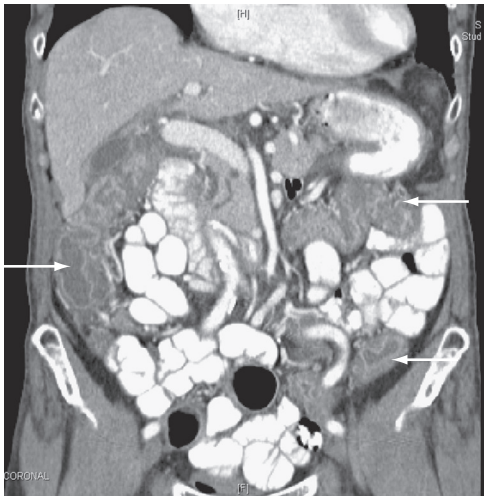

FIG. 1 Computed tomography with oral and intravenous contrast in a patient with *Clostridium difficile* colitis. Typical findings include colonic wall thickening *(arrows)*, dilation, and accordion sign (thickened haustral fold and trapped contrast material, ascites, and pericolonic stranding). (From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Discontinue offending antibiotic.
- Fluid hydration and correction of electrolyte abnormalities.
- Probiotics to restore natural defense mechanisms may be useful as adjuvant therapy; however, evidence is limited. Probiotic trials have failed to show benefit in preventing *C. difficile*–associated diarrhea.
- Fecal microbiota transplantation (FMT) is an excellent treatment modality for recurrent CDI. It replaces the altered gut flora to allow colonization resistance. Trials have shown that it is more effective than vancomycin and may become standard treatment for recurrent CDI. Recent trials have shown that donor stool administered via colonoscopy are safe and more efficacious than autologous FMT in preventing further CDI episodes.

ACUTE GENERAL Rx

- Vancomycin 125 mg PO qid for 10 days can be used as initial treatment in patients with nonsevere or severe CDI. Patients with fulminant CDI will require 500 mg qid for 10 days.
- Fidaxomicin 200 mg bid for 10 days has shown noninferiority to vancomycin and a lower rate of CDI recurrence (25% with vancomycin vs. 15% with fidaxomicin); however, its higher cost is a limiting factor. Fidaxomicin can be used for initial treatment of nonsevere or severe CDI or for recurrence of CDI if vancomycin was used for initial treatment.
- Metronidazole 500 mg PO qid for 10 days can be used in patients with mild disease if oral vancomycin or fidaxomicin are not available or contraindicated. A significant rise in clinical failure has been seen with metronidazole over the past decade, especially in patients with the BI/NAP/027 strain.
- When parenteral therapy is necessary (e.g., patient with paralytic ileus), IV metronidazole 500 mg qid can be used. It can also be supplemented with vancomycin 500 mg by nasogastric tube with intermittent clamping or retention enema.
- Fecal microbiota transplantation (FMT): When standard treatment has failed, intestinal microbiota transplantation (IMT) is an effective alternative therapy (eradication rate is 94%). It involves infusing intestinal microorganisms (in a suspension of healthy donor stool) into the intestine of a sick patient via enema, oral capsule, gastroscope/colonoscope, or nasojejunal tube to restore the microbiota. In patients with recurrent C. difficile infection, FMT by oral capsule has been shown to be noninferior to transplantation by colonoscopy for recurrence at 12 weeks. Trials comparing fresh versus frozen fecal microbiota transplantation have shown equal efficacy.
- The human monoclonal antibody bezlotoxumab has been FDA-approved for use with antibacterial drug treatment to reduce recurrence of CDI. Cost is a limiting factor.

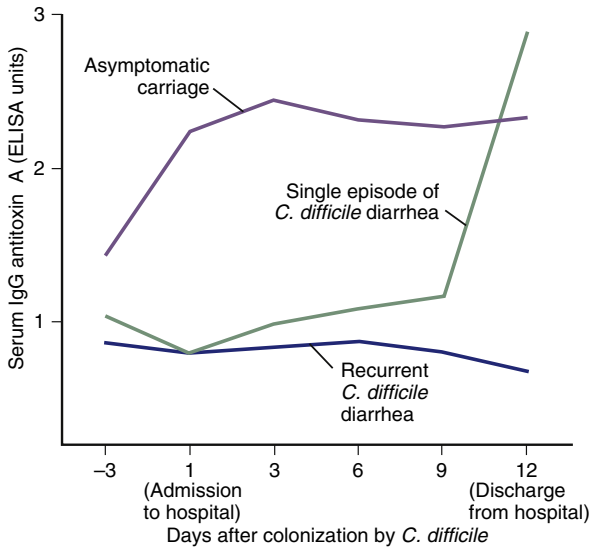

FIG. 2 Serum immunoglobulin G (IgG) antitoxin A antibody response and clinical outcome of infection with *Clostridium difficile*. Patients with nosocomial *C. difficile* diarrhea were studied prospectively, and serum IgG antitoxin A antibody concentrations were measured by enzyme-linked immunosorbent assay *(ELISA)* at regular intervals. A correlation was observed between the IgG response to toxin A and the clinical outcome of infection. Asymptomatic carriers mounted an early memory immune response to toxin A. By contrast, no significant increase was found in serum IgG antitoxin A of patients who experienced recurrent *C. difficile* diarrhea. In those who had a single episode of diarrhea, IgG antitoxin A levels generally were increased on day 12 of their first episode. Thus, a serum antibody response to toxin A during *C. difficile* infection is associated with protection against symptoms and against recurrent diarrhea. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

SURGICAL MANAGEMENT

- Indications: CDI unresponsive to medical therapy, fulminant colitis
- Clinical features: Colonic distention, severe abdominal pain/tenderness, systemic inflammatory response syndrome. Diarrhea may be absent because of ileus
- Surgical approaches:
  1. Traditional (subtotal or total colectomy), high mortality (50%)
  2. Colon-sparing (loop ileostomy with intraoperative colonic lavage using warmed polyethylene glycol solution via the ileostomy and instillations of postoperative vancomycin flushes via the ileostomy); lower mortality compared to traditional approach

CHRONIC Rx

- Judicious future use of antibiotics to prevent recurrences (e.g., avoid prolonged antibiotic therapy).
- Probiotics have been shown mildly effective in reducing the risk for CDI among patients prescribed antibiotics. They should not be used in immunocompromised or severely debilitated patients.
- Alcohol-based hand gels are inadequate for eradication of spores. They are inferior to soap and water for eradication of spores.
- Gastric acid suppression with PPIs increases risk of CDI. Preferential use of H_2RA should be considered in these patients.

DISPOSITION

- Most patients recover completely with appropriate therapy. Fever resolves within 48 hr and diarrhea within 4 to 5 days. Overall mortality rate is 1% to 2.5% but exceeds 10% in untreated patients. CDI recurrence after an initial episode is 20% to 25% regardless of initial treatment with metronidazole or vancomycin. Each recurrence increases risk of repeat episodes (65% chance of recurrence after three CDI episodes). Recurrent CDI usually represents relapse rather than reinfection, no matter how long between episodes (Fig. 2). Recurrent episodes are best treated with a prolonged course of oral vancomycin tapered off over several weeks to months.
- Hospital-acquired CDI is independently associated with an increased risk of in-hospital death. All hospitalized patients with CDI should be placed in contact isolation at least until resolution of diarrhea.

Cluster Headache PTG

BASIC INFORMATION

DEFINITION

The term *cluster headache* refers to attacks of severe, unilateral pain that is orbital, supraorbital, temporal, or any combination of these sites, lasting 15 to 180 minutes, and occurring from once every other day to eight times a day over a span of weeks to months. The attacks are associated with one or more ipsilateral signs and symptoms of parasympathetic activation: Conjunctival injection, lacrimation (Fig. 1), nasal congestion, rhinorrhea, forehead and facial sweating, miosis, ptosis, or eyelid edema. Most patients are restless or agitated during an attack.

SYNONYMS

Headache, cluster
Ciliary neuralgia
Erythromelalgia of the head
Erythroprosopalgia of Bing
Horton headache

ICD-10CM CODES

G44.001	Cluster headache syndrome, unspecified, intractable
G44.009	Cluster headache syndrome, unspecified, not intractable
G44.011	Episodic cluster headache, intractable
G44.019	Episodic cluster headache, not intractable
G44.021	Chronic cluster headache, intractable
G44.029	Chronic cluster headache, not intractable

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimated to occur in 0.05% to 1% of the population
PREDOMINANT SEX: Occurs in males at least five times more commonly than in females
PREDOMINANT AGE: Peak age of onset between 20 and 40 yr

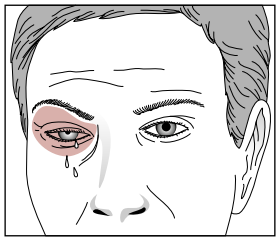

FIG. 1 This 43-year-old man with cluster headaches suffers from nightly right-sided unrelenting, severe, stabbing unilateral periorbital pain for 45 minutes to 3 hours accompanied by ipsilateral tearing and nasal discharge, along with ptosis and miosis (a partial Horner syndrome). Note that the ptosis prompts compensatory elevation of the eyebrow. (From Kaufman DM, et al.: *Kaufman's clinical neurology for psychiatrists*, ed 8, Philadelphia, 2017, Elsevier.)

GENETICS: May be inherited in up to 20% of cases, although uncertainty exists over the mode or modes of inheritance.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Many of the attacks are nocturnal and some may be provoked by alcohol ingestion.
- During attack: Conjunctival injection, lacrimation, nasal congestion, rhinorrhea, facial sweating, Horner syndrome.
- In contrast to migraine sufferers, patients are agitated and active during an attack.
- Symptoms associated with an attack remain ipsilateral during the attack but may switch sides from one attack to the next.
- Permanent partial Horner syndrome in 5% of patients; otherwise examination is normal.

ETIOLOGY

Activation of the posterior hypothalamic gray matter resulting in trigeminal activation coupled with parasympathetic activation. The pathophysiology remains controversial.

DIAGNOSIS

Per the *International Classification of Headache Disorders, 3rd edition,* the diagnosis of cluster headache requires all of the following:

- At least five attacks of severe or very severe unilateral orbital, supraorbital, and/or temporal pain lasting 15 to 180 minutes
- Frequency of every other day to eight per day; they may cluster seasonally or at a certain time in a patient's life
- Headache is accompanied by a sense of restlessness or agitation and/or at least one of the following (ipsilateral):
  1. Conjunctival injection and/or lacrimation
  2. Nasal congestion and/or rhinorrhea
  3. Eyelid edema
  4. Forehead and facial sweating
  5. Forehead and facial flushing
  6. Miosis and/or ptosis
  7. Sensation of fullness in the ear
  8. Restlessness or agitation

A diagnosis of episodic cluster headache requires the above criteria plus attacks that occur in bouts, also called cluster periods. These periods last 1 week to 1 yr and are separated by attack-free intervals lasting at least 1 month.

A diagnosis of chronic cluster headache requires meeting the criteria for cluster headache plus at least 1 yr of attacks without a pain-free interval of at least 1 month.

DIFFERENTIAL DIAGNOSIS

- Migraine
- Trigeminal neuralgia
- Primary stabbing headache
- Temporal arteritis
- Post-herpetic neuralgia
- Venous sinus thrombosis
- Carotid-cavernous fistula or other cavernous sinus lesions
- Other trigeminal autonomic cephalalgias
- Section II describes the differential diagnosis of headaches

WORKUP

Diagnosis is made clinically.

IMAGING STUDIES

- None, unless history or examination suggests focal neurologic deficit or headaches change in character or are of new onset.
- MRI of the brain along with vascular imaging may be necessary to exclude secondary headaches at the time of initial diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Avoidance of alcohol, histamine, nitroglycerin, and tobacco during clusters

ABORTIVE Rx

- Inhalation of 100% oxygen by face mask at a flow rate of 12 L/min or greater for 15 min aborts the attack in 60% to 80% of patients.
- Galcanezumab-gnlm is the first FDA-approved medication for episodic cluster headache in adults. First approved for migraine, this injectable medication is a humanized monoclonal antibody to calcitonin gene-related peptide (CGRP), blocking its binding to the CGRP receptor. It reduces the average number of cluster headaches per week from baseline compared to placebo.
- In approximately 75% of patients, subcutaneous or nasal triptans (e.g., sumatriptan, zolmitriptan) will result in freedom from pain within 20 minutes. Only injectable and nasal formulations achieve a response that is rapid enough to be efficacious.
- Cafergot, octreotide, intranasal lidocaine, or dihydroergotamine may abort an attack or prevent one if given just before a predictable episode. An attack typically resolves before oral analgesics can take effect, although indomethacin and other NSAIDs may be effective in prolonged attacks.

PROPHYLAXIS Rx

For patients with episodic cluster headache, prophylactic treatment should be started at the onset of the cluster period and tapered at its end. Patients with chronic cluster headache should be started on prophylactic treatment at increasing doses until good control is achieved. Preventative therapy should begin with verapamil. Alternative treatment options are also listed below.

- Verapamil: Start at 240 mg/day; increase up to 960 mg/day as tolerated. Dosing three times per day may be more effective than extended release. First-degree AV block may develop with escalating doses, so ECG should be checked.
- Topiramate: Up to 50 mg bid; can be used as add-on to verapamil.
- Lithium: 200 mg tid with frequent monitoring and adjustment to maintain therapeutic serum level of 0.4 to 1 mEq/L. Equally effective as verapamil, but with more side effects.
- Ergotamine tartrate: 3 to 4 mg/day during clusters.

- Melatonin: 10 mg per night. Evidence is weak and comes from scattered case reports.
- Prednisone: 60 mg PO daily for 1 wk followed by taper; headaches can return during taper.
- Greater and lesser occipital nerve blocks, with the use of local anesthetics including lidocaine and bupivacaine along with steroids like Depo-Medrol, dexamethasone, or triamcinolone, may be used to shorten the duration of the cluster period. Consensus guidelines from the American Headache Society have been published recently.
- There is emerging evidence for benefit of a sphenopalatine ganglion block that may be available at some centers for both treatment and prophylaxis of cluster attacks.

DISPOSITION

Headache-free periods tend to increase with increasing age.

REFERRAL

Refractory cluster headaches may require referral to a headache specialist.

PEARLS & CONSIDERATIONS

COMMENTS

- Cluster headaches are divided into episodic (attacks lasting up to 1 yr with more than 1 month pain-free periods) and chronic (>1 yr without remission). Episodic cluster headache is six times more common than the chronic form.
- Home oxygen therapy is reasonable for cluster headache sufferers.

BASIC INFORMATION

DEFINITION

Cocaine is an alkaloid derived from the coca plant *Erythroxylum coca,* native to South America, which contains approximately 0.5% to 1% cocaine. The drug produces physiologic and behavioral effects when administered orally, intranasally, intravenously, or by inhalation after smoking. Cocaine has potent pharmacologic effects on dopamine, norepinephrine, and serotonin neurons in the central nervous system (CNS) involving alteration and blockade of cellular membrane transport and prevention of reuptake. Cocaine's second action involves the blockage of voltage-gated sodium ion membrane channels, which is responsible for its anesthetic effect. Table 1 describes the pharmacokinetics of cocaine according to route of administration. The mechanism by which cocaine alters sympathetic tone is illustrated in Fig. 1.

SYNONYMS

Cocaine hydrochloride: Topical solution (FDA approved as a topical anesthetic)

Crack: This is produced when the hydrochloride molecule is removed by ether extraction, which frees the basic cocaine molecule or "free base." Heating does not destroy the free base; rather, it melts at 98° F and vaporizes at higher temperatures, allowing it to be smoked.

Freebase: Aqueous solution of cocaine hydrochloride converted to a more volatile base state by the addition of alkali, thereby extracting the cocaine base in a residue or precipitate.

Street names include Bernice, Blow, C, Carrie, Cecil, Charlie, Coke, Dust, Dynamite, Flake, Gin, Girl, Gold dust, Green gold, Jet, Powder, Star dust, Paradise, Pimp's drug, Snow, Stardust, White girl, Yay, Yayo

Liquid lady: Alcohol + cocaine

Speedball: Heroin + cocaine

Street measures: Git (2-200 mg), snort, line, dose, spoon (approximately 1 g)

ICD-10CM CODES

T40.5 Poisoning, cocaine
F14.20 Cocaine dependence, uncomplicated

EPIDEMIOLOGY & DEMOGRAPHICS

- The 2016 National Survey on Drug Use and Health published by the U.S. Department of Health and Human Services estimates that in 2016 1.9 million people aged 12 or older were current users of cocaine. This includes about 432,000 users of "crack" cocaine. The estimate is similar to those in most yrs between 2007 and 2015 but was lower than the estimates in 2002 to 2006.
- Table 2 summarizes characteristics of patients with cocaine-induced myocardial infarction.

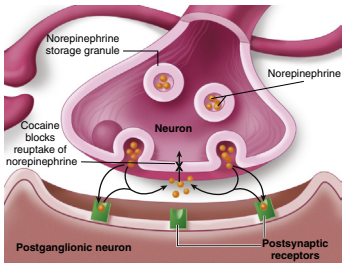

FIG. 1 Mechanism by which cocaine alters sympathetic tone. Cocaine blocks the reuptake of norepinephrine by the preganglionic neuron (X), thereby resulting in excess amounts of this neurotransmitter at postganglionic receptor sites. (From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

PHASE I:

- CNS: Euphoria, agitation, headache, vertigo, twitching, bruxism, unintentional tremor
- Nausea, vomiting, fever, hypertension, tachycardia

PHASE II:

- CNS: Lethargy, hyperreactive deep tendon reflexes, seizures (status epilepticus)
- Sympathetic overdrive: Tachycardia, hypertension, hyperthermia
- Incontinence

PHASE III:

- CNS: Flaccid paralysis, coma, fixed dilated pupils, loss of reflexes
- Pulmonary edema
- Cardiopulmonary arrest

Psychological dependence manifests with habituation, paranoia, and hallucinations (cocaine "bugs").

CNS: Cerebral ischemia and infarction, cerebral arterial spasm, cerebral vasculitis, cerebral vascular thrombosis, subarachnoid hemorrhage, intraparenchymal hemorrhage, seizures, cerebral atrophy, movement disorders, and hyperthermia

Cardiac: Acute myocardial ischemia and infarction (Fig. 2), arrhythmias (Table 3), and sudden death, dilated cardiomyopathy and myocarditis, infective endocarditis, aortic rupture, acceleration of coronary atherosclerosis

Pulmonary: Inhalation injuries (secondary to smoking crack cocaine): Cartilage and nasal septal perforation, oropharyngeal ulcers; immunologically mediated diseases: Hypersensitivity pneumonitis, bronchiolitis obliterans; pulmonary vascular lesions and hemorrhage, pulmonary infarction, pulmonary edema secondary to left ventricular failure, pneumomediastinum, and pneumothorax

Gastrointestinal: Gastroduodenal ulceration and perforation; intestinal infarction or perforation, colitis

Renal: Acute renal failure secondary to rhabdomyolysis and myoglobinuria; renal infarction; focal segmental glomerulosclerosis

Obstetric: Placental abruption, low infant weight, prematurity, microcephaly

Psychiatric: Anxiety, depression, paranoia, delirium, psychosis, suicide

Adulterants such as levamisole (an immunomodulator) and clenbuterol (a beta-adrenergic agonist) have been found mixed with cocaine. Levamisole can cause agranulocytosis, leukoencephalopathy, and cutaneous vasculitis leading to necrosis of the skin. Clenbuterol may cause tachycardia, hyperglycemia, and hypokalemia.

ETIOLOGY

Cocaine may be absorbed through different routes with varying degrees of speed:

- Nasal insufflation/snorting: 2.5 min
- Smoking: <30 sec
- Oral: 2 to 5 min
- Mucosal: <20 min
- Intravenous injection: <30 sec

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Methamphetamine ("speed") abuse

TABLE 1 Pharmacokinetics of Cocaine According to Route of Administration

Route of Administration	Onset of Action	Peak Effect	Duration of Action
Inhalation (smoking)	3-5 sec	1-3 min	5-15 min
Intravenous	10-60 sec	3-5 min	20-60 min
Intranasal or other mucosal	1-5 min	15-20 min	60-90 min

From Bonow RO et al: *Heart disease,* ed 9, Philadelphia, 2012, Saunders.

TABLE 2 Characteristics of Patients with Cocaine-Induced Myocardial Infarction

Dose of Cocaine

5-6 lines (150 mg) to as much as 2 g
Serum concentration, 0.01-1.02 mg/L

Frequency of Use

Reported in chronic, recreational, and first-time users

Route of Administration

Occurs with all routes of administration
75% of reported MIs occurred after intranasal use

Age

Mean, 34 (range, 17-71) yr
20% younger than 25 yr

Sex

80%-90% male

Timing

Often within minutes of cocaine use
Reported as late as 5-15 hr after use

From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.
MI, Myocardial infarction.

- Methylenedioxyamphetamine ("ecstasy") abuse
- Cathinone ("khat") abuse
- Lysergic acid diethylamide (LSD) abuse

WORKUP

Physical examination and laboratory evaluation

LABORATORY TESTS

- Toxicology screen (urine): Cocaine is metabolized within 2 hr by the liver to major metabolites, benzoylecgonine, and ecgonine methyl ester, which are excreted in the urine. Metabolites can be identified in urine within 5 min of IV use and up to 48 hr after oral ingestion

TABLE 3 Cardiac Dysrhythmias and Conduction Disturbances Reported with Cocaine Use

Sinus tachycardia
Sinus bradycardia
Supraventricular tachycardia
Bundle branch block
Complete heart block
Accelerated idioventricular rhythm
Ventricular tachycardia
Ventricular fibrillation
Asystole
Torsades de pointes
Brugada pattern (right bundle branch block with ST-segment elevation in leads V_1, V_2, and V_3)

From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.

- Blood: CBC, electrolytes, glucose, BUN, creatinine, calcium
- Arterial blood gas analysis
- ECG
- Serum creatine kinase and troponin concentration

Rx TREATMENT

- There is no specific antidote, and at present, no drug therapy is uniquely effective in treating cocaine abuse and dependence.
- Modifying cocaine's pharmacokinetic properties by sequestering or hydrolyzing it in serum and limiting its access to its sites of action may prove helpful by using a bacterial cocaine esterase, currently investigational.
- Adulterants (such as levamisole and clenbuterol, discussed earlier), contaminants, and other drugs may be admixed with street cocaine and should be kept in mind with patients presenting with unusual manifestations.
- Amantadine may provide effective treatment for cocaine-dependent patients with severe cocaine withdrawal symptoms, as well as the other dopamine agonist, bromocriptine (1.5 mg PO tid), which may alleviate some of the symptoms of craving associated with acute cocaine withdrawal.

ACUTE GENERAL Rx

- Acute cocaine toxicity requires following advanced poisoning treatment and life support.

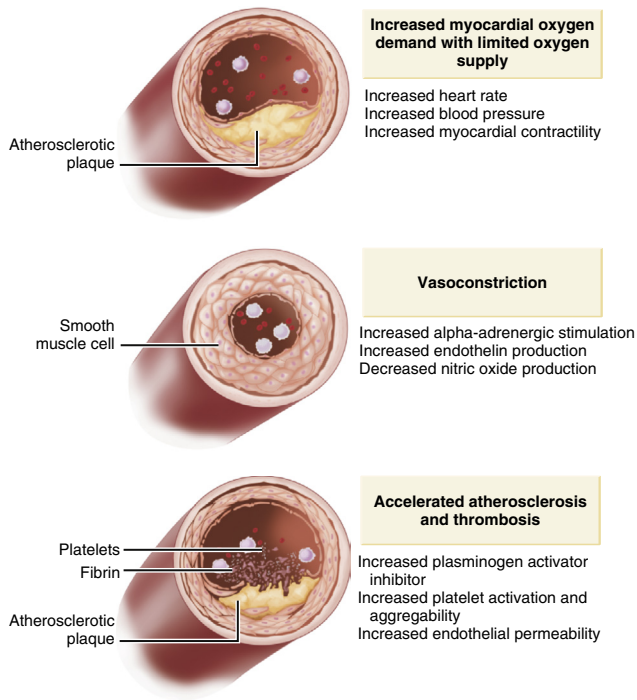

FIG. 2 Mechanisms by which cocaine may induce myocardial ischemia or infarction. Cocaine may induce myocardial ischemia or infarction by increasing the determinants of myocardial oxygen demand in the setting of limited oxygen supply (*top*), thereby causing intense coronary arterial vasoconstriction (*middle*) or inducing accelerated atherosclerosis and thrombosis (*bottom*). (From Mann DL et al: *Braunwald's heart disease*, ed 10, Philadelphia, 2015, Elsevier.)

- A suspected "body packer" should have an abdominal radiograph to detect the continued presence of cocaine-containing condoms in the intestinal tract.
  - If present, gentle catharsis with charcoal and mineral oil should be performed with ICU admission and monitoring.

SPECIFIC TREATMENT

INHALATION: Wash nasal passages

AGITATION:
- Check STAT glucose
- Diazepam 15 to 20 mg PO or 2 to 10 mg IM or IV for severe agitation

HYPERTHERMIA:
- Check rectal temperature, creatine kinase, electrolytes
- Monitor with continuous rectal probe; bring temperature down to 101° F within 30 to 45 min

RHABDOMYOLYSIS:
- Vigorous hydration with urine output at least 2 ml/kg
- Mannitol or bicarbonate for rhabdomyolysis resistant to hydration

SEIZURE MANAGEMENT (STATUS EPILEPTICUS):
- Diazepam 5 to 10 mg IV over 2 to 3 min; may be repeated every 10 to 15 min
- Lorazepam 2 to 3 mg IV over 2 to 3 min; may be repeated
- Phenytoin loading dose 15 to 18 mg/kg IV at a rate not to exceed 25 to 50 mg/min under cardiac monitoring
- Phenobarbital loading dose 10 to 15 mg/kg IV at a rate of 25 mg/min; an additional 5 mg/kg may be given in 30 to 45 min if seizures are not controlled
- For refractory seizures, consider:
  1. Pancuronium 0.1 mg/kg IV
  2. Halothane general anesthesia
  3. Both require EEG monitoring to determine brain seizure activity

HYPERTENSION: Cocaine-induced hypertension usually responds to benzodiazepines. If this fails:
- Consider arterial line for continuous blood pressure monitoring.
- The use of beta-blockers may exacerbate cocaine-induced vasoconstriction and may cause paradoxical hypertension, worsening patient outcomes.
- Phentolamine (unopposed adrenergic effects) or nitroglycerin may be required.
- If diastolic pressure >120 mm Hg: Hydralazine hydrochloride 25 mg IM or IV; may repeat q1h.
- If hypertension is uncontrolled or hypertensive encephalopathy is present: Sodium nitroprusside initially at 0.5 mg/kg/min not to exceed 10 mg/kg/min.

CHEST PAIN:
- Chest radiograph, ECG, cardiac enzymes.
- Benzodiazepines (diazepam 5 mg IV or lorazepam 1 mg IV every 5 minutes) for agitation until sedation is achieved.
- Acetylsalicylic acid and nitroglycerin for ischemic pain. (Aspirin is contraindicated if dissection is suspected.)

- Percutaneous transluminal coronary angioplasty possibly better than thrombolysis for cocaine-associated myocardial infarction.
- Phentolamine will reverse cocaine-induced vasoconstriction and may be administered 5 to 10 mg every 5 to 10 min.
- Calcium channel blockers (diltiazem 20 mg IV or verapamil 2.5 to 5 mg IV) are considered safe and may be used in patients with ongoing ischemic pain.
- The use of beta-adrenergic blockers is not generally recommended for reasons highlighted earlier.
- If beta-blockers are to be used, this should be preceded by administration of phentolamine to prevent unopposed alpha-adrenergic stimulation. Many authors recommend not using beta-blockers until the cocaine has been systemically eliminated.

VENTRICULAR ARRHYTHMIAS (CONSIDERATIONS):

- The Advanced Cardiac Life Support (ACLS) protocol should be followed.
- Antiarrhythmic agents should be used with caution during the early period after cocaine exposure as a result of their proarrhythmic and proconvulsant effects.
- Termination of ventricular arrhythmias may be resistant to lidocaine and even cardioversion.
- In a cardiac arrest situation secondary to cocaine toxicity, vasopressin offers a theoretical advantage over epinephrine as it increases coronary blood flow and myocardial oxygen availability. In the 2015 ACLS update, however, vasopressin was removed from the treatment algorithm, so it may not be readily available.

DISPOSITION

Although many patients who use cocaine may not require treatment because of the short half-life of the drug, others may require specific treatment for possible cocaine-related complications. Box 1 summarizes complications associated with cocaine use.

REFERRAL

Consider psychotherapy or behavioral therapy once stable. There is some evidence that topiramate 300 mg orally daily added to cognitive behavioral therapy may be beneficial in patients with severe withdrawal symptoms.

BOX 1 Complications Associated with Cocaine Use

Cardiovascular
Myocardial ischemia, infarction
Arrhythmias
Aortic dissection, rupture
Hypertension
Atherosclerosis
Cardiomyopathy
Vasculitis

Central Nervous System
Seizures
Cerebral infarction
Transient ischemic attack
Intracranial hemorrhage (intraparenchymal, intraventricular, subarachnoid)
Cerebral vasculitis
Cognitive dysfunction

Pulmonary
Bronchospasm
Barotrauma
Noncardiogenic edema
Pulmonary hypertension

Renal
Renal infarction
Renal failure
Scleroderma renal crisis

Gastrointestinal
Mesenteric ischemia, infarction
Gastrointestinal tract perforations

Metabolic
Hyperthermia
Rhabdomyolysis
Weight loss
Multiple organ failure

Other
Deep venous thrombosis
Skin ischemia
Dystonic reactions

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 4, Philadelphia, 2014, Elsevier.

PEARLS & CONSIDERATIONS

- Cocaine-induced vasoconstriction may be exacerbated by the use of selective and nonselective beta-adrenergic blocking agents.
- The use of lidocaine in treating ventricular arrhythmias may precipitate seizures and further arrhythmias.
- Clinical trials with the SSRI sertraline 200 mg/day have shown that it may help prevent relapse in individuals with some depression symptoms.

Coccidioidomycosis PTG

BASIC INFORMATION

DEFINITION

Coccidioidomycosis is an infectious disease caused by inhaling the spores of the dimorphic fungus *Coccidioides.* There are two known species: *C. immitis* from California isolates and *C. posadasii* from other endemic areas (Texas, Arizona, New Mexico, Mexico, and Central and South America). Clinical syndromes range from subclinical pulmonary disease to pneumonia and disseminated disease mostly in immunocompromised hosts. Most cases occur in the southwest part of the U.S.

SYNONYMS

San Joaquin Valley fever
Valley fever

ICD-10CM CODES

B38.1	Chronic pulmonary coccidioidomycosis
B38.2	Pulmonary coccidioidomycosis, unspecified
B38.3	Cutaneous coccidioidomycosis
B38.4	Coccidioidomycosis meningitis
B38.9	Acute pulmonary coccidioidomycosis
B38.89	Other forms of coccidioidomycosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Estimated annual infection rate is 150,000 persons, predominantly in the southwest U.S., and appears to be rising because of increased population and construction in the area. In endemic areas, the annual risk of infection is 3%.

PREVALENCE: 28.65 cases per 1 million population in the southwest U.S. based on patients requiring hospital admission.

PREDOMINANT SEX:

- Males, between the ages of 25 and 55 yr
- Clinical disease more severe in older children and adults

PEAK INCIDENCE: Seasonal in endemic areas with the highest risk being in the dry season after a rainy season as the mold lies a few inches below desert surface in soil and can become aerosolized.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Infection is usually acquired by inhalation of aerosolized arthroconidia.
- The clinical manifestations vary widely according to the host, severity of the illness, and location of dissemination.
- Asymptomatic infections or illness consistent with a nonspecific upper respiratory tract infection in at least 60%.
- Symptoms of primary infection—cough, malaise, fever, chills, night sweats, anorexia, weakness, and arthralgias (desert rheumatism)—in remaining 40% within 3 wk of exposure.
- Erythema nodosum and erythema multiforme more common in women.
- Scattered rales and dullness on percussion.
- Spontaneous improvement within 2 wk of illness, with complete recovery usual.
- Pulmonary nodules and cavities in <10% of those patients with primary infection; half of these patients are asymptomatic.
- In a small portion of these patients: A progressive pneumonitis, often with a fatal outcome.
- Immunocompromised or diabetic patients may progress to chronic pulmonary disease.
- Over time, granulomas rupture, leading to new cavity formation and continued fibrosis, often accompanied by hemoptysis.
- Disseminated or extrapulmonary disease in approximately 0.5% of acutely infected patients.
  1. Early signs of probable dissemination: Fever, malaise, hilar adenopathy, and elevated erythrocyte sedimentation rate persisting in the setting of primary infection.
  2. Most organs are susceptible to dissemination, with the heart and GI tract generally spared.
- Musculoskeletal involvement: Bone lesions often unifocal, ribs, long bones, and vertebral lesions are common.
  1. Joint lesions predominantly unifocal, most commonly involving the ankle and knee, and often accompanying adjacent sites of osteomyelitis.
- Meningeal involvement: Headache, fever, weakness, confusion, lethargy, cranial nerve defects, seizures; meningeal signs often minimal or absent.
- Cutaneous involvement (Fig. E1): Variable lesions—pustules, papules, plaques, nodules, ulcers, abscesses, or verrucous proliferative lesions.
  1. Dissemination and fatal outcomes most common in men, pregnant women, neonates, immunocompromised hosts, and individuals of dark-skinned races, especially those of African, Filipino, Mexican, and Native American ancestry.

ETIOLOGY

- In the U.S., endemic areas coincide with the Lower Sonoran Life Zone, with semiarid climate, sparse flora, and alkaline soil in Arizona, California, New Mexico, and Texas.
- Fungus exists in the mycelial phase in soil, having barrel-shaped hyphae (arthroconidia). Arthrospores are aerosolized and deposit in the alveoli, and then fungus converts to thick-walled spherules.
- Internal spherical spores (endospores) are released through spherule rupture and mature into new spherules (parasitic cycle).
- Fungus incites a granulomatous reaction in host tissue, usually with caseation necrosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute pulmonary coccidioidomycoses:
  1. Community-acquired pneumonias caused by *Mycoplasma* and *Chlamydia* spp.
  2. Granulomatous diseases, such as *Mycobacterium tuberculosis* and sarcoidosis
  3. Other fungal diseases, such as *Blastomyces dermatitidis* and *Histoplasma capsulatum*
- Coccidioidomas: True neoplasms

WORKUP

Coccidioidomycosis is definitively diagnosed by isolation of the organism in culture. Suspected in patients with a history of residence or travel in an endemic area, especially during periods favorable to spore dispersion (e.g., dust storms and drought followed by heavy rains)

LABORATORY TESTS

- Definitive diagnosis based on demonstration of the organism by culture from body fluids or tissues. It should be noted that culture can take days to several weeks to grow.

FIG. E1 Cutaneous coccidioidomycosis. Multiple verrucous papules and plaques in a patient with cutaneous coccidioidomycosis disseminated from a primary pulmonary infection. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.)

1. Greatest yield with pus, sputum, synovial fluid, and soft tissue aspirations, varying with the degree of dissemination.
2. Possible positive cultures of blood, gastric aspirate, pleural effusion, peritoneal fluid, and cerebrospinal fluid (CSF) but less frequently obtained.
3. Lab personnel are at risk of infection by inhalation on opening culture plates so lab should be notified the disease is suspected, but it is not contagious from person to person.

- Serologic evaluations: Useful for diagnosing and monitoring the course of therapy. They are the preferred method for diagnosing primary coccidioidal infections.
  1. Enzyme-linked immunoassays measure immunoglobulin M (IgM) and IgG antibodies and are used as a screening test. If positive, then an immunodiffusion test is used that also measures IgM and IgG. Enzyme immunoassay tests have a high sensitivity but are less specific than the immunodiffusion test.
  2. Elevated serum complement-fixing antibody (CFA) titers ≥1:32 strongly correlated with disseminated disease, and their detection in the CSF is an especially important aid in diagnosing coccidioidal meningitis.
  3. Coccidioidal serum and urine assays are available but insensitive. They can be useful in diagnosing disease in severely immunocompromised persons (e.g., persons with AIDS) whose serologic tests are negative and in those with extensive disease.
  4. Coccidioidal antigen levels in CSF appear to be more sensitive than the antibody tests in CSF (93% vs. 85%) and much better than CSF culture.
- CBC to reveal eosinophilia, especially with erythema nodosum.
- Routine chemistries: Usually normal but may reveal hyponatremia.
- Elevated serum levels of IgE; associated with progressive disease.
- CSF cell counts and chemistry: Pleocytosis with mononuclear cell predominance associated with hypoglycorrhachia and elevated protein level.

IMAGING STUDIES

Chest radiography:

- Reveals unilateral infiltrates, hilar adenopathy, or pleural effusion in primary infection
- Shows areas of fibrosis containing usually solitary, thin-walled cavities that persist as residua of primary infection
- Possible coccidioidoma, a coinlike lesion representing a healed area of previous pneumonitis

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive care in mild symptomatic disease
- In patients with extrapulmonary manifestations involving draining skin, joint, and soft tissue infection: Local wound care to avoid possible bacterial superinfection

ACUTE GENERAL Rx

- In general, drug therapy is not required for patients with asymptomatic pulmonary disease and most patients with mild symptomatic primary infection.
- Chemotherapy is indicated under the following circumstances:
  1. Severe symptomatic primary infection.
  2. High serum CFA titers.
  3. Persistent symptoms >6 wk.
  4. Prostration.
  5. Progressive pulmonary involvement.
  6. Pregnancy.
  7. Infancy.
  8. Debilitation.
  9. Concurrent illness (e.g., diabetes, asthma, COPD, malignancy).
  10. Acquired or induced immunosuppression.
  11. Racial group with known predisposition for disseminated disease.
- Fluconazole:
  1. Most commonly, oral therapy with 400 mg/day up to 1.2 g/day appears to be the drug of choice for meningeal and deep-seated mycotic infections.
  2. In patients with AIDS, fluconazole may be considered the drug of choice for initial and maintenance therapy.
  3. All patients with coccidioidal meningitis should continue azole therapy indefinitely.
- Itraconazole:
  1. 400 to 600 mg/day achieves 90% response rate in bone, joint, soft tissue, lymphatic, and genitourinary infections.
  2. Itraconazole may be more efficacious than fluconazole in the treatment of skeletal (bone) infections but has more drug-drug interactions than fluconazole and must be taken with fatty food and an acidic beverage to increase absorption.
- Alternative regimens include posaconazole, a triazole agent that can be used as delayed release tablets or IV vs. suspension, or voriconazole: 6 mg/kg PO q 12 h × 2, then 4 mg/kg PO bid for patients weighing more than 40 kg.
- For pulmonary infections, treatment with either fluconazole or itraconazole, given for 6 to 12 wk, appears to be equal in efficacy.
- Treatment of coccidioidomycosis complicated by meningitis:
  1. Subacute or chronic meningitis presenting with headache, cranial nerve palsies, or focal neurological deficits.
  2. CSF findings include high-protein, lymphocytic pleocytosis and low glucose, and a CSF coccidioidal antigen may be more sensitive than antibody tests or CSF culture to detect meningeal involvement.
  3. Treatment can be with fluconazole: 400 to 1200 mg PO once a day; itraconazole: 400 to 800 mg PO divided two to four times daily; or voriconazole: 6 mg/kg PO/IV q12h × 24 h, then 4 mg/kg PO q12h.
  4. Alternative regimens with amphotericin B: For refractory cases can use intrathecal amphotericin B: 0.1 to 1.5 mg/dose, daily to weekly, or can use liposomal amphotericin B: 3 to 5 mg/kg IV daily.
  5. Patients who respond to azole therapy should continue for life, as relapses are common and potentially life-threatening.
- For osteomyelitis, soft tissue closed-space infections, and pulmonary fibrocavitary disease: Surgical debridement, drainage, or resection, respectively, in addition to oral azole therapy or parenteral administration of amphotericin B.

TABLE E1 Risk Factors for Poor Outcome in Young Patients with Active Coccidioidomycosis

Primary Infections
Severe, prolonged (≥6 wk), or progressive infection
Risk Factors for Extrapulmonary Dissemination
Primary or acquired cellular immune dysfunction (including patients receiving tumor necrosis factor inhibitors)
Neonates, infants, older adults
Male sex (adult)
Filipino, African, Native American, or Latin American ethnicity
Late-stage pregnancy and early postpartum period
Standardized complement fixation antibody titer >1:16 or increasing titer with persisting symptoms
Blood group B
HLA class II allele-DRB1*1301

HLA, Human leukocyte antigen.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.

CHRONIC Rx

For chronically immunocompromised patients, lifelong therapy with oral azoles or amphotericin B. Azoles should be avoided in women during the first trimester of pregnancy because of their teratogenic potential.

DISPOSITION

- Prognosis for primary symptomatic infection is good.
- Immunocompromised patients are most likely to have disseminated disease and higher morbidity and mortality.
- Risk factors for poor outcome in patients with active coccidioidomycosis are described in Table E1.

REFERRAL

- To surgeon for the evaluation of chronic hemoptysis, enlarging cavitary lesions despite chemotherapy and intrapleural rupture, osteomyelitis, and other synovial or soft tissue closed-space infections
- For neurosurgical consultation in patients with meningeal disease to establish the delivery route of intrathecal drug therapy

PEARLS & CONSIDERATIONS

COMMENTS

- Although coccidioidomycosis is a great imitator, a diagnosis will become apparent if a high degree of suspicion is maintained and appropriate testing (serologic testing, cultures, and histology) is performed.
- Infected body fluids contained within a closed moist environment (e.g., sputum in a specimen cup) provide the opportunity for the fungus to revert to its hyphal form whereby spores may be made airborne on opening of the container. This is a biohazard for laboratory personnel. Another example on a hospital floor occurred when purulent drainage in a closed cast, allowed conversion of fungus to the saprophytic phase, and then was responsible for acute disease when the cast was sawed opened and the spores were unintentionally made airborne.
- Patients with a remote history of exposure, especially if immunosuppressed by medication or disease, may reactivate primary disease and suffer rapid dissemination.
- Although cardiac disease is rare, constrictive pericarditis in the setting of disseminated coccidioidomycosis has been documented and is potentially fatal.
- Organ transplant recipients may develop disease if the transplant donor has unrecognized active coccidioidomycosis at the time of death.

BASIC INFORMATION

DEFINITION

Cogan syndrome is a very rare autoimmune inner ear disorder that is temporally associated with an inflammatory eye disease, usually interstitial keratitis, and is thought to be mediated by a hypersensitivity response to infectious agents associated with vasculitis.

ICD-10CM CODE
H16.3 Interstitial and deep keratitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: No population studies are available for incidence calculation. Approximately 250 cases have been described in the literature to date.
PREVALENCE: No population studies are available for prevalence analysis. The classic form of Cogan syndrome tends to affect Caucasian individuals.
PREDOMINANT SEX: No gender preference. Affects men and women equally in case reports.
PREDOMINANT AGE: Median age of onset is 22 yr, with range 5 to 63 yr. Cases reported in children and older adults.
RISK FACTORS: Cogan syndrome may have increased prevalence in patients with inflammatory bowel disease. In many case reports, infectious processes have been implicated, such as previous upper respiratory tract infections that led to cross-reactive autoantibodies. Smoking may be a trigger.
GENETICS: Unknown.

TABLE E1 Systemic Manifestations of Cogan Syndrome

Manifestations	Cases (%)
Fever	25
Fatigue	20
Arthralgia/myalgia	15
Arthritis	15
Weight loss	15
Abdominal pain	10
Gastrointestinal bleeding	10

PHYSICAL FINDINGS & CLINICAL PRESENTATION

See Table E1 for systemic manifestations of Cogan syndrome.
Clinical hallmarks:

- Cogan syndrome is characterized by an acute, subacute, or recurrent onset of inner ear loss of function resembling Meniere disease (tinnitus, vertigo, and gradual hearing loss). The resultant hearing loss typically is sensorineural, bilateral, and progressive. This is temporally related to the onset of keratitis manifested as pain, redness, and blurry vision in the affected eye. Systemic vasculitis features are marked by large-vessel vasculitis and can occur in up to 10% of patients. Medium-vessel vasculitis resembling polyarteritis nodosa to small-vessel vasculitis manifestations are possible.
- Constitutional: Fever, headache, weight loss, malaise.
- Ocular: Redness, pain, photophobia, and blurred vision as a result of interstitial keratitis (72% to 100%). Scleritis or episcleritis (23%). The gap between involvement of audiovestibular and ocular symptoms is usually 1 to 6 months and not more than 2 yr.
- Hearing/vestibular: Hearing loss progressing to deafness, usually bilateral (100%), vertigo (90%), and tinnitus (80%). Imbalance may be associated with nausea and vomiting.
- Cardiovascular: Aortitis, aortic aneurysm, aortic insufficiency.
- Musculoskeletal: Arthralgia, arthritis, myalgia.
- Neurologic: Hemiparesis and hemiplegia.
- Gastrointestinal: Abdominal pain (13% to 16%), diarrhea, melena.
- Renal: Hematuria (7%), glomerulonephritis (3%).
- Dermatologic: Cutaneous nodules, rash.

ETIOLOGY

The exact etiology of Cogan syndrome is unknown. Evidence of an autoimmune mechanism includes binding of autoantibodies from patients with Cogan syndrome to the cochlea of mice in passive transfer studies. Autopsy specimens show nonspecific lymphocytic and plasma cell infiltration. Infection is thought to be a trigger. Some HLA loci, including HLA-B17, HLA-A9, HLA-Bw35, and HLA-Cw4, correlate with the disorder.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious diseases:
  1. Syphilis
  2. Tuberculosis, Lyme disease, chlamydia, leprosy, brucellosis, mumps, EBV, herpes zoster, and herpes simplex; rubeola should be considered in the differential for interstitial keratitis
- Rheumatology:
  1. ANCA-associated vasculitis: Granulomatosis with polyangiitis (formerly Wegener granulomatosis)
  2. Takayasu arteritis
  3. Giant cell arteritis
  4. Rheumatoid arthritis with vasculitis
  5. Polyarteritis nodosa
  6. Behçet disease
  7. Sarcoidosis
- Neurology:
  1. Susac syndrome
  2. Occlusive nonvasculitis vasculopathy
- Neoplastic:
  1. Lymphoma (CNS)
- Miscellaneous:
  1. Vogt-Koyanagi-Harada syndrome
  2. Inflammatory bowel disease (Crohn disease)

LABORATORY TESTS

- Diagnosis of Cogan syndrome is usually made on clinical evidence.
- Inflammatory markers are often elevated, including the erythrocyte sedimentation rate (ESR) and C-reactive protein.
- Complete blood cell count with differential; may show leukocytosis.
- ANCA serology test to evaluate for ANCA-associated vasculitis.
- Serologic test result should be negative for syphilis.
- Anti-Hsp 70 antibodies have been suggested as possible markers of typical Cogan syndrome (also found in other forms of autoimmune sensorineural hearing loss).

IMAGING STUDIES

- Initial tone audiogram shows a hearing loss, especially at high frequencies.
- MRI with gadolinium of the brain to rule out non–inner-ear causes for acute or subacute hearing loss and vestibular dysfunction. Brain MRI can range from normal to gadolinium enhancement of the vestibular-cochlear structures.
- MRA of the aorta and its proximal branches may be used to assess for vascular inflammation that may support the diagnosis of large-vessel vasculitis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Cochlear implant

ACUTE GENERAL Rx

- Treatment guidelines are based on grade C (fair evidence from ancillary studies) recommendations. Table E2 summarizes treatment modalities for Cogan syndrome.
- Early treatment is critical for a favorable prognosis.
- Eye symptoms: Unlike audiovestibular symptoms, ocular manifestations typically respond to topical corticosteroids. Mydriatics may be considered.
- Vestibuloauditory symptoms: Divided doses of oral prednisone 1 to 2 mg/kg/day.
- Vasculitis symptoms: Divided doses of oral prednisone 1 to 2 mg/kg/day. Oral or IV cyclophosphamide should be considered for life-threatening features.

TABLE E2 Treatment of Cogan Syndrome

Disease Manifestations	Recommended Treatment
Ocular	
Interstitial keratitis	Topical ocular corticosteroids and mydriatics (atropine)
Iridocyclitis	Low-potency topical corticosteroids such as 1% prednisolone acetate (3-7 days)
Anterior uveitis	Systemic corticosteroids (only in the case of failure of topical therapy)
Suspected chlamydial infection	Treatment with a tetracycline antibiotic (doxycycline) (200 mg/day for 2-3 wk)
Posterior-segment ocular inflammation	Systemic steroids DMARDs as steroid-sparing agents
Audiovestibular	
Acute vestibular symptoms	Diuretics, antihistamines, bed rest
Chronic vestibular symptoms	Vestibular exercises
Hearing loss	
Hearing loss	Corticosteroids: Prednisolone 1 mg/kg daily (up to 60 mg) for 2 wk and then taper; duration of initial treatment, 4-6 mo Consider immunosuppressant therapy with steroid-sparing agents
Severe hearing loss unresponsive to medical treatment	Cochlear implant
Systemic Vasculitis	
Cogan syndrome with large-vessel vasculitis	Corticosteroids and cyclosporine or cyclophosphamide
Cogan syndrome with medium-vessel vasculitis	Corticosteroids and cyclophosphamide as per treatment of polyarteritis nodosa

DMARD, Disease-modifying antirheumatic drug.
From Hochberg MC et al: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

CHRONIC Rx

- Methotrexate, cyclophosphamide, or azathioprine may be considered as steroid-sparing agents.
- Treatment options such as TNF-alpha inhibitors (infliximab and etanercept), plasmapheresis, rituximab, tocilizumab, cyclosporine, and mycophenolate mofetil have been reported in the literature.

DISPOSITION

- Ocular outcomes are good.
- Hearing loss may occur in up to 50% of cases.

REFERRAL

- Ophthalmology for complete ocular examination, including slit-lamp examination.
- Rheumatology/immunology for all patients with suspected disease.
- Audiology for complete hearing assessment.
- Otolaryngology for confirmation of sensorineural hearing loss.

BASIC INFORMATION

DEFINITION

Colorado tick fever is an acute, self-limited febrile illness caused by infection with a Coltivirus.

ICD-10CM CODE
A93.2 Colorado tick fever

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence: Approximately 330 cases reported per yr in the U.S.
- Demographics: Children and adults of both genders.
- Geography: Rocky Mountains at elevations of 4000 to 10,000 feet. Sporadic cases have been reported from areas of California outside the range of *Dermacentor andersoni.*
- Colorado has the highest incidence Fig. E1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation: 3 to 4 days is usual but can be up to 14 days.
- First symptoms: Fever, chills, severe headache, severe myalgias, and hyperesthetic skin.
- Initial signs and symptoms:
  1. Tick bite (reported by more than 90% of parents)
  2. Fever and chills
  3. Headache
  4. Myalgias
  5. Weakness
  6. Prostration and indifference
  7. Injected conjunctivae
  8. Erythematous pharyngitis
  9. Lymphadenopathy and hepatosplenomegaly may be found in some patients
  10. Maculopapular or petechial rash 5.6%-12% of cases
- These first symptoms last for 1 wk or less, but 50% of patients have a febrile relapse 2 to 3 days after an initial remission. Weakness and fatigue may persist for several months after the acute phase(s). This chronic phase is more likely in older patients.
- In children, 5% to 10% of cases are complicated by aseptic meningitis. In adults, rare complications include pneumonia, hepatitis, myocarditis, and epididymo-orchitis. Vertically transmitted fetal infection is possible.

ETIOLOGY

- Infectious agent: Coltiviruses; seven species, including three in the U.S.
- Vector: Wood tick, *D. andersoni* (Fig. E2).
- Pathogenesis: Human transmission occurs by tick bite. Tick season spans from March to September. The virus infects marrow erythrocytic precursors, explaining the protracted disease course because viremia lasts for the life span of the infected red blood cell. Fig. E3 illustrates the ecology of Colorado tick fever virus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rocky Mountain spotted fever
- Influenza
- Leptospirosis
- Infectious mononucleosis
- CMV infection
- Pneumonia
- Hepatitis
- Meningitis
- Endocarditis
- Scarlet fever
- Measles
- Rubella
- Typhus
- Lyme disease
- Immune thrombocytopenic purpura (ITP)
- Thrombotic thrombocytopenic purpura (TTP)
- Kawasaki disease
- Toxic shock syndrome
- Vasculitis

WORKUP

Consider Colorado tick fever in the presence of the above symptoms associated with travel to an endemic area coupled with a history of tick exposure.

LABORATORY TESTS

- Complete blood count:
  1. Leukopenia
  2. Atypical lymphocytes
  3. Moderate thrombocytopenia
- Virus identification in red blood cells by indirect immunofluorescence
- Serology with enzyme-linked immunosorbent assay, neutralization, or complement fixation

TREATMENT

- No specific therapy, although Coltiviruses are sensitive to ribavirin
- Bed rest, fluids, acetaminophen
- Avoid aspirin because of thrombocytopenia
- Prevention: Tick avoidance measures

BASIC INFORMATION

DEFINITION

Colorectal cancer (CRC) is a neoplasm arising from the luminal surface of the large bowel; locations include descending colon (40% to 42%), rectosigmoid and rectum (30% to 33%), cecum and ascending colon (25% to 30%), and transverse colon (10% to 13%).

ICD-10CM CODES

C18	Malignant neoplasm of colon
C18.2	Malignant neoplasm of colon, ascending colon
C18.4	Malignant neoplasm of colon, transverse colon
C18.6	Malignant neoplasm of colon, descending colon
C18.7	Malignant neoplasm of colon, sigmoid colon
C19	Malignant neoplasm of rectosigmoid junction

EPIDEMIOLOGY & DEMOGRAPHICS

- Worldwide, CRC accounts for about 1.4 million new cases and 700,000 deaths annually. The highest incidence is in North America, Australasia, Europe, and South Korea
- CRC is the fourth most common cancer and the second leading cause of cancer deaths in the U.S. (145,600 new cases and 51,020 deaths for 2019). Distant metastatic disease is present in 18% to 22% of patients at time of diagnosis
- The peak incidence is in the seventh decade of life. The lifetime risk for development of CRC is 1 in 17, with 90% of cases occurring after age 50 yr
- Risk factors (Table 1):
  1. Hereditary polyposis syndromes
  2. Familial polyposis (high risk)
  3. Gardner syndrome (high risk)
  4. Turcot syndrome (high risk)
  5. Peutz-Jeghers syndrome (low to moderate risk)
  6. Inflammatory bowel disease (IBD), both ulcerative colitis and Crohn disease
  7. Family history of "cancer family syndrome"
  8. Heredofamilial breast cancer and colon carcinoma
  9. Pelvic irradiation history
  10. First-degree relatives with colorectal carcinoma
  11. Age >50 yr
  12. Dietary factors (diet high in fat or red meat, alcohol use, low vegetable intake)
  13. Hereditary nonpolyposis colon cancer (HNPCC): Autosomal dominant disorder characterized by early age of onset (mean age, 44 yr) and right-sided or proximal colon cancers, synchronous and metachronous colon cancers, mucinous and poorly differentiated colon cancers; accounts for 1% to 5% of all cases of CRC; Criteria for diagnosis of HNPCC are summarized in Table 2
  14. Previous endometrial or ovarian cancer, particularly when diagnosed at an early age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination may be completely unremarkable.
- Digital rectal examination can detect approximately 50% of rectal cancers.
- Palpable abdominal masses may indicate metastasis or complications of colorectal carcinoma (abscess, intussusception, volvulus).
- Abdominal distention and tenderness are suggestive of colonic obstruction.
- Hepatomegaly is indicative of hepatic metastasis.

ETIOLOGY

CRC can arise through either of two mutational pathways: Microsatellite instability or chromosomal instability. Germline genetic mutations are the basis of inherited colon cancer syndromes; an accumulation of somatic mutations in a cell is the basis of sporadic colon cancer. Fig. 1 illustrates the molecular carcinogenesis of colon cancer. Approximately 15% of CRC lack one or more mismatch repair enzymes (mismatch repair deficient [dMMR]-CRC).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diverticular disease
- Strictures or adhesions
- Inflammatory bowel disease (IBD)
- Infectious or inflammatory lesions
- Arteriovenous malformations
- Metastatic carcinoma
- Extrinsic masses (cysts, abscesses)

WORKUP

The clinical presentation of colorectal malignancies may consist of nonspecific symptoms (weight loss, anorexia, malaise) or of specific symptoms related to mass effect or bleeding. It is useful to divide colon cancer symptoms into those usually associated with the right- or left-sided cancers because the clinical presentation can vary with the location.

- Right side of colon:
  1. Anemia (from chronic blood loss).
  2. Abdominal pain may be present, or the patient may be completely asymptomatic.
  3. Rectal bleeding is often missed because blood is mixed with feces.
  4. Obstruction and constipation are unusual because of large lumen and more liquid stools.
- Left side of colon:
  1. Change in bowel habits (constipation, diarrhea, tenesmus, pencil-thin stools).
  2. Rectal bleeding (bright red blood coating the surface of the stool).
  3. Intestinal obstruction is frequent because of small lumen.

CLASSIFICATION (TABLE 3) AND STAGING

AJCC 8th edition classification for CRC:

A. Confined to the mucosa-submucosa (stage I)
B. Invasion of muscularis propria (stage II)
C. Local node involvement (stage III)
D. Distant metastasis (stage IV)

TNM Classification:

Stage	TNM Classification
I	T_{1-2}, N_0, M_0
II_A	T_3, N_0, M_0
II_B	T_{4a}, N_0, M_0
II_C	T_{4b}, N_0, M_0
III_A	T_{1-2}, N_1, M_0; T_1, N_{2a}, M_0
III_B	T_{3-4a}, N_1, M_0 T_{2-3}, N_{2a}, M_0 T_{1-2}, N_{2b}, M_0
III_C	T_{4a}, N_{2a}, M_0 T_{3-4a}, N_{2b}, M_0 T_{4b}, N_{1-2}, M_0
IV_A	T(any), N(any), M_{1a}
IV_B	T(any), N(any), M_{1b}
IV_C	T(any), N(any), M_{1c}

LABORATORY TESTS

- Positive fecal occult blood test (FOBT): Many primary care physicians use single digital

TABLE 1 Recognized Risk Factors for Colorectal Cancer

Family History
- Colorectal cancer (CRC)
- Inherited syndromes (e.g., familial adenomatous polyposis [FAP])
- Racial and ethnic background (e.g., African American, Ashkenazi Jews)

Personal History
- Age
- Male sex
- Previous colonic polyps or CRC
- History of inflammatory bowel disease
- Diabetes mellitus

Lifestyle
- Obesity
- High consumption of alcohol
- Diet high in red meat and fat, low in fiber

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 Criteria for Diagnosis of Hereditary Nonpolyposis Colon Cancer (HNPCC)

Amsterdam Criteria[1]

- At least three relatives have colorectal cancer, and all of the following are present:
- One is a first-degree relative (parent, sibling, or child) of the other two
- At least two successive generations are involved
- At least one relative had colorectal cancer when he or she was younger than 50
- Familial adenomatous polyposis has been excluded

Revised Bethesda Guidelines[2]

(Indicates tumors to select for microsatellite instability testing)

- Colorectal cancer in a patient younger than 50 yr
- A second synchronous or metachronous colorectal cancer or cancer associated with HNPCC
- Presence of high-level microsatellite instability histologically in a patient younger than 60 yr
- One or more first-degree relatives with either colorectal cancer or HNPCC-associated tumor diagnosed at younger than 50 yr
- Colorectal cancer in two or more first- or second-degree relatives with HNPCC-related tumors at any age

Either all of the Amsterdam criteria or one of the Bethesda criteria is used to identify an individual at risk of HNPCC

- HNPCC-associated tumors include endometrial, gastric, ovarian, pancreatic, ureter, renal pelvis, biliary tract, small bowel, and brain

[1]Vasen HF, Watson P, Mecklin JP et al: New clinical criteria for hereditary nonpolyposis colorectal cancer (HNPCC, Lynch syndrome) proposed by the International Collaborative group on HNPCC. *Gastroenterology* 116:1453-1456, 1999.
[2]Umar A, Boland CR, Terdiman JP et al: Revised Bethesda Guidelines for hereditary nonpolyposis colorectal cancer (Lynch syndrome) and microsatellite instability. *J Natl Cancer Inst* 96:261-268, 2004.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

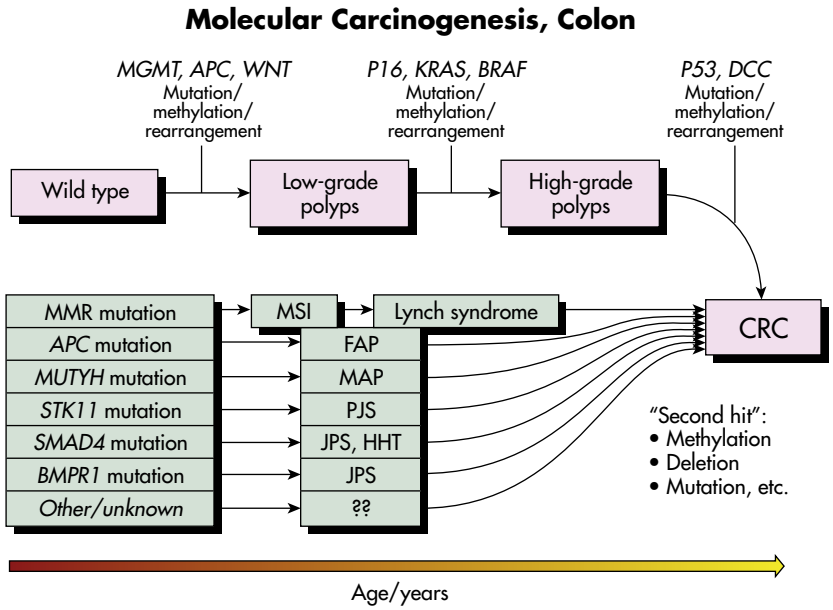

FIG. 1 Accumulation of molecular changes that precede colorectal carcinoma (CRC). Sporadic tumors are initiated by a serial accumulation of somatic mutations that may eventuate in CRC. The initiating event in these polyposes is the mutation present at birth. Second hits may include a variety of molecular changes, such as tumor suppressor gene promoter methylation, mutations, and copy number changes. Mismatch repair *(MMR)* includes *hMLH1, hMLH2, hMSH2, hPMS2,* and *EpCAMP* genes. *FAP,* Familial adenomatous polyposis; *HHT,* hereditary hemorrhagic telangiectasia; *JPS,* juvenile polyposis syndrome; *MAP, MUTYH*-associated polyposis; *MSI,* microsatellite instability; *PJS,* Peutz-Jeghers syndrome. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

FOBT as their primary screening test for CRC. Single FOBT has low specificity for detecting human hemoglobin, is a poor screening method for CRC (sensitivity, 4.9%), and is inappropriate as the only test because negative results do not decrease the odds of advanced neoplasia. The American College of Gastroenterology recommends the fecal immunochemical test (FIT), which measures intact human globin protein (as opposed to heme) in the stool and detects more advanced adenomas than FOBT.

- Fecal DNA testing is a newer screening method that detects colonic cells shed into the fecal stream that possess specific genetic or epigenetic changes. The technique has a reported sensitivity of 97% and a specificity of 90% for CRC stages I-III. In trials involving asymptomatic persons at average risk for colorectal cancer, multitarget stool DNA testing detects significantly more cancers than FIT but has more false-positive results. High cost and rate of false positives are the main obstacles inhibiting broader adoption of fecal DNA testing.
- Molecular markers including abnormal DNA from cancerous cells can be detected in stool. FIT combined with stool DNA test (FIT-DNA) has been approved by the FDA for colorectal screening. One study showed that one-time FIT-DNA had a higher sensitivity for detection of colorectal cancer than one-time FIT alone (92.3% vs. 73.8%), but specificity was lower (86.6% vs. 94.9%).[1]
- Circulating methylated SEPT9 DNA: Does not reliably detect precancerous neoplasia. Studies showing mortality benefit are lacking.
- Plasma carcinoembryonic antigen (CEA) level is not useful for screening because it can be increased in nonmalignant conditions (smoking, IBD, alcoholic liver disease). A normal CEA result does not exclude the diagnosis of CRC.

TABLE 3 World Health Organization Classification of Colorectal Carcinoma

- Adenocarcinoma
- Cribriform comedo-type adenocarcinoma
- Medullary carcinoma
- Micropapillary carcinoma
- Mucinous adenocarcinoma
- Serrated adenocarcinoma
- Signet ring cell carcinoma
- Adenosquamous carcinoma
- Spindle cell carcinoma
- Squamous cell carcinoma
- Undifferentiated carcinoma
- Neuroendocrine carcinoma (NEC):
  - Large NEC
  - Small NEC
- Mixed adenoneuroendocrine carcinoma

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

IMAGING STUDIES

- Colonoscopy with biopsy (primary assessment tool): The American College of Physicians (ACP) recommends that patients should be offered a colonoscopy beginning at age 50, and it should be repeated every 10 yr in average-risk patients. Screening is recommended in African Americans beginning at age 45 yr. Persons with only one first-degree relative with CRC or advanced adenomas diagnosed at 60 yr or older may be screened as at average risk. The U.S. Preventive Services Task Force guidelines state that screening should not be routinely recommended in persons older than 75 yr, and it should not be recommended at

[1]Inadomi JM: Screening for colorectal neoplasia, *N Engl J Med* 376:149-156, 2017.

TABLE 4 Colorectal Cancer (CRC) Screening and Surveillance Recommendations*

Indication	Recommendations
Average risk	Beginning at age 50 yr: Colonoscopy every 10 yr; Computed tomographic colonography every 5 yr; Flexible sigmoidoscopy every 5 yr; Double-contrast barium enema every 5 yr; Stool blood testing annually or stool; DNA testing acceptable but not preferred
One or two first-degree relatives with CRC at any age or adenoma at age <60 yr	Colonoscopy every 5 yr beginning at age 40 yr, or 10 yr younger than earliest diagnosis, whichever comes first
Hereditary nonpolyposis CRC	Genetic counseling and screening† Colonoscopy every 1 to 2 yr beginning at age 25 yr and then yearly after age 40 yr‡
Familial adenomatous polyposis and variants	Genetic counseling and testing† Flexible sigmoidoscopy yearly beginning at puberty‡
Personal history of CRC	Colonoscopy within 1 yr of curative resection; repeat at 3 yr and then every 5 yr if normal
Personal history of colorectal adenoma	Colonoscopy every 3 to 5 yr after removal of all index polyps
Inflammatory bowel disease	Colonoscopy every 1 to 2 yr beginning after 8 yr of pancolitis or after 15 yr if only left-sided disease

*Recommendations proposed by the American Cancer Society and U.S. Multi-Society Task Force on Colorectal Cancer; recommendations for average-risk patients also endorsed by the American College of Radiology.
†Whenever possible, affected relatives should be tested first because of potential false-negative results.
‡Screening recommendation for individuals with positive or indeterminate tests as well as for those who refuse genetic testing.
From Andreoli TE et al: *Andreoli and Carpenter's Cecil essentials of medicine,* ed 8, Philadelphia, 2010, Saunders.

all in persons older than 85 yr. If persons between the ages of 75 and 85 yr have never undergone screening, the decision about screening should be individualized according to health status. The ACP recommends that clinicians stop screening for colorectal cancer in adults over age 75 yr or in adults with a life expectancy of <10 yr. Table 4 describes CRC screening and surveillance recommendations.

- Computed tomography colonoscopy (CTC) virtual colonoscopy (VC) uses helical (spiral) CT scanning to generate a two- or three-dimensional virtual colorectal image (Fig. E2). CTC does not require sedation, but, like optical colonoscopy, it requires some bowel preparation (either bowel cathartics or ingestion of iodinated contrast medium with meals during the 48 hr before CT) and air insufflation. It also involves substantial exposure to radiation. In addition, patients with lesions detected by VC will require traditional colonoscopy. Compared with colonoscopy, CTC sensitivity for detection of polyps >10 mm ranges from 70% to 96%, and specificity ranges from 72% to 96%. CTC has replaced double-contrast barium enema as the radiographic screening alternative when patients decline colonoscopy.
- Capsule endoscopy allows visualization of the colonic mucosa but is not recommended as a screening procedure because its sensitivity for detecting colonic lesions is low compared with colonoscopy.
- CT scanning of the abdomen (Fig. E3), pelvis, and chest assists in preoperative staging.
- PET scanning (Fig. E4) can display functional information and is accurate in the detection of CRC and its distant metastases. Colonography composed of a combined modality of PET and CT is a newer diagnostic modality that can provide whole-body tumor staging in a single session.

Rx TREATMENT

GENERAL Rx

- Surgical resection is the definitive and curative upfront treatment for stages I-III colon cancers. Selected patients (high-risk stage II, all stage III) are recommended to receive adjuvant chemotherapy. Microsatellite instability can be used alongside clinicopathologic factors in stage II and III colorectal cancer to guide therapy (Fig. 5).
- The standard chemotherapy regimen for adjuvant therapy of resected CRC is the combination of oxaliplatin with a fluoropyrimidine (5-fluorouracil or capecitabine) for a period of 3 to 6 mo. Older patients and patients with significant comorbidities have more toxicity with combination chemotherapy; treatment with single-agent fluoropyrimidine therapy only is recommended.
- Neoadjuvant chemotherapy and radiation therapy are used to downsize and downstage rectal cancers before definitive resection and improve overall survival and local disease control in stage II-III cancers.
- Adjuvant chemotherapy in stage II disease provides a modest improvement in overall survival by 3% to 4%, with current 5-yr survival rates in the 80% range. As such, current guidelines recommend consideration of adjuvant chemotherapy only in high-risk stage II patients. The magnitude of survival benefit is significantly higher in stage III patients, and combination chemotherapy is associated with 5-yr overall survival rate in the 70% range with wide variation in the subgroups. More recent data have revealed that low-risk stage III colon cancer patients may have equivalent survival with adjuvant multiagent chemotherapy of only 3 mo in duration.
- The outlook for patients with metastatic and relapsed CRC has improved dramatically in the past few yr. Median overall survival in patients with unresectable metastases is now expected in the 30-mo range with modern chemotherapeutic regimens. In patients with limited, resectable metastases in sites such as the liver, the 5-yr median overall survival is in the 50% range.
- Chemotherapy agents used in the metastatic setting include 5-fluorouracil (5-FU), capecitabine, irinotecan, oxaliplatin, and mitomycin. Chemotherapy regimens using a combination of antimetabolite (5-FU or capecitabine) in combination with either oxaliplatin or irinotecan form the backbone of systemic chemotherapy.
- Molecularly targeted therapy against the epidermal growth factor receptor (EGFR) and the angiogenesis pathway are used in combination with the chemotherapy backbone in metastatic CRC. Antiangiogenic agents include monoclonal antibodies bevacizumab, aflibercept, and ramucirumab. Cetuximab and panitumumab are EGFR receptor blockers that are active in metastatic CRC patients whose tumors do not harbor mutated RAS oncogenes.
- The liver is generally the initial and most common site of CRC metastases. Resection of liver-limited metastases followed by systemic combination chemotherapy is curative in more than 30% of selected patients. Metastasectomy of limited pulmonary metastases can also be considered in selected cases.
- Unresectable multiple liver metastases are often approached by locoregional therapeutic approaches such as transarterial chemoembolization (TACE), selective internal radiation therapy (SIRT) using yttrium-90 brachytherapy, or hepatic arterial infusional chemotherapy.
- The oral multitargeted kinase inhibitor regorafenib and the oral antimetabolite drug TAS-102 provide modest survival benefit in patients who have failed standard chemotherapy approaches.

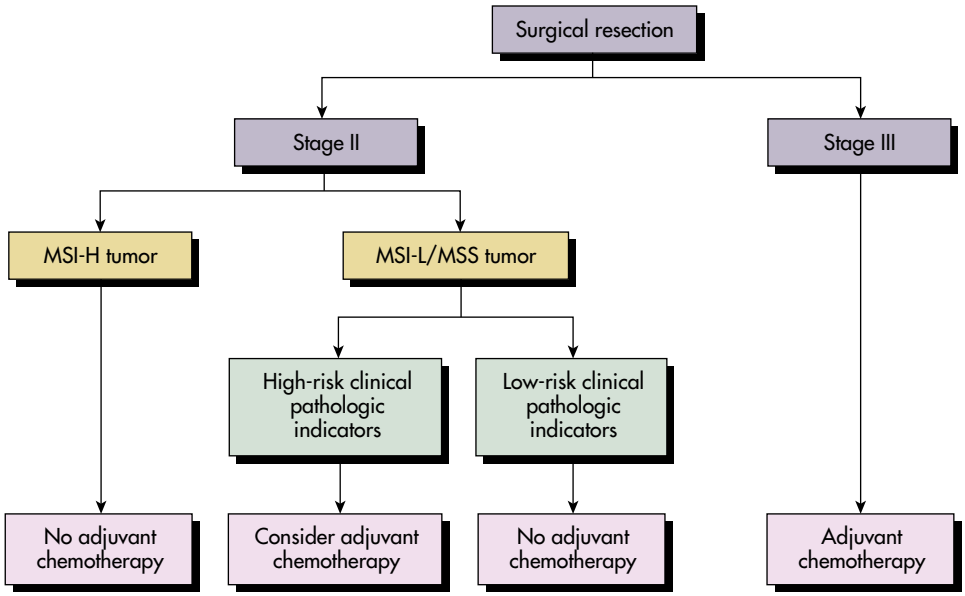

FIG. 5 Proposed algorithm for using microsatellite instability *(MSI)* alongside clinicopathologic factors in stages II and III colorectal cancer. ASCO guidelines: Inadequate samples nodes, T4 lesions, perforation, poorly differentiated histology. *MSI-H,* High-level microsatellite instability; *MSI-L/MSS,* low-level microsatellite instability/microsatellite stability. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

- Patients with tumors harboring BRAF mutations can now have improved survival with the use of combination molecularly targeted therapy consisting of encorafenib, binimetinib, and cetuximab.
- In patients with pathologically confirmed microsatellite instability in their cancers (Fig. 5), the checkpoint inhibitors (pembrolizumab, nivolumab) are effective options after failure of standard therapies and have been recently approved in this setting.
- Reviews of randomized trials in metastatic CRC have demonstrated that right-sided cancers are associated with shorter overall survival when compared with left-sided cancers.

CHRONIC Rx

Follow-up is indicated with:

- Physician visits with a focus on clinical and disease-related history, directed physical examination, coordination of follow-up, and counseling every 3 to 4 mo for the first 3 yr and then every 6 mo for 2 yr.
- Colonoscopy at end of first yr, then after 3 yr, and subsequently every 5 yr.
- Baseline CEA level, if elevated, can be used after surgery as a measure of completeness of tumor resection. It is used to monitor tumor recurrence and is obtained every 3 to 6 mo for up to 5 yr.

DISPOSITION

The 5-yr survival rate varies with the stage of the carcinoma:

TNM Stage	5-yr Survival Rate (%)
I	>90
II_{A-C}	60-85
III_{A-C}	25-65
IV	5-10

- Overall 5-yr disease-free survival rate has increased from 50% to 63% during the past two decades.
- High-frequency microsatellite instability in CRC is independently predictive of a relatively favorable outcome and reduces the likelihood of metastases.
- In patients with high-risk stage II and with stage III CRC, there is improved 5-yr survival among patients treated with adjuvant chemotherapy.
- Expression patterns of microRNA are systemically altered in colon adenocarcinomas. High miR-21 expression is associated with poor survival and poor therapeutic outcome.
- The optimal timing from surgery to initiation of adjuvant chemotherapy is 4 to 8 wk. A longer time to initiation of adjuvant chemotherapy is associated with worse survival rates.
- Regular aspirin use after the diagnosis of CRC has been reported to be associated with lower risk for CRC-specific and overall mortality, especially among individuals with tumors that overexpress cyclooxygenase-2. Regular aspirin use is associated with lower BRAF-wild type colorectal cancer but not with BRAF-mutated cancer risk. All aspirin doses starting with 75 mg daily had similar effects on CRC incidence and mortality.

REFERRAL

- Multidisciplinary referral to colorectal surgery or surgical oncology, medical oncology, radiation oncology

PEARLS & CONSIDERATIONS

COMMENTS

- Metastases of tumor cells to regional lymph nodes is the single most important prognostic factor in patients with colon cancer.
- Decreased fat intake to 30% of total energy intake, increased fiber through fruit and vegetable consumption may reduce CRC risk.
- Chemoprophylaxis with aspirin (81 mg/day) reduces the incidence of colorectal adenomas in persons at risk.
- The National Cancer Institute has published consensus guidelines for universal screening for HNPCC in patients with newly diagnosed CRC. Tumors in mutation carriers of HNPCC typically exhibit microsatellite instability, a characteristic phenotype caused by expansion or contraction of short nucleotide repeat sequences. These guidelines (Bethesda Guidelines) are useful for selective patients for microsatellite instability testing. Screening patients with newly diagnosed CRC for HNPCC is cost effective, especially if the benefits to their immediate relatives are considered.
- The use of either annual or biennial FOBT significantly reduces the incidence of CRC.
- The detection of mutations in the *APC* gene from stool samples is a promising new modality for early detection of colorectal neoplasms.

BASIC INFORMATION

DEFINITION

Compartment syndrome is a condition caused by elevated pressure within a confined myofascial space resulting in decreased perfusion, hypoxia, and potential necrosis of the involved tissues. Acute compartment syndrome is a surgical emergency necessitating prompt diagnosis and intervention.

ICD-10CM CODES: Code x Y (Y = encounter type: (A) initial, D (subsequent), S (sequelae)

T79.A0xA	Compartment syndrome, unspecified, initial encounter
T79.A0xD	Compartment syndrome, unspecified, subsequent encounter
T79.A0xS	Compartment syndrome, unspecified, sequelae
T79.A19xY	Traumatic compartment syndrome of unspecified upper extremity
T79.A11x Y	Traumatic compartment syndrome of the right upper extremity
T79.A12x Y	Traumatic compartment syndrome of the left upper extremity
T79.A29x Y	Traumatic compartment syndrome of unspecified lower extremity
T79.A21x Y	Traumatic compartment syndrome of right lower extremity
T79.A22x Y	Traumatic compartment syndrome of left lower extremity
T79.A9x Y	Traumatic compartment syndrome of other sites
M79.A19x Y	Nontraumatic compartment syndrome of unspecified upper extremity
M79.A11x Y	Nontraumatic compartment syndrome of the right upper extremity
M79.A12x Y	Nontraumatic compartment syndrome of the left upper extremity
M79.A29x Y	Nontraumatic compartment syndrome of unspecified lower extremity
M79.A21x Y	Nontraumatic compartment syndrome of right lower extremity
M79.A22x Y	Nontraumatic compartment syndrome of left lower extremity
M79.A9x Y	Nontraumatic compartment syndrome of other sites

EPIDEMIOLOGY & DEMOGRAPHICS

- Most commonly associated with acute trauma, comprising 70% of cases. Up to 30% of cases are not associated with a fracture.
- Typically occurs in persons <35 yr of age, with approximately 10× higher incidence in males.

PATHOPHYSIOLOGY

Compartment syndrome occurs when elevated pressure within a myofascial compartment impairs blood flow and results in tissue ischemia and necrosis. As intracompartmental pressure rises, it eventually exceeds the local capillary pressure, resulting in capillary bed collapse. Venous outflow is compromised, which results in venous congestion and subsequently decreased perfusion of oxygenated blood. Hypoxia, ischemia, and cell death ensue. Tissue perfusion has been shown to decrease significantly with intracompartmental pressures between 10 and 20 mm Hg. Decreased tissue perfusion can result in reversible neurapraxia within 1 hour, followed by cell death, myonecrosis, and other irreversible changes within 4 to 6 hours.

A variety of clinical conditions are associated with the development of compartment syndrome:

- Conditions that increase the volume within a compartment: Bleeding from fracture, vascular injury, or bleeding diathesis. It is possible to develop compartment syndrome even in the setting of an open fracture.
- Conditions that lead to significant soft-tissue swelling: Reperfusion injury, crush injury, high-energy soft-tissue injury (e.g., gunshot or ballistic injury), thermal or electrical burn injuries, extravasation of intravenous fluids, injection of recreational drugs, massive fluid resuscitation, and snake bites.
- Conditions that decrease the volume of a compartment via external forces: Tight external dressings (e.g., fracture casts/splints), prolonged downtime, or external pressure seen in sedated or comatose patients who lie on an extremity for a prolonged period (e.g., drug overdose, ICU patients, and prolonged surgical procedures).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical signs and symptoms of compartment syndrome include:

- Pain out of proportion for a given injury or worsening pain despite adequate or escalating analgesia requirement (earliest sign).
- Pain with passive stretch of the muscles within the compartment. Typically, patients describe severe pain localized to the affected compartment that is exacerbated by passive stretch of the muscles within the compartment. Many trauma patients will complain of pain with any movement of the affected extremity. Therefore it may be useful for providers to attempt to distract patients while testing for pain with passive stretch.
- Tense or swollen compartment that is firm to touch or noncompressible (Fig. E1).
- Numbness, tingling, or paresthesias in the sensory distribution of the nerve(s) traversing the compartment.
- Capillary refill can be sluggish or normal.
- Palpable peripheral pulses may be present even in late stages of the disease due to collateral blood flow and reconstitution distal to the compartment of concern.
- Pediatric patients may demonstrate the three As: Agitation, Anxiety, and increasing Analgesia requirement.

DIAGNOSIS

Compartment syndrome is a clinical diagnosis based on history and examination. Acute compartment syndrome can develop quickly or evolve over time, so serial examinations are critical for patients at risk. Typically, compartment syndrome will develop within 48 hours of injury. The diagnosis may be confirmed with the use of intracompartmental pressure-measuring devices if the clinical signs of compartment syndrome are unclear, such as in the setting of unreliable, comatose, or otherwise nonresponsive patients.

DIFFERENTIAL DIAGNOSIS

- Physiologic soft-tissue edema or swelling
- Muscle strain or contusion
- Cellulitis
- Gangrene
- Peripheral vascular injury
- Necrotizing fasciitis
- Stress fracture
- Deep vein thrombosis and thrombophlebitis
- Tendinitis
- Tarsal tunnel or posterior ankle syndrome

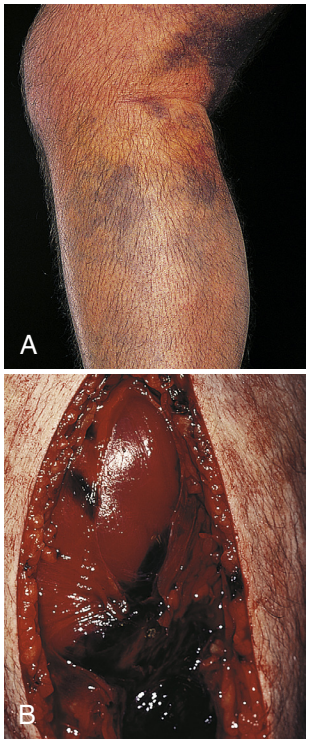

FIG. E1 A, Severe calf swelling due to anterior and posterior compartment syndromes after ischemia-reperfusion. **B,** Appearance after emergency fasciotomy. Note edematous muscle and hematoma. (Courtesy Michael J. Allen, FRCS, Leicester, UK. From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.)

- Popliteal artery impingement
- Claudication
- Tumor
- Venous insufficiency

LABORATORY TESTS

Laboratory values are not useful in the diagnosis of compartment syndrome but are important for other diagnoses or associated conditions.

- INR/PT and PTT to assess coagulation profile and bleeding diathesis
- CBC with differential for evaluation of infection
- Creatine phosphokinase (CK) levels, which can rise as muscle injury develops (e.g., crush injury, rhabdomyolysis)
- Metabolic panel for the assessment of electrolytes and renal function
- Urinalysis for rhabdomyolysis
- Urine and serum myoglobin levels

IMAGING STUDIES

- Radiographs of the affected extremity should be obtained to evaluate for fracture or foreign body.
- Direct intracompartmental pressure measurement can be obtained using a handheld manometer, wick or slit catheter technique, or a simple needle manometer system. Compartment syndrome is confirmed when the difference between diastolic blood pressure and compartment pressure (Δ pressure) is ≤30 mm Hg.
- Ultrasonography or Doppler ultrasonography can be used to rule out deep vein thrombosis and evaluate blood flow to the extremity. Arteriography can be used to evaluate for arterial injury and blood flow within a compartment.
- Near-infrared spectroscopy and technetium-99m methoxyisobutylisonitrile scintigraphy can also be used.

Rx TREATMENT

The goal of treatment is to reduce the intracompartmental pressure and prevent tissue ischemia and necrosis (Fig. E2).

ACUTE GENERAL Rx

- Analgesics for pain control.
- Advanced trauma life support (hypotension can worsen tissue perfusion and ischemia).
- Remove circumferential dressings, casts, and all external pressure generators.
- The affected extremity should be elevated above the level of the heart to aid in resolution of swelling.
- The standard of care is emergent fasciotomy and thorough debridement of nonviable tissue. This should be performed within 4 to 6 hours of symptom onset.
- Measurement of compartment pressure is not necessary to confirm diagnosis, and fasciotomy should not be delayed to obtain compartment pressures in the setting of high clinical suspicion.
- Associated fractures should be stabilized with internal or external fixation to reduce further soft tissue injury.

CHRONIC Rx

- Patients should return to the operating room every 48 hours to assess tissue viability and repeat debridement as needed.
- A negative pressure wound therapy system may be placed over fasciotomy wounds with delayed wound closure and skin grafting as needed.
- Local wound care should be emphasized to decrease the risk of infection.

DISPOSITION

With early diagnosis and prompt intervention, the prognosis and functional outcomes are excellent. The following are sequelae of delayed or undiagnosed compartment syndrome:

- Myonecrosis
- Permanent nerve damage and paralysis
- Muscle contracture (e.g., Volkmann contracture in the forearm)
- Gangrene
- Infection and possible sepsis
- Amputation
- Rhabdomyolysis and possible renal failure
- Cardiac arrhythmias and possible death from reperfusion injury and electrolyte abnormalities

REFERRAL

Patients with suspected compartment syndrome should be promptly referred to an orthopedic and general surgeon.

PEARLS & CONSIDERATIONS

- Compartment syndrome is a surgical emergency necessitating prompt diagnosis and intervention. It is commonly associated with fractures, most notably tibial shaft and both bone forearm fractures.
- Compartment syndrome is a clinical diagnosis, and intracompartmental pressure measurements are not required to make or confirm the diagnosis.
- Pain out of proportion to an injury, pain with passive stretch, or increasing analgesia requirement should raise concern for compartment syndrome.
- The presence of palpable peripheral pulses does not rule out compartment syndrome.
- Universal precautions and aseptic measures are necessary for patients undergoing fasciotomy due to the elevated risk of local and systemic infection following the procedure.
- Patients with fractures treated with a cast should be informed about the risks of swelling and the signs and symptoms of compartment syndrome with instructions to go to the nearest emergency department if these symptoms develop.

BASIC INFORMATION

DEFINITION

Complex regional pain syndrome (CRPS) is a pain disorder characterized by constant and intense limb pain associated with vasomotor and neurosensory abnormalities, skin changes, and demineralization of bone. CRPS has been divided into type I (about 90% of cases), in which there is usually an initiating noxious event but no distinct nerve injury, and type II, in which a definable (usually traumatic) nerve lesion exists. CRPS type I generally correlates with the syndrome formerly known as reflex sympathetic dystrophy (RSD), and CRPS type II equates with what was previously termed causalgia. The term *shoulder-hand syndrome* has been used to describe CRPS in the setting of myocardial infarction or ischemia.

SYNONYMS (BOX E1)

Reflex sympathetic dystrophy
Shoulder hand syndrome
CRPS

ICD-10CM CODES

M89.0	Algoneurodystrophy
G90.59	Complex regional pain syndrome I of other specified site
G90.511	Complex regional pain syndrome I of right upper limb
G90.512	Complex regional pain syndrome I of left upper limb
G90.513	Complex regional pain syndrome I of upper limb, bilateral
G90.519	Complex regional pain syndrome I of unspecified upper limb
G90.521	Complex regional pain syndrome I of right lower limb
G90.522	Complex regional pain syndrome I of left lower limb
G90.523	Complex regional pain syndrome I of lower limb, bilateral
G90.529	Complex regional pain syndrome I of unspecified lower limb
G90.59	Complex regional pain syndrome I of other specified site

BOX E1 Terms Used in the Definition of Complex Regional Pain Syndrome

Complex regional pain syndrome (CRPS) type I (the preferred term)
Causalgia (now CRPS type II)
Reflex sympathetic dystrophy (RSD)
Sudeck atrophy
Shoulder–hand syndrome
Algodystrophy
Algoneurodystrophy
Posttraumatic dystrophy
Posttraumatic osteoporosis
Painful osteoporosis
Transient osteoporosis

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: CRPS is rare (population prevalence less than 1 in 2000). One study in the Netherlands found an overall incidence of 26.2 per 100,000 person yr, with 3.4 times more women diagnosed than men.
PEAK INCIDENCE: Sixth decade, highest in postmenopausal women.
RISK FACTORS: Common situations in which CRPS is seen include extremity trauma, burns, stroke, and orthopedic and podiatric procedures. Fracture is the most common risk factor, and CRPS occurs more commonly in the upper extremity than in the lower. The incidence of CRPS may be increased when combined hand surgery procedures are performed. Immobilization of the limb often precedes the development of symptoms. CRPS in the setting of myocardial infarction seems to be decreasing, presumably due to early mobilization and more effective pain control.

PHYSICAL FINDINGS & CLINICAL PRESENTATION (TABLE E1)

CRPS is divided into three stages:

- Acute stage (can occur within hours of injury, usually within 4 to 6 weeks after event)
  1. Burning or aching pain occurring over the injured extremity
  2. Hyperalgesia (exaggerated response to nociceptive stimuli), allodynia
  3. Edema; motor impairment (due to pain)
  4. Dysthermia
  5. Increased hair and nail growth
- Dystrophic stage (3 to 6 months after injury)
  1. Burning pain radiating both distally and proximally from the site of injury
  2. Brawny edema (Fig. E1)
  3. Hyperhidrosis
  4. Hypothermia and cyanosis
  5. Muscle tremors and spasms
  6. Increased muscle tone and reflexes
- Atrophic stage (6 mo after injury)
  1. Spread of pain proximally
  2. Allodynia (pain response to stimuli that are not normally painful)
  3. Cold, pale, cyanotic skin
  4. Trophic skin changes with subcutaneous atrophy, brittle nails
  5. Contractures, limited movement

ETIOLOGY

The pathogenesis of CRPS remains unknown. Theories include the formation of an abnormal reflex arc in the sympathetic nervous system that is modulated by cortical centers to produce peripheral vascular disturbances. Persistent pain in the peripheral nervous system is modulated by inflammatory neuropeptides including substance P, which has been shown to be elevated in the serum of CRPS-I patients. Increased concentrations of tumor necrosis factor (TNF)-alpha, interleukin (IL)-6, and IL-2 have been demonstrated in tissue of patients with CRPS-I. Genetic factors may play a role (one study found increased HLA-DQ1 frequency in CRPS-I patients). Typical triggering events for CRPS are summarized in Table E2.

DIAGNOSIS

Criteria proposed for the diagnosis of CRPS type I include:

- An initiating noxious event, spontaneous pain or alloying/hyperalgesia disproportionate to the inciting event.
- Evidence of edema, skin blood flow, or sweating abnormality in the region of the pain.
- Absence of other conditions that could explain the symptoms.

There is no gold-standard test to confirm diagnosis, but triple-phase bone scans, nerve conduction testing, and bilateral radiographs are often used to confirm the diagnosis and assess for other possibilities.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes nerve entrapment syndromes such as cervical radiculopathy, myofascial pain syndromes, and fibromyalgia.

TABLE E1 Clinical Features of Complex Regional Pain Syndrome

Sensory	Pain, often burning, extending beyond the area of the original injury
	Allodynia
	Hyperalgesia or hyperpathia
	Disturbed body perception
Vasomotor	Color change*
	Temperature change*
Sudomotor or edema	Edema
	Increased sweating
Motor or trophic	Weakness or inability to initiate movement
	Tremor
	Muscle spasms
	Dystonic features
	Contractures
	Skin, hair, and nail changes

*Compared with the unaffected side.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

WORKUP

- Bone scintigraphy (Fig. E2) shows decreased perfusion of the affected areas if done soon after the onset of symptoms. If done after 6 weeks of symptoms, bone scan may show increased uptake in the region of the peripheral joints of the involved extremity.
- Electrophysiologic testing is useful to identify nerve injury in patients with type II CRPS.
- Plain radiographs show diffuse patchy osteopenia (Fig. E3).
- Repetitive skin temperature measurements can be used as a diagnostic test.
- Autonomic testing, although not commonly done, has been proposed.
  1. Measuring resting sweat output
  2. Measuring resting skin temperature
  3. Quantitative sudomotor axon reflex test

FIG. E1 Complex regional pain syndrome affecting the lower limb, showing marked swelling and color change. (Reproduced with permission from Salford Royal NHS Foundation Trust.)

Rx TREATMENT

Treatment of CRPS is largely empiric, based mostly on anecdotal reports, extrapolation from drug trials for other painful conditions, and clinical experience. Published studies are generally of low quality and show mixed results. Therapy should be tailored to stage of disease progression and severity of symptoms. Approaches to the treatment of CRPS are summarized in Table E3.

FIG. E2 Reflex sympathetic dystrophy in a patient with a history of right wrist fracture. Three-phase bone scintigraphy shows increased tracer delivery to the right distal upper extremity diffusely *(arrow)* on flow *(top)* and blood pool *(middle)* images. Delayed images *(bottom)* reveal diffuse abnormal uptake in the wrist *(arrow)* and increased activity in a juxtaarticular distribution *(arrowheads)*. (From DeLee D, Drez D: *DeLee and Drez's orthopaedic sports medicine,* ed 2, Philadelphia, 2003, Saunders.)

TABLE E2 Typical Triggering Events for Complex Regional Pain Syndrome

Trauma	Wrist fractures
	Tibial fractures
	Soft tissue injuries
Surgery	Carpal tunnel decompression
	Arthroscopy
	Lumbar spine surgery
Central nervous system or spinal disorders	Head injury
	Hemiplegia
Visceral lesions	Myocardial infarction

From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

NONPHARMACOLOGIC THERAPY

- Physical therapy
- Patient education
- Psychosocial assessment

PHARMACOLOGIC THERAPY

Suggested regimens:

- Early CRPS, one or more of the following:
  1. NSAIDs
  2. Tricyclic antidepressant, gabapentin, pregabalin
  3. Glucocorticoids (oral prednisone 30 to 60mg daily with taper)
  4. Bisphosphonates (oral alendronate, IV pamidronate)
  5. Topical capsaicin, topical lidocaine
- Resistant course, incomplete response also can consider:
  1. Alpha-adrenergic antagonists and agonists (prazosin, phenoxybenzamine, clonidine)
  2. Ketamine infusion
  3. Use of opioids is controversial, but low doses can be considered
  4. Regional nerve blocks, sympathetic ganglion blocks, sympathectomy
  5. Spinal cord stimulation, dorsal root ganglia stimulation
  6. Referral to multidisciplinary pain center

NOTE: High-dose vitamin C may decrease the incidence of CRPS following wrist fracture, foot and ankle surgery, or trauma.

DISPOSITION

Spontaneous remission can occur after weeks to months, but many have prolonged disability.

REFERRAL

Cases in which the diagnosis is not clear or there is suboptimal response to therapy should promptly be referred to a multidisciplinary pain clinic.

PEARLS & CONSIDERATIONS

COMMENTS

- CRPS is a common clinical entity without clear definition, pathophysiologic features, or treatment.
- Early mobilization in high-risk situations is important for prevention of CRPS.
- Prompt diagnosis and aggressive physical and pharmacologic therapy may prevent progression to chronic, intractable pain.
- Trials involving intravenous immunoglobulin (IVIG) have failed to show reproducible results for pain reduction in patients with moderate to severe CRPS.

BASIC INFORMATION

DEFINITION

- Concussion is a mild traumatic brain injury manifesting with self-limited symptoms at the less severe end of the brain injury spectrum.
- The fourth International Conference on Concussion (2012) defines concussion as "a complex pathophysiological process affecting the brain, induced by traumatic biomechanical forces," characterized by the following features: (1) Caused by a direct blow to the head or blow to the body that transmits an "impulsive" force to the head; (2) results in rapid onset of short-lived neurologic impairment that resolves spontaneously; (3) variable clinical symptoms that may not include loss of consciousness; (4) symptoms that largely reflect a functional disturbance rather than structural injury (thus, no abnormalities are seen on standard structural neuroimaging studies); and (5) symptom resolution that typically follows a sequential course but may be prolonged in a small percentage of cases.

SYNONYM

Mild traumatic brain injury (mTBI)

ICD-10CM CODES	
S06.0	Concussion
S06.0X0A	Concussion without loss of consciousness, initial encounter
S06.0X0D	Concussion without loss of consciousness, subsequent encounter
S06.0X0S	Concussion without loss of consciousness, sequela
S06.0X1A	Concussion with loss of consciousness of 30 minutes or less, initial encounter
S06.0X9A	Concussion with loss of consciousness of unspecified duration, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 3.8 million sports- and recreation-related concussions occur each yr in the U.S. It is estimated that as many as 50% of concussions go unreported.

PREVALENCE: Each yr, U.S. emergency departments treat an estimated 135,000 sports- and recreation-related TBIs, including concussions, among children ages 5 to 18.

PREDOMINANT SEX AND AGE:

- Children and teens are more likely to get a concussion and take longer to recover than adults.
- Limited studies have shown that in sports that are played by both men and women, women are at more risk of sustaining a concussion. In males the incidence is highest in football, followed by hockey, and in females, soccer. Player contact is the most common cause.

RISK FACTORS:

- Participating in high-impact sports and recreational activities
- Previous history of concussion
- Athletes with a body mass index (BMI) >27 kg/m^2 and those who train <3 hr/wk
- Individuals who sustain a sports-related concussion and continue playing immediately after the injury require nearly twice as much time to recover as those who are removed immediately

PHYSICAL FINDINGS & CLINICAL PRESENTATION

See Table 1.

ETIOLOGY

- Occurs when rotational or angular acceleration forces are applied to the brain, resulting in shear strain of the underlying neural elements, including altered autonomic function and impaired control of cerebral blood flow
- May be associated with a blow to the skull; however, direct impact to the head is not required

TABLE 1 Symptoms and Signs of Concussion

Mental Status Changes
Amnesia
Confusion
Disorientation
Easily distracted
Excessive drowsiness
Feeling dinged, stunned, or foggy
Impaired level of consciousness
Inappropriate play behaviors
Poor concentration and attention
Seeing stars or flashing lights
Slow to answer questions or to follow directions
Physical or Somatic
Ataxia or loss of balance
Blurry vision
Decreased performance or playing ability
Dizziness
Double vision
Fatigue
Headache
Light-headedness
Nausea, vomiting
Poor coordination
Ringing in the ears
Seizures
Slurred, incoherent speech
Vacant stare/glassy-eyed
Vertigo
Behavior or Psychosomatic
Emotional lability
Irritability
Low frustration tolerance
Personality changes
Nervousness, anxiety
Sadness, depressed mood

From Patel DR et al: Sports concussions in adolescents, *Pediatr Clin N Am* 57:652, 2010.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Migraine
- Cervical strain
- Posttraumatic vestibular injury

WORKUP

- There is no definitive diagnostic test for concussion. Physical exam should include smooth pursuits (examiner moves finger horizontally across field of vision), saccades, gaze instability, near point of convergence, accommodation, and balance. Patients with loss of consciousness or posttraumatic convulsive seizures should be transported to the emergency department.
- Sideline assessment:
  1. No athlete with a suspected concussion should return to play that day.
  2. Neurologic assessment using a standardized tool, such as s SCAT-3 (Sports Concussion Assessment Tool), which includes the BESS (Balance Error Scoring System), Maddocks Questions, and SAC (Standardized Assessment of Concussion).
  3. Monitor for deterioration; no athlete should be left alone.
- Office assessment:
  1. History focused on current symptoms. Consider using Postconcussion Symptom Checklist.
  2. Neurologic exam
     a. Gait/balance testing. Consider the Balance Error Scoring System (BESS)
     b. Cerebellar coordination: Finger-to-nose testing (tested on SCAT-3 card)
     c. Convergence of Accommodative Sufficiency
- Neurocognitive testing:
  1. Computer-based programs, such as ImPACT, ANAM, CogSport
  2. Neuropsychiatric testing administered by a neuropsychologist
- When used in combination, symptom assessment, balance assessment, and neurocognitive testing provide a sensitivity of >90% for the identification of concussion.
- Consider the Buffalo Concussion Treadmill Test, which identifies physiologic dysfunction in concussion, rules out other diagnoses, and can quantify a safe level of activity in concussion recovery.

IMAGING STUDIES

- CT imaging is not universally indicated and should be considered on an individual basis. It is indicated in any athlete with a rapidly changing or focal neurologic exam or with a suspected intracranial bleed.
- Consider following PECARN guidelines.

TREATMENT

ACUTE GENERAL Rx

- Removal from game
- Physical rest

TABLE 2 Graduated Return to Play Protocol

Rehabilitation Stage	Functional Exercise at Each Stage of Rehabilitation	Objective of Each Stage
1. No activity	Complete physical and cognitive rest	Recovery
2. Light aerobic exercise	Walking, swimming, or stationary cycling, keeping intensity <70% maximum predicted heart rate. No resistance training	Increase heart rate
3. Sport-specific exercise	Skating drills in ice hockey, running drills in soccer. No head impact activities	Add movement
4. Noncontact training drills	Progression to more complex training drills, e.g., passing drills in football and ice hockey. May start progressive resistance training	Exercise, coordination, and cognitive load
5. Full contact practice	After medical clearance, participate in normal training activities	Restore confidence and assess functional skills by coaching staff
6. Return to play	Normal game play	

From Putukian M: The acute symptoms of sports-related concussion: diagnosis and on-field management, *Clin Sports Med* 30(58), 2011.

1. No return to play until asymptomatic for at least 24 hours.
2. Follow the return-to-play guidelines (Table 2).
3. There is no evidence to support prolonged rest in concussed athletes longer than several weeks (see "Postconcussive Syndrome"). Prolonged inactivity after concussion has been linked to negative health effect. Light aerobic activity that avoids risk for reinjury decreases concussion symptoms, suggesting that low-level physical activity postconcussion might be beneficial.

- Cognitive rest to limit symptoms
  1. Limit screen time to less than 2 hours per day.
  2. Academic accommodations at school. Consider return to school for half-days when tolerating 2 hours of work at home.
  3. Encourage good sleep hygiene.

CHRONIC Rx

See "Postconcussive Syndrome."

DISPOSITION

- Physiologic recovery is slower than symptomatic recovery. Protocols involving a symptom-free waiting period before return to play are warranted. Table 2 summarizes the American Academy of Neurology, American Medical Society for Sports Medicine, and International Conference on Concussion recommendations on returning to play after a concussion.
- If concussion symptoms occur with activity at one level, the athlete should stop the activity, rest until symptoms resolve, and then restart his or her progression at the level that did not elicit symptoms.
- There are no evidence-based guidelines for disqualifying or retiring an athlete from sport after a concussion. Each case should be individually considered.

REFERRAL

Referral to sports-medicine physician, neuropsychology, or concussion center is indicated if there is concern about the timing of return to contact or collision sport. Referral is also indicated in patients with preexisting neurologic disorders such as migraines, depression or anxiety, and in those who have had multiple concussions.

PEARLS & CONSIDERATIONS

PREVENTION

- Pre-participation evaluations for all athletes.
- Pre-participation neurocognitive and balance testing to establish a baseline.
- There is currently no evidence to support the use of concussion prevention headbands or mouth guards.
- Spontaneous recovery from acute concussion ranges from 1 to 2 weeks in adults and up to 4 weeks in adolescents.

Conduct Disorder

BASIC INFORMATION

DEFINITION

Conduct disorder (CD) is a repetitive and persistent pattern of behaviors in which either the basic rights of others are violated and/or major age-appropriate societal rules are violated. Classified under the DSM-5 category "disruptive, impulse control, and conduct disorders."

ICD-10CM CODES	
F43.24	Adjustment disorder with disturbance of conduct
F43.25	Adjustment disorder with mixed disturbance of emotions and conduct
F91.0	Conduct disorder confined to family context
F91.1	Conduct disorder, childhood-onset type
F91.2	Conduct disorder, adolescent-onset type
F91.8	Other conduct disorders
F91.9	Conduct disorder, unspecified
I45.89	Other specified conduction disorders
I45.9	Conduction disorder, unspecified
DSM-5 CODES	
312.81	Childhood onset
312.32	Adolescent onset
312.89	Unspecified onset

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1% (12 mo span, National Comorbidity Survey-Replication [NCS-R])

PREVALENCE: Approximately 2% to 10%; NCS-R: 9%. Disruptive behavior disorders are considered the most common reason for referral of children to mental health providers.

PREDOMINANT SEX: More common in males (4:1 preadolescence and 2:1 post-adolescence). It is unclear if CD females are underrepresented because diagnostic criteria were validated on male samples. Nonconfrontational aggression and promiscuity are examples of possible gender-specific criteria that, at this time, have unknown predictive validity.

PREDOMINANT AGE: Most common onset in early adolescence. Median age of onset is 11 yr.

GENETICS: Risk increased if parent or sibling with disorder.

RISK FACTORS: There are various temperamental (including lower-than-average intelligence, especially verbal), family-level (including parental rejection or neglect, early institutional living, frequent caregiver changes, large family size, parental criminality or substance use), and community-level (including peer rejection, association with delinquent peer group, exposure to violence) risk factors. A history of traumatic brain injury also confers risk for conduct disorder.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The DSM-5 lists 15 possible behavioral manifestations of CD, grouped into four categories: Aggression to people and animals, destruction of property, deceitfulness or theft, and serious violations of rules. Three of the 15 behaviors are required to have occurred in the previous 12 mo, and one behavior must have occurred in the previous 6 mo.
- Specifiers describe the age of onset and the severity of the disorder.
- New to the DSM-5 is an additional specifier addressing issues relating to intent and reaction to the behaviors, including the following options: "With limited prosocial emotions," "lack of remorse or guilt," "callous lack of empathy," "unconcerned about performance," and "shallow or deficient affect."
- CD represents a heterogeneous group with respect to presentation, etiology, severity, and course.
- Symptom severity often progresses over time with age (i.e., lying and truancy to sexual assault and robbery).
- Aggressive youth are more likely to interpret as negative or hostile the intent of neutral others and are more likely to believe that conflict can be adequately resolved via aggression.
- Poor frustration tolerance, irritability, temper outbursts, and recklessness are often associated with CD.
- Slow resting heart rate associated with reduced autonomic response to fear is the most replicated of all biologic markers for conduct problems.

ETIOLOGY

Estimated population variance in antisocial behavior accounted for by:

- Genes: 50%
- Environmental factors shared among family members: 20%
- Environmental factors unshared among family members: 20% to 30%

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Oppositional defiant disorder
- ADHD
- Mood disorder
- Adjustment disorder
- Substance use disorder, intoxication, or withdrawal
- Posttraumatic stress disorder
- Antisocial personality disorder (for those >18 yr)
- Adaptive behavior or subcultural delinquency
- Underlying neurological disorder (rare)

WORKUP

Diagnosis is made based on history, including individual and family interviews as well as collateral data from additional sources (e.g., parents, teachers, other medical providers, therapists).

LABORATORY TESTS

Consider urine toxicology for possible substance use comorbidity.

IMAGING STUDIES

None indicated; however, both structural and functional differences have been noted in certain areas of the brain in individuals with CD.

TREATMENT

Initial treatment of CD should include psychosocial and environmental interventions aimed at decreasing the frequency and severity of delinquent behaviors. If the interventions listed here are not effective or if serious concerns exist regarding safety or impairment in functioning, pharmacologic interventions targeting specific symptoms (e.g., aggression) or comorbid disorders (e.g., ADHD, anxiety disorders, or mood disorders) may help. There are currently no medications approved by the FDA for the treatment of CD.

NONPHARMACOLOGIC THERAPY

- Parent management training.
- Cognitive problem-solving skills training (including elements of social skills, conflict resolution, anger management, impulse control, and vocational training).
- Multisystemic therapy (MST).
- Social skills training.
- Individual psychotherapy.
- Family psychotherapy.
- Higher levels of care such as a hospital or acute residential setting may be required for stabilization if acute safety concerns develop in the context of CD, such as severe aggression.
- Legal involvement or out-of-home-placements may be necessary to monitor safety of both the patient and the community.

PHARMACOLOGIC THERAPY

Medication may be considered as an adjunct to behavioral treatment or in cases in which comorbidity is a factor. There is some evidence for symptom improvement with trials of several classes of psychotropic medications—including stimulants, mood stabilizers, atypical antipsychotics, antidepressants, and alpha-2 agonists—all of which seem to target aggressive symptoms in particular; medication, however, should never be used alone or as first-line treatment for CD.

DISPOSITION

- Approximately half of those with early onset of CD persist with antisocial behaviors into adulthood. There is no reliable way to predict which 50% will persist.
- Approximately half of those with early onset of CD do not develop antisocial personality disorder in adulthood. This subgroup is at higher risk for depression, anxiety, and social isolation as adults.
- Approximately 85% of those with adolescent onset of CD do not demonstrate lifetime persistent violence, convictions, and incarcerations. However, adult prognosis may often include substance use and crimes that go largely undetected.

PEARLS & CONSIDERATIONS

COMMENTS

- Treatment noncompliance is common (expect 30% treatment noncompliance rate).
- Consider community-based resources (including unique strengths of patient and family) and recruit multiple multidisciplinary team members to create the most effective possible treatment plan.

Condyloma Acuminatum PTG

BASIC INFORMATION

DEFINITION

Condyloma acuminatum, also known as anogenital warts, is a sexually transmitted viral disease of the penis, vulva, vagina, cervix, perineum, and perianal area caused by the human papillomavirus (HPV). More than 100 subtypes of the HPV virus have been identified, yet 90% of genital warts are caused by HPV types 6 or 11.

SYNONYMS

Genital warts
Venereal warts
Anogenital warts

ICD-10CM CODE
A63.0 Anogenital (venereal) warts

EPIDEMIOLOGY & DEMOGRAPHICS

- The estimated prevalence rate of HPV anogenital infection in the U.S. adult population is 10% to 20% among unvaccinated individuals
- Seen mostly in young adults, with peak age of onset of 16 to 25 yr
- A sexually transmitted disease spread by skin-to-skin contact
- Highly contagious, with 75% of sexually active adults in the United States having been infected with at least one genital HPV type at some time
- Virus shed from both macroscopic and microscopic lesions
- Average incubation time is 2 mo (range, 1 to 8 mo)
- Predisposing conditions: Diabetes, pregnancy, local trauma, and immunosuppression (e.g., transplant recipients, those with HIV infection)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Usually found in genital area but can be present elsewhere on the body (larynx, oropharynx, trachea, and extremities)
- Lesions usually in similar positions on both sides of perineum
- Initial lesions are pedunculated, soft papules about 2 to 3 mm in diameter, 10 to 20 mm long; may occur as single papule or in clusters
- Size of lesions varies from pinhead to large cauliflower-like masses (Fig. E1)
- Usually asymptomatic, but if infected can cause pain, odor, or bleeding
- Vulvar condyloma more common than vaginal and cervical
- Four morphologic types: Condylomatous, keratotic, papular, and flat warts
- Intra-anal warts are observed predominantly in persons who have had receptive anal intercourse

ETIOLOGY

- HPV is a group of nonenveloped, double-stranded DNA viruses belonging to the family Papillomaviridae.
- HPV DNA types 6 and 11 usually found in exophytic warts and have no malignant potential. 90% of genital warts are caused by HPV 6 and 11.
- HPV types 16 and 18 usually found in flat warts and are associated with increased risk of malignancy.
- Recurrence associated with persisting viral infection of adjacent normal skin in 25% to 50% of cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Molluscum contagiosum
- Seborrhea keratosis
- Fordyce spots
- Lichen planus
- Lichen nitidus
- Condylomata lata of syphilis
- Malignancy
- Abnormal anatomic variants or skin tags around labia minora and introitus
- Dysplastic warts
- Table 1 summarizes treatment options for anal warts

WORKUP

- Colposcopic examination of lower genital tract from cervix to perianal skin with 3% to 5% acetic acid
- Biopsy of vulvar lesions that lack the classic appearance of warts and that become ulcerated or do not respond to treatment
- Biopsy of flat, white, or ulcerated cervical lesions

LABORATORY TESTS

- HPV tests are available to detect oncogenic types of HPV infection and are used in the context of cervical cancer screening and management or follow-up of abnormal cervical cytology or histology
- Cervical cultures for *Neisseria gonorrhoeae* and Chlamydia
- Serologic test for syphilis
- HIV testing offered
- Wet mount or DNA testing for trichomoniasis, *Candida albicans*, and *Gardnerella vaginalis* (if patient has abnormal vaginal discharge)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cryotherapy with liquid nitrogen
- Surgical removal

ACUTE GENERAL Rx

Factors that influence selection of treatment include wart size, wart number, anatomic site of wart, wart morphology, patient preference, cost of treatment, convenience, adverse effects, and provider experience.

Keratolytic agents:

- Podophyllin (Podofilox 0.5% solution or gel)
  1. Acts by poisoning mitotic spindle and causing intense vasospasm
  2. Applied by patient directly to lesion weekly and washed off in 6 hours
  3. Used in minimal vulvar or anal disease
  4. Applied cautiously to nonkeratinized epithelial surfaces
  5. Contraindicated in pregnancy
  6. Discontinued if lesions do not disappear in 6 wk; switch to other treatment
- Sinecatechins 15% ointment (green tea flavonoid extracts)
  1. Acts by upregulating apoptosis-associated genes
  2. Applied by patient three time daily (0.5 cm strand of ointment to each wart)
  3. Should not be continued longer than 16 wk
- Trichloroacetic acid (30% to 80% solution)
  1. Acts by destruction of the warty lesions through precipitation of surface proteins
  2. Applied weekly to lesion by a trained clinician
  3. Indicated for vulvar, anal, and vaginal lesions; can be used for cervical lesions
  4. Less painful and irritating to normal tissue than podophyllin
- 5-Fluorouracil
  1. Acts by causing necrosis and sloughing of growing tissue
  2. Can be used intravaginally or for vulvar, anal, or urethral lesions
  3. Better tolerated; 3 g (two thirds of vaginal applicator) applied weekly for 12 wk
  4. Possible vaginal ulceration and erythema
  5. Patient's vagina examined after four to six applications
  6. 80% cure rate

Physical agents:

- Cryotherapy with liquid nitrogen or cryoprobe
  1. Acts by causing tissue damage by formation of ice crystals, leading to disruption of cell membranes and cell death
  2. Can be used weekly for 3 to 6 wk
  3. 62% to 79% cure rate
  4. Not suitable for large warts
- Laser therapy
  1. Done by physician with necessary expertise and equipment
  2. Painful; requires anesthesia
- Electrocautery or excision
  1. For recurrent, very large lesions
  2. Local anesthesia needed

Immunotherapy:

- Interferon A
  1. Injected intralesionally at a dose of 3 million U/m^2 three times weekly for 8 wk
  2. Side effects: Fever, chills, malaise, headache
- Imiquimod 5% cream: Immunomodulatory drug that increases the immune response to warts
  1. Applied by patient at night, 3× per wk; wash off after 6 to 10 hours
  2. Usage for 16 wk maximum
  3. Increases wart clearance after 3 mo
- 40% to 77% cure rate
- Interferon, topical: Increases wart clearance at 4 wk

TABLE 1 Treatment Options for Anal Warts

Treatment	Success Rate	Comments
Podophyllin	20%-50%	May need repeat applications
		Skin irritation can occur
		Not used in the anal canal
		Poorly absorbed by keratinized lesions (most chronic warts are keratinized)
Trichloroacetic or dichloroacetic acid	75%	Can be used in the anal canal
		Care is required to control the size of the slough
Cryotherapy	75%	Can be used in the anal canal
		Care is required to limit the size of the wound
		Fumes from the therapy can contain active HPV*
Topical 5-fluorouracil	50%-75%	Probably better used after surgical excision to decrease the frequency of recurrence
Imiquimod	75% in women 33% in men	Cannot be used in the anal canal; works better in women than in men
Surgical excision (usually combined with cautery)	60%-90%	Fumes from the cautery may contain HPV*
		May need to be done in more than one session to avoid excising or burning excessive anoderm if a thick carpet of lesions is present
Intralesional interferon-α	>70%	Injected into the base of up to 5 warts 3 times a wk for 3-8 wk
		Approved by the FDA for refractory condyloma
HspE7	Experimental	Promising treatment involving subcutaneous injections
		Fusion protein that combines immune-stimulating properties and a target antigen from HPV
External-beam radiation therapy	Variable	Reserved for giant cavitating condyloma (Buschke-Löwenstein lesions)
		Used as a last resort, usually when bleeding or tissue invasion cannot be controlled

*The risk of HPV transmission from such fumes is unknown.
FDA, Food and Drug Administration; HPV, human papillomavirus.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

DISPOSITION

- Most genital warts resolve without therapy.
- Follow-up exam every 6 to 12 mo as needed.
- Referral to a specialist experienced in the treatment of anogenital warts (e.g., dermatologist, urologist, or colorectal surgeon) is appropriate for patients who are immunosuppressed or who have treatment-refractory anogenital warts.
- Patients with large, bulky perianal or genital warts that may require extensive surgical removal should be referred to a colorectal surgeon or urologist.

PREVENTION

- Male and female condoms should be used consistently and correctly to lower the risks of acquiring and transmitting HPV. However, because HPV can infect areas not covered by a condom, condoms will not fully protect against HPV.
- New guidelines for the routine vaccination of young adolescents (females and males) ages 9 to 14 are two doses of the HPV vaccine given at a 6- to 12-mo interval, which offers the same protection as the three-dose vaccination.
- Young women from ages 15 to 26 should receive three doses of the HPV vaccine (the 9vHPV, 4vHPV, and 2vHPV are approved for females).
- Young males from ages 15 to 21 should receive three doses of the HPV vaccine. The age limit for male HPV vaccination may be extended up to age 26 (only the 4vHPV and 9vHPV vaccines are approved for males). For men who have sex with men (including young men who identify as gay and bisexual), for young transgender adults, and for young adults who are immunocompromised (secondary to HIV, chronic steroid usage, or prior history of transplant), HPV vaccination is recommended up to age 26. Three-dose HPV vaccination series are administered as IM injections over a 6-mo period, with the second and third doses given 1 to 2 and 6 mo after the first dose, respectively. The same vaccine type should be used for the entire three-dosage series.
- 4vHPV (Gardasil) vaccinates against types 6, 11, 16, and 18, which account for 66% of all cervical cancers.
- 2vHPV (Cervarix) vaccinates against types 16 and 18 (licensed for females only).
- 9vHPV (Gardasil 9) vaccine is available for preventing infection against HPV types 6, 11, 16, 18, 31, 33, 45, 52, and 58. It offers protection against five additional types of HPV accounting for 15% of cervical cancers not covered by Gardasil or Cervarix.
- HPV vaccines are not recommended for use in pregnant women.

Congenital Adrenal Hyperplasia

BASIC INFORMATION

DEFINITION

Congenital adrenal hyperplasia (CAH) is a spectrum of disorders resulting from a deficiency or complete lack of one of the enzymes in the cortisol synthesis pathway. These autosomal recessive genetic disorders are usually characterized by cortisol deficiency and virilization, with or without salt wasting.

SYNONYMS

CAH
21-Hydroxylase deficiency (equivalent to CYP21A2 deficiency)
11β-Hydroxylase deficiency
3β-Hydroxysteroid dehydrogenase deficiency
17-Hydroxylase deficiency
Lipoid adrenal hyperplasia
Adrenal virilism
Adrenogenital syndrome
Virilizing adrenal hyperplasia

ICD-10CM CODE
E25.0 Congenital adrenogenital disorders associated with enzyme deficiency

EPIDEMIOLOGY & DEMOGRAPHICS

- About 95% of cases of CAH are caused by 21-hydroxylase deficiency, of which two-thirds are the salt-wasting form. Table E1 summarizes genotype-phenotype correlations in congenital adrenal hyperplasia owing to 21-hydroxylase deficiency.
- Autosomal recessive inheritance.
- The "classic" form presents in childhood, and the "nonclassic" form is the mild, late-onset form.
- Incidence is estimated at about 1:10,000 to 1:20,000 live births (Hispanic > American Indian > white > black > Asian).
- Most common cause of ambiguous genitalia in 46,XX females.

CLINICAL PRESENTATION

"Classic" salt-wasting form (impaired cortisol and aldosterone synthesis):
- Adrenal crisis in first weeks of life with vomiting, poor weight gain, lethargy, dehydration, hyponatremia, hyperkalemia, and elevated plasma renin.
- Females are born with ambiguous genitalia (Fig. E1) that often leads to diagnosis before adrenal crisis occurs.
- Males may have greater penile size and smaller testes than expected during childhood. Males may also develop adrenal rests, or ectopic islands of adrenal cortical tissue in the testes, in childhood and may experience infertility as adults.
- If patients survive infancy, their overall life expectancy is not compromised.
- Both males and females may exhibit rapid growth in childhood due to early epiphyseal closure, which then results in short stature in adulthood.
- Precocious puberty is common in both males and females.

"Classic" non–salt-wasting or simple virilizing form (impaired cortisol synthesis only):
- Females present with ambiguous genitalia at birth.
- The normal appearance of male genitalia in the simple virilizing form makes this a difficult diagnosis in male infants.
- Characterized by precocious puberty, short stature, and testicular adrenal rests, as in the salt-wasting form.

"Nonclassic" or mild, late-onset form (varying degrees of androgen excess):
- Usually presents in adolescence or adulthood and is not detected on newborn screening
- Often asymptomatic but can be associated with mild virilization
- PCOS-like symptoms occur in women (hirsutism, oligomenorrhea, acne, infertility, insulin resistance, and abnormal menses)
- Associated with infertility in males

ETIOLOGY

In 21-hydroxylase deficiency, the pathways for aldosterone production (from the conversion of progesterone to deoxycorticosterone) and cortisol production (from the conversion of 17-hydroxyprogesterone to 11-deoxycortisol) by the cP450 enzyme 21-hydroxylase are interrupted. The production of ACTH is thus stimulated by a negative feedback mechanism, leading to adrenal hyperplasia and mineralocorticoid deficiency as the intermediaries in aldosterone and cortisol synthesis are shunted to the androgen biosynthesis pathway. A recombination event between the active *CYP21A2* gene on chromosome 6p21.3 and the CYP21A1 pseudogene is thought to create the deficient 21-hydroxylase enzyme.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Precocious puberty
- Polycystic ovarian syndrome (PCOS)
- Androgen resistance syndromes
- Pseudohermaphroditism
- Mixed gonadal dysgenesis
- Testicular carcinoma
- Leydig cell tumors
- Adrenocortical carcinoma
- Addison disease
- Pituitary adenoma

LABORATORY TESTS

- Prenatal: Chorionic villus sampling for history; genetic testing or measurement of 17-hydroxyprogesterone if family history.
- Serum 17-hydroxyprogesterone level, which is included in the newborn screen in all states, is the first-line test for suspected CAH.
- Adrenocorticotropin (ACTH) stimulation test is the next step to confirm the diagnosis and identify type of CAH.
- Additional tests that may be useful include plasma renin activity, aldosterone level, and electrolytes.

TABLE E1 Genotype-Phenotype Correlations in Congenital Adrenal Hyperplasia Owing to 21-Hydroxylase Deficiency

Mutation Group	A	B	C
Enzymatic activity, % normal	Nil	1–2%	20–50%
CYP21 mutations (phenotype generally corresponds to the least affected allele)	Gene deletion Exon 3 del 8 bp Exon 6 cluster Q318X R356W Intron 2 splice*	I172N	P30L V281L P453S
Severity	Salt wasting	Simple virilizing	Nonclassic
Aldosterone synthesis	Low	Normal	Normal
Age at diagnosis (without newborn screening)	Infancy	Infancy (females) Childhood (males)	Childhood to adulthood, or asymptomatic
Virilization	Severe	Moderate to severe	None to mild
Incidence	1/20,000	1/50,000	1/500

*This mutation is associated with both salt wasting and simple virilizing disease.
From Kliegman, RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

IMAGING STUDIES

- Abdominal ultrasound (Fig. E2) to evaluate adrenal glands can accelerate diagnosis.
- Ultrasound to identify a uterus in cases of ambiguous genitalia.
- Ultrasound is preferred to rule out testicular adrenal rest tumors (found in classic and nonclassic forms) and should be done beginning in adolescence.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Surgical correction of ambiguous genitalia may be necessary.
- Monitoring: Serum 17-hydroxyprogesterone and androstenedione, renin, electrolytes, blood pressure, bone age and density, Tanner staging, growth velocity, weight.
- Bilateral laparoscopic adrenalectomy with lifelong glucocorticoid and mineralocorticoid replacement (controversial).
- Gene therapy (hypothetical).
- Psychological counseling.

CHRONIC Rx

- Glucocorticoids to partially suppress adrenal androgen secretion. During periods of physiologic stress, they may need to be doubled or tripled.
  1. In children, hydrocortisone is preferred because of its short half-life, which minimizes the risk of iatrogenic short stature. After patients are fully grown, long-acting glucocorticoids can be used.
  2. Adolescents and adults: Dexamethasone 0.25 to 0.75 mg PO QHS (also used to treat adrenal rests) or prednisone 5 to 7.5 mg/day in two divided doses.
- Mineralocorticoids (e.g., fludrocortisone) to normalize electrolytes and plasma renin activity.
  1. In infants, salt supplementation is also required.
- Treatment of simple virilizing form: Similar to salt-wasting form, but mineralocorticoid replacement is unnecessary.
- Treatment of nonclassic form:
  1. In adolescent and adult women: Oral contraceptives, glucocorticoids, and/or antiandrogens.
  2. In children and adult males, usually no treatment is necessary.
  3. Prenatal glucocorticoid treatment is controversial but may decrease virilization in female fetuses.

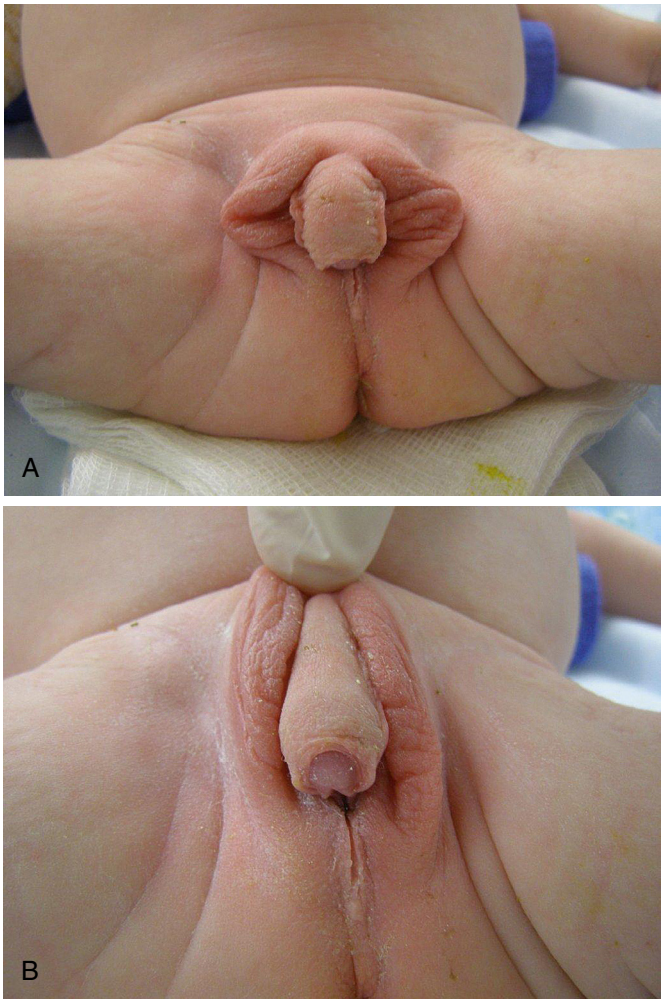

FIG. E1 Congenital adrenal hyperplasia. This newborn has ambiguous genitalia. Note the marked clitoral enlargement (resembling a penis), the rugated and partially fused labia majora **(A)**, and the common opening between the vagina and the urethra (urogenital sinus) **(B)**. (Courtesy Marleta Reynolds, MD. From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

PEARLS & CONSIDERATIONS

COMMENTS

- Consider the diagnosis of classic salt-wasting CAH in infants with failure to thrive.
- There is believed to be an increased prevalence of CAH in patients diagnosed with adrenal "incidentalomas"—adrenal gland lesions detected unexpectedly on imaging, usually by MRI or CT scanning.

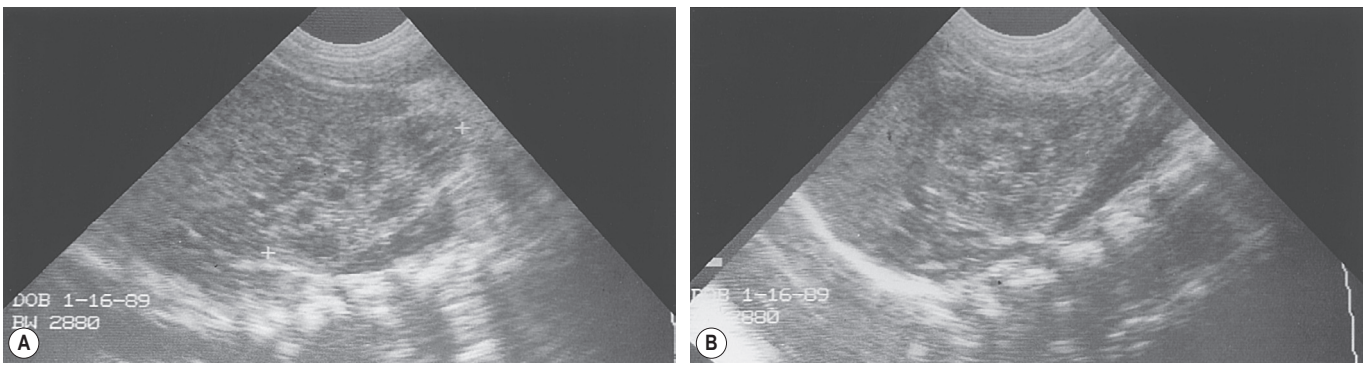

FIG. E2 Congenital adrenal hyperplasia in a patient with male pseudohermaphroditism. Sagittal US of the **(A)** right and **(B)** left adrenal glands demonstrates masslike enlargement. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, 2019, Elsevier.)

- Cushing syndrome may result from overtreatment of CAH with glucocorticoids.
- Patients with CAH may have gender dysphoria and sexual dysfunction.
- Table E2 summarizes diagnosis and treatment of CAH.

PREVENTION

- Prenatal: Early CVS sampling. Use of dexamethasone 20 to 25 mg/kg daily beginning at 5- to 8-wk gestation for female fetuses only is controversial because long-term studies are unavailable
- Neonatal screening
- Genetic counseling

AUTHOR: **Fred F. Ferri, MD**

TABLE E2 Diagnosis and Treatment of Congenital Adrenal Hyperplasia

Disorder	Affected Gene and Chromosome	Signs and Symptoms	Laboratory Findings	Therapeutic Measures
21-Hydroxylase deficiency, classic form	*CYP21* 6p21.3	Glucocorticoid deficiency	↓ Cortisol, ↑ACTH ↑↑ Baseline and ACTH-stimulated 17-hydroxy-progesterone	Glucocorticoid (hydrocortisone) replacement
		Mineralocorticoid deficiency (salt-wasting crisis)	Hyponatremia, hyperkalemia ↑ Plasma renin	Mineralocorticoid (fludrocortisone) replacement; sodium chloride supplementation
		Ambiguous genitalia in females	↑ Serum androgens	Vaginoplasty and clitoral recession
		Postnatal virilization in males and females	↑ Serum androgens	Suppression with glucocorticoids
21-Hydroxylase deficiency, nonclassic form	*CYP21* 6p21.3	May be asymptomatic; precocious adrenarche, hirsutism, acne, menstrual irregularity, infertility	↑ Baseline and ACTH-stimulated 17-hydroxyprogesterone ↑ Serum androgens	Suppression with glucocorticoids
11β-Hydroxylase deficiency	*CYP11B1* 8q24.3	Glucocorticoid deficiency	↓ Cortisol, ↑ ACTH ↑↑ Baseline and ACTH-stimulated 11-deoxycortisol and deoxycorticosterone	Glucocorticoid (hydrocortisone) replacement
		Ambiguous genitalia in females	↑ Serum androgens	Vaginoplasty and clitoral recession
		Postnatal virilization in males and females	↑ Serum androgens	Suppression with glucocorticoids
		Hypertension	↓ Plasma renin, hypokalemia	Suppression with glucocorticoids
3β-Hydroxysteroid dehydrogenase deficiency, classic form	*HSD3B2* 1p13.1	Glucocorticoid deficiency	↓ Cortisol, ↑ ACTH ↑↑ Baseline and ACTH-stimulated Δ5 steroids (pregnenolone, 17-hydroxy-pregnenolone, DHEA)	Glucocorticoid (hydrocortisone) replacement
		Mineralocorticoid deficiency (salt-wasting crisis)	Hyponatremia, hyperkalemia ↑ Plasma renin	Mineralocorticoid (fludrocortisone) replacement; sodium chloride supplementation
		Ambiguous genitalia in females and males	↑ DHEA, ↓ androstenedione, testosterone, and estradiol	Surgical correction of genitals and sex hormone replacement as necessary, consonant with sex of rearing
		Precocious adrenarche, disordered puberty	↑ DHEA, ↓ androstenedione, testosterone, and estradiol	Suppression with glucocorticoids
17α-Hydroxylase/17,20-lyase deficiency	*CYP17* 10q24.3	Cortisol deficiency (corticosterone is an adequate glucocorticoid)	↓ Cortisol, ↑ ACTH ↑ DOC, corticosterone Low 17α-hydroxylated steroids; poor response to ACTH	Glucocorticoid (hydrocortisone) administration
		Ambiguous genitalia in males	↓ Serum androgens; poor response to hCG	Orchidopexy or removal of intraabdominal testes; sex hormone replacement consonant with sex of rearing
		Sexual infantilism	↓ Serum androgens or estrogens	Sex hormone replacement consonant with sex of rearing
		Hypertension	↓ Plasma renin; hypokalemia	Suppression with glucocorticoids

Continued

TABLE E2 Diagnosis and Treatment of Congenital Adrenal Hyperplasia—cont'd

Disorder	Affected Gene and Chromosome	Signs and Symptoms	Laboratory Findings	Therapeutic Measures
Congenital lipoid adrenal hyperplasia	*STAR* 8p11.2	Glucocorticoid deficiency	↑ ACTH Low levels of all steroid hormones, with decreased or absent response to ACTH	Glucocorticoid (hydrocortisone) replacement
		Mineralocorticoid deficiency (salt-wasting crisis)	Hyponatremia, hyperkalemia ↓ Aldosterone, ↑ plasma renin	Mineralocorticoid (fludrocortisone) replacement; sodium chloride supplementation
		Ambiguous genitalia in males	Decreased or absent response to hCG in males	Orchidopexy or removal of intraabdominal testes; sex hormone replacement consonant with sex of rearing
		Poor pubertal development or premature ovarian failure in females	↑ FSH, ↑ LH, ↓ estradiol (after puberty)	Estrogen replacement
P450 oxidoreductase deficiency	*POR* 7q11.3	Glucocorticoid deficiency	↓ Cortisol, ↑ ACTH ↑ Pregnenolone, ↑ progesterone	Glucocorticoid (hydrocortisone) replacement
		Ambiguous genitalia in males and females	↑ Serum androgens prenatally, ↓ androgens and estrogens at puberty	Surgical correction of genitals and sex hormone replacement as necessary, consonant with sex of rearing
		Maternal virilization Antley-Bixler syndrome	Decreased ratio of estrogens to androgens	

↓, Decreased; ↑, increased; ↑↑, markedly increased; *ACTH*, adrenocorticotropic hormone; *DHEA*, dehydroepiandrosterone; *DOC*, 11-deoxycorticosterone; *FSH*, follicle-stimulating hormone; *hCG*, human chorionic gonadotropin; *LH*, luteinizing hormone.

BASIC INFORMATION

DEFINITION

The term *conjunctivitis* refers to an inflammation of the conjunctiva resulting from a variety of causes, including allergies and bacterial, viral, and chlamydial infections.

SYNONYMS

"Red eye"
Pink eye
Acute conjunctivitis
Subacute conjunctivitis
Chronic conjunctivitis
Purulent conjunctivitis
Pseudomembranous conjunctivitis
Papillary conjunctivitis
Follicular conjunctivitis
Newborn conjunctivitis

ICD-10CM CODES

H10.9	Unspecified conjunctivitis
B30	Viral conjunctivitis
H10.0	Mucopurulent conjunctivitis
H10.1	Acute atopic conjunctivitis
H10.4	Chronic conjunctivitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 1.6% to 12% in *newborns*
PREVALENCE (IN U.S.):

- Allergic conjunctivitis (Fig. E1), the most common form of ocular allergy, is usually associated with allergic rhinitis and may be seasonal or perennial.
- Bacterial or viral conjunctivitis is often seasonal and can be extremely contagious.

PREDOMINANT AGE: Occurs at *any* age. Most cases in adults are due to viral infection. Children are more prone to develop bacterial conjunctivitis than viral forms.
PEAK INCIDENCE: More common in the spring and fall, when *viral* infections and pollens increase.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Infection and chemosis of conjunctivae with discharge. Gluing of the eyelids and no itching is more indicative of a bacterial cause (Fig. E2).
- Cornea is clear or can be involved (certain bacteria, such as *Neisseria*, can rapidly develop into corneal infection).
- Vision is often normal but can be blurred. Mucus and watering can cause fluctuating vision.
- Fig. E3 illustrates the difference between papillary and follicular conjunctivitis.

ETIOLOGY

- Bacterial: *Haemophilus influenzae, Streptococcus pneumoniae*, and *Moraxella catarrhalis* in children; *Staphylococcus* species in adults. Gram-negative infections are more common in contact lens wearers. *Gonococcal ophthalmia neonatorum* is caused by *Neisseria gonorrhoeae* acquired by exposure of the neonatal conjunctivae to infected cervicovaginal secretions during delivery
- Viral: Most common overall cause of infectious conjunctivitis
- Chlamydial
- Allergic
- Traumatic (chemical or toxin exposure)
- Chronic eyelid inflammation (blepharitis)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute glaucoma (fixed pupil with headache may indicate acute angle closure)
- Corneal lesions
- Acute iritis (with pain and photophobia, blurred vision)
- Episcleritis
- Scleritis (more severe pain, local globe tenderness, and no drainage)
- Canalicular obstruction (eye watering, inflammation near the tear punctum)
- Table 1 compares allergic diseases of the eye; histologic and laboratory manifestations of allergic ocular disease are described in Table 2

WORKUP

- History and physical examination
- Visual acuity and eye examination
- Reports of itching, pain, and visual changes

LABORATORY TESTS

Cultures are useful if not *successfully* treated with antibiotics; initial culture is usually not necessary, since normal conjunctival flora interferes with helpful culture results.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Warm compresses if infective conjunctivitis
- Cold compresses if irritative or allergic conjunctivitis
- Contact lenses should be taken out until an infection is completely resolved. Nondisposable lenses should be cleaned thoroughly as recommended by the manufacturer, and a new lens case should be used. Disposable contact lenses should be thrown away

ACUTE GENERAL Rx

- The majority of cases of bacterial conjunctivitis are self-limiting, and no treatment is necessary in uncomplicated cases.[1]

[1] Azari AA, Barney NP: Conjunctivitis, a systematic review of diagnosis and treatment, *JAMA* 310(16):1721-1729, 2013.

Antibiotic drops (e.g., levofloxacin, ofloxacin, ciprofloxacin, tobramycin, gentamicin ophthalmic solution, 1 or 2 drops q2 to 4h) are indicated for complicated bacterial conjunctivitis, in conjunctivitis caused by gonorrhea or chlamydia, and in bacterial conjunctivitis in contact lens wearers.

- Caution: Be careful with ophthalmic corticosteroid treatment and avoid unless sure of diagnosis; corticosteroids can exacerbate infections and have been associated with increased intraocular pressure and cataract formation.
- An oral antihistamine (e.g., cetirizine, loratadine, desloratadine, or fexofenadine) is effective in relieving itching.
- Mast cell stabilizers (e.g., ketotifen, olopatadine, azelastine bid) are effective for allergic conjunctivitis. Others include Elestat, Optivar, and Patanol.
- Bepotastine, alcaftadine, azelastine, epinastine, and ketotifen are H1-antihistamines and mast cell stabilizers effective for topical treatment of itching associated with allergic conjunctivitis. The topical NSAID ketorolac (0.5%, 1 drop qd) is also useful in allergic conjunctivitis. Table 3 describes topical ophthalmic medications for allergic conjunctivitis.
- Antihistamine/decongestant combinations such as pheniramine/naphazoline (Visine A), available over the counter, are more effective than either agent alone but have a short duration and can result in rebound vasodilatation with prolonged use. Others include Naphcon-A, Albalon-A, and Opcon-A.

CHRONIC Rx

- Depends on cause.
- If allergic, nonsteroidals such as ketorolac and bromfenac ophthalmic solution; mast cell stabilizers such as Patanol and Zaditor (ketotifen) are useful for improving ocular itching in patients with allergic conjunctivitis.
- If an infection, use antibiotic drops (see "Acute General Rx").
- Dry eyes need artificial tears, topical cyclosporine, or lacrimal duct plugs when indicated.
- Chronic and recurrent conjunctivitis often occurs with blepharitis. Daily warm compresses and lid scrub treatment may help relieve symptoms.

DISPOSITION

Follow carefully for the first 2 wk to ensure secondary complications do not occur. Otitis media can develop in 25% of children with *H. influenzae* conjunctivitis. Bacterial keratitis occurs in 30/1000 contact lens wearers.

REFERRAL

To ophthalmologist if symptoms are refractory to initial treatment. Indications for urgent referral are severe eye pain or headache, photophobia, decreased vision, and contact lens use.

TABLE 1 Allergic Diseases of the Eye

Disease	Clinical Parameters	Signs and Symptoms	Differential Diagnosis
Seasonal allergic conjunctivitis (SAC)	Occurs in sensitized individuals Both females and males affected Bilateral involvement Seasonal allergens Self-limiting	Ocular itching Tearing (watery discharge) Chemosis, redness Often associated with rhinitis Not sight-threatening	Infective conjunctivitis Preservative toxicity (any eye drop with preservative) Medicamentosa Dry eye Perennial allergic conjunctivitis Vernal keratoconjunctivitis (VKC) Atopic keratoconjunctivitis (AKC)
Perennial allergic conjunctivitis (PAC)	Occurs in sensitized individuals Both females and males affected Bilateral involvement Year-round allergens Self-limiting	Ocular itching Tearing (watery discharge) Chemosis, redness Often associated with rhinitis Not sight-threatening	Infective conjunctivitis Preservative toxicity Dry eye SAC/AKC/VKC
Atopic keratoconjunctivitis (AKC)	Occurs in sensitized individuals Peak incidence: 20-50 yr of age Both females and males affected Bilateral involvement Seasonal or perennial allergens Atopic dermatitis Chronic symptoms	Severe ocular itching Red, flaking periocular skin Mucoid discharge, photophobia Corneal erosions Scarring of conjunctiva Cataract (anterior subcapsular) Sight-threatening	Contact dermatitis Infective conjunctivitis Blepharitis Pemphigoid VKC/SAC/PAC/GPC
Vernal keratoconjunctivitis (VKC)	Occurs in some sensitized individuals Peak incidence: 3-20 yr of age Males predominate (in 3:1 ratio) Bilateral involvement Warm, dry climate Seasonal/perennial allergens Chronic symptoms	Severe ocular itching Severe photophobia Thick, ropy discharge Cobblestone papillae Corneal ulceration and scarring Sight-threatening	Infective conjunctivitis Blepharitis AKC/SAC/PAC/GPC
Giant papillary conjunctivitis (GPC)	Sensitization not necessary Both females and males affected Bilateral involvement Prosthetic and contact lens exposure Occurs anytime Chronic symptoms Nonseasonal occurrence	Mild ocular itching Mild mucoid discharge Giant papillae Contact lens intolerance Foreign body sensation Protein buildup on contact lens Not sight-threatening	Infective conjunctivitis Preservative toxicity SAC/PAC/AKC/VKC

TABLE 2 Histopathologic and Laboratory Manifestations of Allergic Ocular Disease

Disease	Histopathologic Features	Laboratory Manifestations
Seasonal/perennial allergic conjunctivitis	Mast cell/eosinophil infiltration in conjunctival epithelium and substantia propria Mast cell activation Upregulation of ICAM-1 on epithelial cells	Increased in tears: Specific IgE antibody Histamine Tryptase TNF-α
Atopic keratoconjunctivitis	Increased mast cells, eosinophils in conjunctival epithelium and substantia propria Epithelial cell/goblet cell hypertrophy Increased CD4/CD8 ratio in conjunctival epithelium and substantia propria Increased collagen	Increased specific IgE antibody in tears Depressed cell-mediated immunity Increased IgE antibody and eosinophils in blood Eosinophils found in conjunctival scrapings
Vernal keratoconjunctivitis	Increased mast cells, eosinophils in conjunctival epithelium and substantia propria Eosinophil major basic protein deposition in conjunctiva $CD4^+$ clones from conjunctiva found to have helper function for local production of IgE antibody Increased collagen Increased ICAM-1 on corneal epithelium	Increased specific IgE/IgG antibody in tears Elevated histamine and tryptase in tears Reduced serum histaminase activity Increased serum levels of nerve growth factor and substance P
Giant papillary conjunctivitis	Giant papillae Conjunctival thickening Mast cells in epithelium	No increased histamine in tears Increased tryptase in tears

ICAM-1, Intercellular adhesion molecule 1; *IgE,* immunoglobulin E; *IgG,* immunoglobulin G; *TNF-α,* tumor necrosis factor-α.
From Adkinson NF et al: *Middleton's allergy principles and practice,* ed 8, Philadelphia, 2014, Saunders.

TABLE 3 Topical Ophthalmic Medications for Allergic Conjunctivitis

Drug and Trade Names	Mechanism of Action and Dosing	Cautions and Adverse Events
Azelastine hydrochloride 0.05% Optivar	Antihistamine Children ≥3 yr: 1 gtt bid	Not for treatment of contact lens–related irritation; the preservative may be absorbed by soft contact lenses. Wait at least 10 min after administration before inserting soft contact lenses.
Emedastine difumarate 0.05% Emadine	Antihistamine Children ≥3 yr: 1 gtt qid	Soft contact lenses should not be worn if the eye is red. Wait at least 10 min after administration before inserting soft contact lenses.
Levocabastine hydrochloride 0.05% Livostin	Antihistamine Children ≥12 yr: 1 gtt bid-qid up to 2 wk	Not for use in patients wearing soft contact lenses during treatment.
Pheniramine maleate	Antihistamine/vasoconstrictor	Avoid prolonged use (>3-4 days) to avoid rebound symptoms. Not for use with contact lenses.
0.3% Naphazoline hydrochloride	Children >6 yr: 1-2 gtt qid	
0.025%		
Naphcon-A, Opcon-A		
Cromolyn sodium 4% Crolom, Opticrom	Mast cell stabilizer Children >4 yr: 1-2 gtt q4-6h	Can be used to treat giant papillary conjunctivitis and vernal keratitis. Not for use with contact lenses.
Lodoxamide tromethamine 0.1% Alomide	Mast cell stabilizer Children ≥2 yr: 1-2 gtt qid up to 3 mo	Can be used to treat vernal keratoconjunctivitis. Not for use in patients wearing soft contact lenses during treatment.
Nedocromil sodium 2% Alocril	Mast cell stabilizer Children ≥3 yr: 1-2 gtt bid	Avoid wearing contact lenses while exhibiting the signs and symptoms of allergic conjunctivitis.
Pemirolast potassium 0.1% Alamast	Mast cell stabilizer Children >3 yr: 1-2 gtt qid	Not for treatment of contact lens–related irritation; the preservative may be absorbed by soft contact lenses. Wait at least 10 min after administration before inserting soft contact lenses.
Epinastine hydrochloride 0.05% Elestat	Antihistamine/mast cell stabilizer Children ≥3 yr: 1 gtt bid	Contact lenses should be removed before use. Wait at least 15 min after administration before inserting soft contact lenses. Not for the treatment of contact lens irritation.
Ketotifen fumarate 0.025% Zaditor	Antihistamine/mast cell stabilizer Children ≥3 yr: 1 gtt bid q8-12h	Not for treatment of contact lens–related irritation; the preservative may be absorbed by soft contact lenses. Wait at least 10 min after administration before inserting soft contact lenses.
Olopatadine hydrochloride 0.1%, 0.2%, 0.7% Patanol Pataday Pazeo	Antihistamine/mast cell stabilizer Children ≥3 yr: 1 gtt bid (8 hr apart) Children ≥2 yr: 1 gtt qd	Not for treatment of contact lens–related irritation; the preservative may be absorbed by soft contact lenses. Wait at least 10 min after administration before inserting soft contact lenses.
Alcaftadine, 0.25% Lastacaft	Antihistamine/mast cell stabilizer Children >2 yr: 1 gtt bid q8-12h	Contact lenses should be removed before application; may be inserted after 10 min. Not for the treatment of contact lens irritation.
Bepotastine besilate 1.5% Bepreve	Antihistamine/mast cell stabilizer Children >2 yr: 1 gtt bid q8-12h	Contact lenses should be removed before application, may be inserted after 10 min. Not for the treatment of contact lens irritation.
Ketorolac tromethamine 0.5% Acular	NSAID Children ≥3 yr: 1 gtt qid	Avoid with aspirin or NSAID sensitivity. Use ocular product with caution in patients with complicated ocular surgeries, corneal denervation or epithelial defects, ocular surface diseases (e.g., dry eye syndrome), repeated ocular surgeries within a short period, diabetes mellitus, or rheumatoid arthritis; these patients may be at risk for corneal adverse events that may be sight-threatening. *Do not use while wearing contact lenses.*
Fluorometholone 0.1%, 0.25% suspension (0.1%, 0.25%) and ointment (0.1%) FML, FML Forte, Flarex	Fluorinated corticosteroid Children ≥2 yr, 1 gtt into conjunctival sac of affected eye(s) bid-qid. During initial 24-48 hr, dosage may be increased to 1 gtt q4h. Ointment (~1.3 cm in length) into conjunctival sac of affected eye(s) 1-3 times daily. May be applied q4h during initial 24-48 hr of therapy.	If improvement does not occur after 2 days, patient should be reevaluated. Patient should remove soft contact lenses before administering (contains benzalkonium chloride) and delay reinsertion of lenses for ≥15 min after administration. Close monitoring for development of glaucoma and cataracts.

bid, Two times daily; *gtt,* drops; NSAID, nonsteroidal antiinflammatory drug; *q4-6h,* every 4-6 h; *qd,* every day; *qid,* four times daily.
From Kliegman RM: *Nelson textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

PEARLS & CONSIDERATIONS

COMMENTS

- Red eyes are not simply conjunctivitis when the patient has significant pain or loss of sight. However, it is usually safe to treat pain-free eyes and the normal-seeing red eye with lid hygiene and topical treatment.
- Use caution with patients wearing soft contact lenses, infants, and the elderly.
- Do not use steroids indiscriminately; use only when the diagnosis is certain.
- Bacterial conjunctivitis is generally self-limiting. More than 60% of persons will improve with placebo within 2 to 5 days.

Conjunctivitis (Patient Information)

AUTHOR: **R. Scott Hoffman, MD**

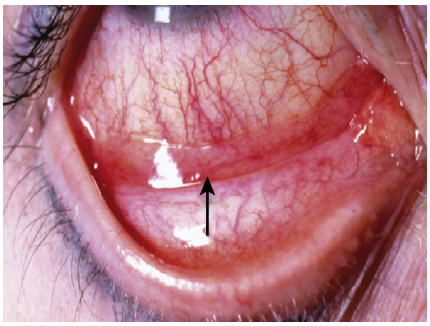

FIG. E1 Allergic conjunctivitis. *Arrow* indicates area of chemosis in the conjunctivitis. (From Adkinson NF Jr et al [eds]: *Middleton's allergy principles and practice,* ed 7, vol 2, Philadelphia, 2008, Mosby.)

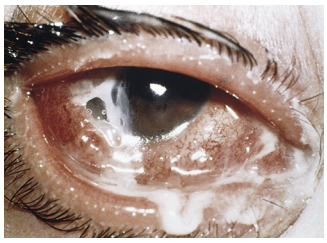

FIG. E2 Bacterial conjunctivitis. Purulent discharge and conjunctiva hyperemia suggest bacterial conjunctivitis. Viral conjunctivitis produces watery discharge, foreign body sensation, preauricular lymphadenopathy, and conjunctival follicles seen on slit lamp examination. (Reproduced with permission from the American Academy of Ophthalmology. From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

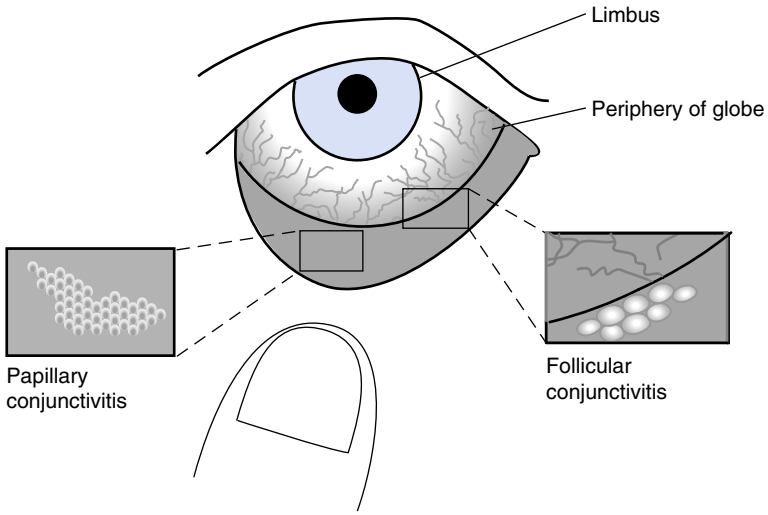

FIG. E3 Conjunctivitis: Papillary versus follicular. The erythema of conjunctivitis (*shaded dark gray*) is most intense on the inside surface of the eyelids (tarsal conjunctiva) and peripherally on the globe (near the fornices), whereas the erythema is less intense centrally near the limbus. In more severe conjunctivitis, the entire conjunctival surface (both tarsal and bulbar) is red. This pattern of erythema contrasts with iritis, which causes more intense erythema centrally around the limbus, a finding called *circumlimbal flush* or *ciliary flush*. In patients with conjunctivitis, the clinician should inspect the everted upper or lower lids, noting whether the inner membrane has its normal smooth surface or instead has small, uneven projections, which are characterized as either *papillae* or *follicles*. In this example, the clinician has used his thumb to gently evert the lower lid for inspection. Papillae *(left bottom)* are contiguous red vascular bumps; the center of each papilla contains a blood vessel. They are red on the surface and pale at the base. Papillae are often so tiny that the conjunctiva acquires a velvety appearance, and only magnification reveals their true nature. Other times, papillae may become large and produce a cobblestone appearance. Follicles *(right bottom)* are discrete 1- to 2-mm-diameter white bumps consisting of aggregates of lymphoid tissue; the center of each is avascular. They are pale on the surface and red at the base. (From McGee S: *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2018, Elsevier.)

Connective Tissue Disease–Associated Vasculitis

BASIC INFORMATION

DEFINITION

Vasculitis is defined by inflammatory leukocytes and subsequent necrosis of blood vessel walls that can eventually lead to tissue ischemia. When vasculitis is associated with a connective tissue disease (CTD), it is defined as a secondary vasculitis. The connective tissue diseases that most commonly cause vasculitis include rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjögren syndrome (SS). Vasculitis rarely occurs in the setting of other connective tissue diseases, including systemic sclerosis (SSc), relapsing polychondritis, primary antiphospholipid syndrome, inflammatory myopathies, and mixed connective tissue disease. Vasculitis is typically classified into large, medium, and small vessel vasculitis. When associated with a connective tissue disease, any type of vasculitis can occur; however, small vessel vasculitis is most common.

SYNONYMS

Connective tissue disorder–associated vasculitis
CTD

ICD-10CM CODE

M35.9 Systemic involvement of connective tissue, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Rheumatoid vasculitis: Estimated to occur in 1% to 5% of patients with RA, with no racial or ethnic predominance. Incidence is decreasing.
- Lupus-associated vasculitis: Estimates of the prevalence range from 11% to 36%.
- Sjögren-associated vasculitis: Cutaneous vasculitis occurs in approximately 10% of patients with primary Sjögren; systemic vasculitis is rare.
- Other CTD: Rare, but well described.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

GENERAL:

- Constitutional symptoms—fatigue, myalgias, weight loss, fever
- Skin manifestations—nail fold lesions (splinter hemorrhages), palpable purpura, leg ulcers, panniculitis, digital gangrene, livedo reticularis, urticaria, Janeway lesions, Osler nodes
- Neurologic manifestations—mononeuritis multiplex, distal symmetric sensorimotor neuropathy, transverse myelitis
- Ocular manifestations—episcleritis, scleritis, ulcerative keratitis
- Cardiac manifestations—arrhythmias, pericarditis, aortitis
- Gastrointestinal manifestations—pancreatitis, peritonitis, colitis
- Pulmonary manifestations—pneumonitis, alveolar hemorrhage
- Renal manifestations—glomerulonephritis

NOTE: Any organ may be involved because vasculitis can disrupt the corresponding vasculature (an example would be kidney injury due to destructive inflammation of the renal vasculature).

MOST COMMON SYNDROMES:

- Rheumatoid vasculitis:
  1. The most common clinical presentation of rheumatoid vasculitis includes skin lesions and peripheral neuropathy.
  2. Although a diagnosis of RA is needed to develop a secondary vasculitis, occasionally the vasculitic symptoms are the first manifestation of RA.
  3. Most patients with rheumatoid vasculitis have long-standing uncontrolled erosive RA, with rheumatoid nodules and high levels of rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP).
  4. The diagnosis of rheumatoid vasculitis is usually confirmed by obtaining a biopsy of the clinically involved organ.
- Lupus-associated vasculitis:
  1. Skin lesions are the most common manifestation.
  2. The most common types of skin lesions are palpable purpura, petechiae, papulonodular lesions, livedo reticularis, panniculitis, and splinter hemorrhages.
- Sjögren-associated vasculitis:
  1. Vasculitis is one of the most common extraglandular manifestations of Sjögren syndrome.
  2. The most common skin lesions are palpable purpura, which most often represents a leukocytoclastic vasculitis.
  3. It can be quite difficult to tell the difference between vasculitis secondary to Sjögren disease and a concomitant primary vasculitis. Sjögren disease has been associated with several other primary vasculitides, including ANCA-associated vasculitis and polyarteritis nodosa. Should also assess for cryoglobulinemia.

ETIOLOGY

The vasculitis usually reflects the pathophysiology of the underlying connective tissue disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection
- Hypercoagulable states (thrombotic thrombocytopenic purpura, hemolytic–uremic syndrome)
- Malignancy (leukemia, lymphoma)
- Primary vasculitides

WORKUP

The diagnosis usually requires multiple modalities, including a full history and physical, as well as laboratory testing, imaging, and sometimes a biopsy of skin or other involved organ. In order to have a connective tissue disease–associated vasculitis, one must meet diagnostic criteria for an underlying connective tissue disease.

LABORATORY TESTS

- Erythrocyte sedimentation rate/c-reactive protein
- CBC with diff. and platelets
- Albumin
- Complement studies
- Blood urea nitrogen and creatinine
- Urinalysis
- Antinuclear antibodies, RF, anti-CCP antibodies
- Double-stranded DNA (dsDNA) (if patient has a history suggesting SLE)
- Antineutrophil cytoplasmic antibodies (ANCA) that include ANCA-specific antibodies (anti-proteinase-3 and antimyeloperoxidase antibodies)

IMAGING AND OTHER STUDIES

- Imaging may be helpful depending on the clinical manifestations of the disease. For instance, in aortitis or renal artery vasculitis, an angiogram, computed tomography angiography, or magnetic resonance angiography may be useful.

- Biopsy of the affected site may be very useful. Skin, nerve, muscle, and kidney biopsies, depending on the affected organ system, will usually help to arrive at a final diagnosis and rule out vasculitis mimics.

Rx TREATMENT

Initial treatment is aimed at the underlying connective tissue disease. Additional immunosuppressive therapy may be needed depending on the severity of the vasculitis.

CHRONIC Rx

May need extended immunosuppressive therapy to prevent relapse

REFERRAL

Rheumatology

PEARLS & CONSIDERATIONS

COMMENTS

Patients with a history of CTD who present with new cutaneous lesions or systemic symptoms should be evaluated for vasculitis. Conversely, in patients who present with vasculitis, consideration should be given to the possibility of underlying CTD.

It is important not to confuse vasculitis with vasculopathy. The latter is a noninflammatory vascular process that is integral to the pathophysiology of some CTDs, such as SLE and SSc.

BASIC INFORMATION

DEFINITION

Decreased stool frequency (fewer than three bowel movements [BM] per wk) with complaints of excessive straining, lower abdominal fullness, hard stools, feeling of incomplete evacuation, commonly associated with hardened feces or another underlying disorder.

Rome IV criteria (see "Diagnosis") are used to classify patients.

ICD-10CM CODES

K59.0	Constipation
K59.00	Unspecified
K59.01	Slow-transit constipation
K59.02	Outlet dysfunction constipation
K59.03	Drug-induced constipation
K59.04	Chronic idiopathic constipation
K59.09	Other constipation
K59.8	Other specified functional intestinal disorders
K59.9	Functional intestinal disorder, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- 12% to 19% of adults all ages
- Chronic constipation increases with age
- 33.5% of adults 60 to 101 yr of age
- Approximately 26% of men and 34% of women >65 have constipation

RISK FACTORS: More prevalent in women, nonwhites, patients with low income, patients older than 60 yr, patients who perform little physical activity, patients with low education level, or those with underlying medical condition predisposing them to constipation (e.g., Parkinson disease)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- A thorough history is paramount for evaluation. The duration of constipation, change in bowel movements, medication history, or any other concurrent medical history is important to inform your diagnosis.
- Clinical presentation varies for every patient, as their personal definition of constipation may differ from medical lexicon.
- Constipation can be accompanied by an increased frequency of liquid stools (overflow diarrhea), typically caused by stool impaction.
- Must rule out alarm features such as hematochezia, weight loss of greater than 10 lbs, a family history of colon cancer or inflammatory bowel disease, anemia, positive fecal occult blood tests, or acute onset of constipation.
- Physical examination must include a digital rectal exam.
- Rectal examination will rule out etiologies that can result in constipation. Pain on examination, asymmetric anal opening, impaired sphincter function, masses, strictures, or the presence and character of stool (soft, hard, impacted) can help determine the etiology.
- Clinical clues to an evacuation disorder are summarized in Box 1.

ETIOLOGY

- Characterized as idiopathic vs. secondary causes of constipation.
- Secondary causes include neurologic, metabolic, or endocrine disturbances; psychiatric disorders; gastrointestinal (GI) malignancies; and medication-induced constipation.
- Types of anorectal dysfunction causing rectal outlet delay in older people are summarized in Table 1.
- Medication-induced constipation is very common; frequent offenders include:
  1. Anticholinergics
  2. Iron supplements
  3. Antacids
  4. Opiates
  5. Antihypertensive medications (especially calcium channel blockers)
  6. Serotonin antagonists
  7. Ganglionic blockers

DIAGNOSIS

BASED ON ROME IV CRITERIA

- Symptoms present for at least 3 mo out of the previous 6 mo.
- Loose stools are rarely present without the use of laxatives.
- Criteria for irritable bowel syndrome (IBS) are not met.
- Presence of two or more of the following specific symptoms:
  1. Straining during more than 25% of defecations
  2. Lumpy or hard stools in more than 25% of defecations
  3. Sensation of incomplete evacuation for more than 25% of defecations
  4. Sensation of anorectal obstruction/blockage for more than 25% of defecations
  5. Manual maneuvers to facilitate more than 25% of defecations (e.g., digital evacuation, support of the pelvic floor)
  6. Fewer than three spontaneous bowel movements per wk
- See Fig. 1 for an algorithmic approach to the diagnosis of constipation.

DIFFERENTIAL DIAGNOSIS

- First delineate between functional constipation vs. secondary causes.
- Secondary causes of constipation include medications, diabetes, hyperparathyroidism, hypothyroidism, lead poisoning, uremia, Parkinson disease, multiple sclerosis, scleroderma, lupus, and malignancy.
- Functional constipation must be differentiated from irritable bowel syndrome (IBS), inflammatory bowel disease (IBD), appendicitis, ileus, and Ogilvie syndrome.

BOX 1 Clinical Clues to an Evacuation Disorder

History

Prolonged straining to expel stool
Assumption of unusual postures on the toilet to facilitate stool expulsion
Support of the perineum, digitation of rectum, or application of pressure to the posterior vaginal wall to facilitate rectal emptying
Inability to expel enema fluid
Constipation after subtotal colectomy for constipation

Rectal Examination (with patient in left lateral position)

Inspection

Anus "pulled" forward during attempts to simulate strain during defecation
Anal verge descends <1 cm or >4 cm (or beyond ischial tuberosities) during attempts to simulate straining at defecation.
The perineum balloons down during straining; rectal mucosa partially prolapses through anal canal.

Palpation

High anal sphincter tone at rest precludes easy entry of the examining finger (in absence of a painful perianal condition [e.g., anal fissure]).
Anal sphincter pressure during voluntary squeeze only minimally higher than anal pressure at rest.
The perineum and examining finger descend <1 cm or >4 cm during simulated straining at defecation.
The puborectalis muscle is tender to palpation through the rectal wall posteriorly, or palpation reproduces pain.
Palpable mucosal prolapse during straining.
"Defect" in anterior wall of the rectum, suggestive of rectocele.

Anorectal Manometry and Balloon Expulsion (with patient in left lateral position)

Elevated resting anal sphincter pressure
Delay in balloon expulsion test (normal values for women <50 yr: 4-75 seconds; normal values for women ≥50 yr of age: 3-15 seconds*

*Noelting J et al: Normal values for high-resolution anorectal manometry in healthy women: effects of age and significance of rectoanal gradient, *Am J Gastroenterol* 107:1530-1536, 2012.

Bharucha AE et al: American Gastroenterological Association technical review on constipation, *Gastroenterology* 2013;144(1):218-238. doi:10.1053/j.gastro.2012.10.028

TABLE 1 Types of Anorectal Dysfunction Causing Rectal Outlet Delay in Older People

	Pathophysiology	Clinical Picture
Rectal dysmotility	Reduced rectal motility and contractions Increased rectal compliance Variable degree of rectal dilation Impaired rectal sensation with blunting of urge to pass stool Over time, increasing rectal distention required to reflexively trigger the defecation mechanism	Rectal hard or soft stool retention on digital examination of which patient may be unaware Chronic rectal distention leads to relaxation of the internal sphincter and fecal soiling One postulated cause is diminished parasympathetic outflow as a result of impaired sacral cord function (e.g., from ischemia or spinal stenosis); may also develop through persistent disregard or suppression of the urge to defecate as a result of dementia, depression, immobility, or painful anorectal conditions
Pelvic floor dyssynergia	Paradoxical contraction or failure to relax the pelvic floor and external anal sphincter muscles during defecation Manometric studies show paradoxical increases in anal canal pressure on straining	Severe and long-standing symptoms of rectal outlet delay Parkinson disease More common in younger women
Irritable bowel syndrome	Increased rectal tone and reduced compliance Lower pain threshold on distending the rectum during anorectal function tests	Usually constipation-predominant in older people Rome criteria symptoms: Abdominal distention or pain relieved by defecation, passage of mucus, and feeling of incomplete emptying

Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

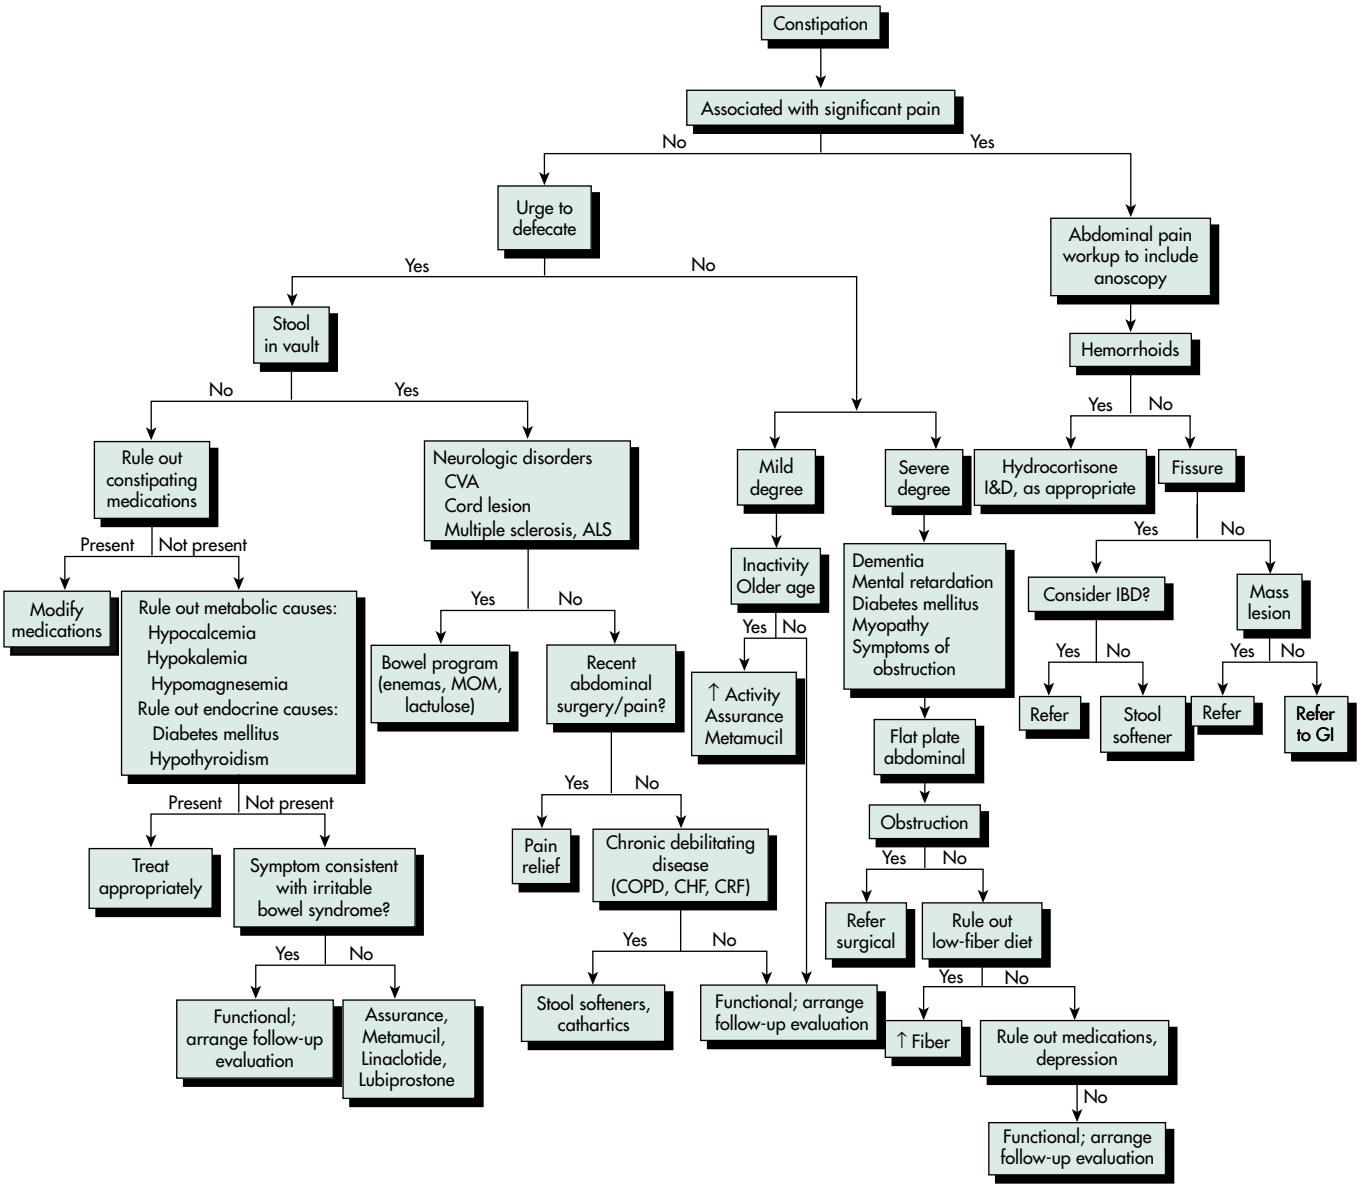

FIG. 1 Algorithmic approach to the diagnosis of constipation. *ALS,* Amyotrophic lateral sclerosis; *CHF,* congestive heart failure; *COPD,* chronic obstructive pulmonary disease; *CRF,* chronic renal failure; *CVA,* cerebrovascular accident; *GI,* gastroenterology; *IBD,* inflammatory bowel disease; *I&D,* incision and drainage; *MOM,* milk of magnesia. (From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, WB Saunders.)

WORKUP

- A thorough history should include presence of alarm signs, dietary habits, list of medications, underlying systemic or neurological disorders, and patient's lifestyle/level of activity.
- Physical examination must include a rectal examination to evaluate for hemorrhoids, stool consistency, melena, hematochezia, rectal prolapse, abnormal rectal tone, or rectocele. The sensitivity and specificity of a digital rectal exam to diagnose dyssynergic defecation are 75% and 87%, respectively.
- Stool impaction can present as diarrhea and is diagnosed with a digital rectal exam and physical/radiologic findings consistent with increased stool burden.

LABORATORY TESTS

Routine laboratory tests are not required to diagnose constipation. However, patients with alarm signs should get a complete blood cell count, basic metabolic panel, thyroid-stimulating hormone, and fecal occult blood test.

IMAGING STUDIES

- Not required but may help rule out secondary causes.
- Plain film x-rays of the abdomen can be used to diagnose stool retention, which can possibly suggest ileus vs. obstruction vs. possible malignancy.
- If infrequent defecation is the major complaint, colon transit studies (via wireless motility capsule study) and whole-gut transit times can be useful, but they are only indicated in patients with chronic constipation that is refractory to laxatives and other conservative measures.
- Defecography is performed when the anorectum has anatomical and functional changes and is thought to contribute to constipation.
- Motility studies include anorectal manometry, colonic manometry, and balloon expulsion.

Rx TREATMENT

After a thorough history and physical examination, combined with the absence of alarm signs, it is appropriate to initiate empiric treatment, including patient education, dietary changes, and fiber therapy without further diagnostic workup. If there is no response, then laxative therapy is indicated.

See Box 2 for a general approach to the treatment of constipation.

NONPHARMACOLOGIC THERAPY

- In patients with pelvic floor dysfunction as the major cause of constipation, biofeedback is a behavioral approach that can be used to correct inappropriate contraction of the pelvic floor muscles and external anal sphincter during defecation.
- Manual disimpaction can be a necessary intervention to remove hard stool in the rectal vault; at times this must be done in the operating room (depending on the volume of impacted stool).
- In patients unresponsive to medical therapy and with favorable manometry studies, subtotal colectomy with ileorectal anastomosis may be considered.

ACUTE GENERAL Rx

- Fiber (dietary or supplemental) is the first-line treatment.
- Laxatives, including bulk-forming, osmotic, and stimulant, are the next therapy to utilize.
  1. Bulk-forming laxatives include psyllium, methylcellulose, wheat dextrin, and polycarbophil.
  2. Osmotic laxatives include polyethylene glycol, lactulose, milk of magnesia, and magnesium citrate.
  3. Stimulant laxatives include bisacodyl, senna, and sodium picosulfate.
- Suppositories and/or enemas should be used if oral therapy is ineffective.
- Many agents can be used in combination if no alarm signs are present.
- Bowel preparation in older people is summarized in Table E3.

CHRONIC Rx

- Many of the agents used in acute constipation also have a role in chronic constipation.
- Be wary of the chronic use of stimulant laxatives, as they can cause colonic epithelial dysfunction.
- Less common, but used for chronic constipation, include:
  1. Linaclotide: Guanylate cyclase-c reactor agonist. It stimulates intestinal fluid secretion and transit.
  2. Plecanatide: Guanylate cyclase-c reactor agonist. It stimulates intestinal fluid secretion and transit.
  3. Lubiprostone: Chloride channel activator that enhances chloride-rich intestinal fluid secretion.
  4. Misoprostol: Prostaglandin analog.
  5. Botulinum toxins: In patients with pelvic floor dysfunction with injection into the puborectalis muscle.
  6. Naldemedine: Opioid receptor antagonist useful for opioid-induced constipation.
  7. Prucalopride: Selective 5-HT4 receptor agonist.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture can be recommended for chronic idiopathic constipation, but the efficacy of this treatment methodology has not been established.

DISPOSITION

- Constipation can be treated in outpatient clinic settings with dietary modifications, medications, and follow-up visits.

BOX 2 General Approach to Treatment of Constipation

For specific agents, dosages, and precautions, see Table 2.

I. Core Program for All Patients

- Adequate intake of fluid and fiber is one key to preventing constipation. Fiber is available primarily from grains and bran cereals. Flatulence, bloating, and cramps are common side effects encountered when bran fiber is introduced.
- Another source of bulk is from synthetic bulk agents (e.g., psyllium). Bulk agents require an adequate amount of fluid intake; otherwise, they may worsen constipation.
- Avoid irritant laxatives as part of a core program, because long-term use may decrease bowel motility. Encourage the patient to exercise and respond promptly to the urge to defecate.

II. Individualized Program-Specific Indications and General Comments

- *Stimulant laxatives (e.g., senna, bisacodyl):* Many believe that long-term use of these agents leads to dependency and habituation, but this is not substantiated. When used appropriately, these medications are not harmful and are very effective. Senna is probably the first-line choice among this class of laxatives.
- *Osmotic laxatives (e.g., polyethylene glycol [PEG], lactulose, milk of magnesia, magnesium citrate):* These agents are most commonly used for colonic preparation before bowel procedures. These agents are safe and well tolerated. PEG has been shown to be slightly more effective than lactulose and causes less bloating and flatus.
- *Lubricants and stool softeners:* Oral mineral oil lubricants and stool softeners are particularly helpful in patients who have acute painful perianal lesions. The softening and coating of the stool can make passage much easier and less painful, preventing constipation. Mineral oil is contraindicated in patients with swallowing problems or in those who are particularly debilitated, to prevent aspiration leading to lipid pneumonia.
- *Suppositories and enemas:* These agents may be helpful in patients who tend to have trouble expelling soft stool from the rectum. Glycerin suppositories may have a soothing effect and be helpful in patients with constipation caused by local, painful perianal lesions. Tapwater enemas are helpful when disimpaction is necessary.

From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, WB Saunders.

TABLE 2 Preparations Commonly Used in the Symptomatic Treatment of Constipation

Medication	Maximal Recommended Dose	Onset of Action	Comments
Bulk Laxatives			Indigestible fiber attracts water, which leads to larger, softer fecal mass.
Psyllium (Metamucil)	Titrate up to 20 g	12-72 hr	Natural fiber that undergoes bacterial degradation, which may contribute to bloating and flatus. Should be taken with plenty of water to avoid intestinal obstruction.
Methylcellulose (Citrucel)	Titrate up to 20 g		Semisynthetic cellulose fiber that is relatively resistant to colonic bacterial degradation.
Polycarbophil (Fibercon)	Titrate up to 20 g		Synthetic fiber of polymer of acrylic acid, resistant to bacterial degradation.
Osmotic Laxatives			Draw water into the intestines along osmotic gradient.
Magnesium or Sodium Salts			
Magnesium hydroxide (Milk of Magnesia)	30-45 ml once daily	1-6 hr	A small percentage of magnesium is absorbed. Use caution in patients. with renal insufficiency and in children.
Magnesium citrate	150-300 ml as needed	3-6 hr	
Sodium phosphate (Fleet Phospho-soda)	20-45 ml with 12 oz of water as needed		Hyperphosphatemia may result if patient has renal insufficiency. Commonly used before colonoscopy.
Poorly Absorbed Sugars			
Lactulose	15-30 ml once or twice a day	24-48 hr	Synthetic disaccharide not absorbed by the small intestine. Gas and bloating common.
Sorbitol	15-30 ml once or twice a day		Poorly absorbed by small intestine.
Polyethylene glycol and electrolytes (GoLYTELY, MiraLax)	17 g two or three times a day	12-24 hr	Organic polymers that are poorly absorbed and not metabolized by bacteria, thus may cause less bloating and cramping. Can be mixed with noncarbonated beverages.
Stimulant Laxatives			Stimulate intestinal motility or secretion.
Senna (Senokot, Ex-Lax)	8-34 mg daily	6-12 hr	Stimulates secretion and motility of small intestine and colon.
Bisacodyl (Dulcolax, Correctol)	5-10 mg daily		
Stool Softeners			Increase water penetration and soften stool.
Docusate sodium (Colace)	100 mg twice a day; some use higher doses	24-48 hr	In many studies, no better than placebo. Not recommended as first-line or solo therapy.
Mineral oil (Fleet Mineral Oil)	5-15 ml orally at night		Provides lubrication for the passage of stool. Long-term use is not recommended. Lipid pneumonia can occur in patients predisposed to aspiration.
Other Agents			
Lubiprostone (Amitiza)	24 μg once or twice per day	1 hr	A chloride channel activator. FDA-approved for treatment of chronic idiopathic constipation in adults. Adverse effects: Headache, nausea, diarrhea.
Methylnaltrexone (Relistor)	8-12 mg SQ		Used in refractory opioid-induced constipation.
Linaclotide (Linzess)	145 mcg daily 30 min prior to meals	2-6 hr	Peptide agonist of the guanylate cyclase 2C. It increases smooth muscle contractions. Useful in IBS with constipation.
Plecanatide (Trulance)	3 mg once/day	<24 hr	Peptide agonist of the guanylate cyclase 2C. It increases smooth muscle contractions. Useful in IBS with constipation.
Naldemedine (Symproic)	0.2 mg once/day	2 h	Opioid receptor antagonist.

FDA, U.S. Food and Drug Administration; *IBS,* irritable bowel syndrome; *SQ,* subcutaneously.
Modified from Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, WB Saunders.

- Occasionally, constipation must be addressed in the inpatient setting.

REFERRAL

- A referral to a gastroenterologist is not typically necessary for routine cases but is essential for refractory patients or those who may need a colonoscopy, sigmoidoscopy, or manometric studies.
- A referral to a surgeon may be required in patients with large volumes of impacted stool (requiring disimpaction under anesthesia), megacolon, megarectum, or chronic slow transit constipation that is nonresponsive to medical treatment.

PEARLS & CONSIDERATIONS

- The presence of weight loss, rectal bleeding, or anemia with constipation mandates a colonoscopy or flexible sigmoidoscopy.
- A thorough history and physical examination including digital rectal examination is important in diagnosis and cause of constipation.
- History that includes a survey of the patient's diet, medications, and psychosocial issues is key to the successful treatment of constipation.
- Key components in patient education are summarized in Table E4.

AUTHORS: **Curtis Lee Lowery III, MD, PhD,** and **Mark F. Brady, MD, MPH, MMSc**

TABLE E3 Bowel Preparation in Older People

- Older age, constipation, reported laxative use, tricyclic antidepressants, stroke, diabetes, and dementia are associated with inadequate preparation and thus takes longer to instrument the cecum.
- Even in those who take 75% to 100% of their prescribed treatment, bowel preparation is satisfactory in only 50%.

Guidance

- Give regular laxatives (e.g., Movicol two sachets daily) and enemas or suppositories for at least 1 wk before the procedure, with a longer run-up period in patients known to have constipation and in those with comorbidities such as diabetes.
- Individualize the cathartic regimen (e.g., 1 to 2 L of GoLYTELY daily over 2 to 3 days in those unable to drink 4 L, or use of alternative preparations such as sodium picosulfate).
- Identify potential nonadherence. ("Can the patient drink 4 L of GoLYTELY in 24 hours?")
- Preempt unpleasant side effects. ("Will the patient be able to reach the toilet in time to avoid fecal leakage?")
- Use oral phospho soda with caution because administration in older people increases serum phosphate, even in patients with normal creatinine clearance.
- Consider preprocedure plain abdominal x-ray for evaluation of persisting fecal loading.
- Where possible, give clear fluid diet before administration of bowel preparation.

Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

TABLE E4 Patient Education

Toilet Habits and Positioning

- Do not delay having a bowel movement when you feel the urge.
- Put aside a particular time each day (we would advise after breakfast) when you can sit on the toilet without being in a hurry.
- A relaxed attitude to bowel evacuation will help, especially if you have problems with straining or a feeling of anal blockage.
- If straining is a problem, place a footstool under your feet while sitting on the toilet because this increases the ability of your abdominal muscles to help evacuation of stool.

Abdominal Massage

- Lie on the bed with pillows under your head and shoulders.
- Bend your knees, and place a pillow underneath them for support.
- Cover your abdomen with a light sheet.
- Massage your abdomen with firm but gentle circular movements, starting at the right side and working across to the left side.
- Continue the massage for about 10 min.
- This massage should be a pleasant experience; if you feel any discomfort, then stop.

Diet

- To help prevent constipation, you should eat more of the food from list A and less of the food from list B. Food in list A tends to make the stool softer and easier to pass because it is high in fiber. Food in list B tends to make the stool harder because it binds together the contents of the bowel.
- List A: Fresh fruit, prunes and other dried fruit, whole meal bread, bran cereals and porridge, salad, cooked vegetables (with skin where possible), beans, lentils.
- List B: Milk, hard cheese, yogurt, white bread or crackers, refined cereals, cakes, pancakes, noodles, white rice, chocolate, creamed soups.
- You should increase your fiber intake gradually because sudden change in fiber content may cause temporary bloating and irregularity. It is important to eat the food that contains fiber all through the day and not just at one meal such as breakfast.
- Increase the amount of fluid that you drink gradually up to 8 to 10 glasses a day. Try to drink more water, fruit juices, and carbonated drinks.

Sphincter Strengthening

Learning to Do Your Exercises

- Sit in a comfortable position with your knees slightly apart. Now imagine that you are trying to stop yourself passing wind from the bowel. To do this, you must squeeze the muscle around the back passage. Try squeezing and lifting that muscle as tightly as you can. You should be able to feel the muscle move. Your buttocks, abdomen, and legs should not move at all. You should be aware of the skin around the back passage tightening and being pulled up and away from your chair. Really try to feel this. You are now exercising your anal sphincter muscles. (You do not need to hold your breath when you tighten the muscles!)

Practicing Your Exercises

- Tighten and pull up the anal sphincter muscles as tightly as you can. Hold tightened for at least 5 seconds and then relax for at least 10 seconds.
- Repeat this exercise at least five times. This will work on the strength of your muscles.
- Next, pull the muscles to about half of their maximum squeeze. See how long you can hold this for. Then relax for at least 10 seconds.
- Repeat at least five times. This will work on the endurance, or staying power, of your muscles.
- Pull up the muscles as quickly and tightly as you can and then relax and then pull up again. See how many times you can do this before you get tired. Try for at least 5 quick pull-ups. Try this quick pull-up exercise at least 10 times each day.
- Do all these exercises as hard as you can and at least five times a day. As the muscles get stronger, you will find that you can do more pull-ups each time without the muscle getting tired.
- It takes time for exercises to make muscle stronger. You may need to exercise regularly for several months before the muscles gain their full strength.

Instructions for Using Suppositories

- These may be inserted into your rectum (back passage) by your nurse or caregiver or yourself if you are physically able to do it.
- If necessary, go to the toilet and empty your bowels if you can.
- Wash your hands.
- Remove any foil or wrapping from the suppository.
- Either lie on your side with your lower leg straight and your upper leg bent toward your waist or squat.
- Gently but firmly insert the suppository, narrow end first, into the rectum using a finger. Push far enough (about 1 inch) so that it does not come out again.
- You may find your body wanting to push out the suppository. Close your legs and keep still for a few minutes.
- Try not to empty your bowels for at least 10 to 20 min.

Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

BASIC INFORMATION

DEFINITION

Contact dermatitis is an acute or chronic skin inflammation resulting from exposure to substances in the environment. It can be subdivided into "irritant" contact dermatitis (nonimmunologic physical and chemical alteration of the epidermis) and "allergic" contact dermatitis (delayed hypersensitivity reaction).

SYNONYMS

Irritant contact dermatitis
Allergic contact dermatitis

ICD-10CM CODES

L23	Allergic contact dermatitis
L23.0	Allergic contact dermatitis due to metals
L23.1	Allergic contact dermatitis due to adhesives
L23.2	Allergic contact dermatitis due to cosmetics
L23.3	Allergic contact dermatitis due to drugs in contact with skin
L23.4	Allergic contact dermatitis due to dyes
L23.5	Allergic contact dermatitis due to other chemical products
L25.9	Unspecified contact dermatitis, unspecified cause

EPIDEMIOLOGY & DEMOGRAPHICS

- 20% of all cases of dermatitis in children are caused by allergic contact dermatitis.
- Rhus dermatitis (poison ivy, poison oak, and poison sumac) is responsible for most cases of contact dermatitis.
- Frequent causes of irritant contact dermatitis are soaps, detergents, eye drops (Fig. E1), and organic solvents.
- Chemical irritants (e.g., cutting fluids used in machining, solvents) account for most cases of irritant contact dermatitis. Occupational skin diseases are second only to traumatic injuries as the most common types of occupational disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Clinical presentation varies with the responsible agent and affected area of skin.

IRRITANT CONTACT DERMATITIS:

- Mild exposure may result in dryness, erythema, and fissuring of the affected area (e.g., hand involvement in irritant dermatitis caused by exposure to soap [Fig. E2], genital area involvement in irritant dermatitis caused by prolonged exposure to wet diapers).
- Eczematous inflammation may result from chronic exposure.

ALLERGIC CONTACT DERMATITIS:

- Poison ivy dermatitis can present with vesicles and blisters; linear lesions (as a result of dragging of the resins over the surface of the skin by scratching) are a classic presentation.
- The pattern of lesions is asymmetric; itching, burning, and stinging may be present.
- The involved areas are erythematous, warm to touch, swollen, and may be confused with cellulitis.

ETIOLOGY

- Irritant contact dermatitis: Cement (construction workers), rubber, ragweed, malathion (farmers), orange and lemon peels (chefs, bartenders), hair tints, shampoos (beauticians), rubber gloves (medical, surgical personnel)
- Allergic contact dermatitis: Poison ivy, poison oak, poison sumac, rubber (shoe dermatitis), nickel (jewelry), balsam of Peru (hand and face dermatitis), neomycin, formaldehyde (cosmetics)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Impetigo
- Lichen simplex chronicus
- Atopic dermatitis
- Nummular eczema, dyshidrotic eczema
- Seborrheic dermatitis
- Inverse psoriasis, palmoplantar psoriasis
- Scabies
- Tinea pedis

WORKUP

- Medical history: Gradual onset versus rapid onset, number of exposures, clinical presentation, occupational history.
- Physical examination: Contact dermatitis in the neck may be caused by necklaces, perfumes (Fig. E3), aftershave lotion. Involvement of the axillae is often secondary to deodorants, clothing. Face involvement can occur with cosmetics, airborne allergens, aftershave lotion.

LABORATORY TESTS

- Patch testing has a sensitivity and specificity of 70% to 80%. It is useful to confirm the diagnosis of contact dermatitis; it is indicated only when inflammation persists despite appropriate topical therapy and avoidance of suspected causative agent; patch testing should not be used for irritant contact dermatitis because this is a nonimmunologic-mediated inflammatory reaction.
- Dermoscopy and microscopy when suspecting scabies and mites.
- A potassium hydroxide (KOH) preparation may be useful if suspecting tinea or Candida infection.

TREATMENT

NONPHARMACOLOGIC THERAPY

Avoidance of suspected allergens (e.g., use of plain petrolatum instead of topical antibiotics for clean wounds)

ACUTE GENERAL Rx

- Removal of the irritant substance by washing the skin with plain water or mild soap within 15 min of exposure is helpful in patients with poison ivy, poison oak, or poison sumac dermatitis.
- Cold or cool water compresses for 20 to 30 min 5 to 6 times a day for the initial 72 hr are effective during the acute blistering stage.
- Topical steroids (clobetasol 0.05%, triamcinolone 0.1%) are effective for acute localized allergic contact dermatitis lesions. Lower-potency topical steroids are preferred on face, anogenital regions, and flexural surfaces to minimize risk of skin atrophy. Oral corticosteroids (e.g., prednisone 20 mg bid for 6 to 10 days) are generally reserved for severe, widespread dermatitis.

FIG. E1 Contact dermatitis of the periocular skin. The distribution in this patient is common for the area involved with the use of topically applied eye drops and ointment. (From Adkinson NF et al: *Middleton's allergy principles and practice,* ed 8, Philadelphia, 2014, Saunders.)

FIG. E2 Hand dermatitis from a cleanser. The doctor should always consider allergic contact dermatitis in a patient presenting with an eczematous eruption. The hands are a common site for both allergic and irritant contact dermatitis, because they come into contact with so many things. This patient was allergic to an ingredient in the cleanser used at work. (From White GM, Cox NH [eds]: *Diseases of the skin: a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

FIG. E3 Perfume and medicament allergy. Multiple allergies are often found. This patient developed a reaction first to a perfume and then to a topical medication applied to soothe the initial rash. (From White GM, Cox NH [eds]: *Diseases of the skin: a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

- IM steroids (e.g., Kenalog) are used for severe reactions and in patients requiring oral corticosteroids but unable to tolerate PO.
- Oral antihistamines (e.g., hydroxyzine 25 mg q6h) will control pruritus, especially at night; calamine lotion is also useful for pruritus; however, it can lead to excessive drying.
- Colloidal oatmeal (Aveeno) baths can also provide symptomatic relief.
- Patients with mild to moderate erythema may respond to topical steroid gels or creams.
- Patients with shoe allergy should change their socks at least once a day; use of aluminum chloride hexahydrate in a 20% solution (Drysol) qhs will also help control perspiration.
- Use hypoallergenic surgical gloves in patients with rubber and surgical glove allergy.

DISPOSITION

Allergic contact dermatitis generally resolves within 2 to 4 wk if reexposure to allergen is prevented.

REFERRAL

For patch testing in selected patients, see "Laboratory Tests."

PEARLS & CONSIDERATIONS

COMMENTS

Commercially available corticosteroid dose packs should be avoided, because they generally provide an inadequate amount of medication.

BASIC INFORMATION

DEFINITION

Contraception refers to the various modalities that a sexually active couple uses to prevent pregnancy. These options can be either medical or nonmedical and used by men or women or both. There are numerous options, and this chapter should not be considered to be fully comprehensive of every option. The options are as follows:

- No contraception (unprotected intercourse); failure rate 85% both typical use and perfect use
- Abstinence: Failure rate 0%
- Withdrawal: Failure rate with perfect use, 4%; with typical use, 19%
- Rhythm method (natural family planning)
  1. Failure rate with perfect use, 1% to 9%; with typical use, 20%
  2. Lactation amenorrhea method: Effective in fully breastfeeding women, especially 70 to 100 days after delivery; depends on number of feedings per day. Requires exclusive breastfeeding, amenorrhea, and <6 mo postpartum. There is a 0.5% to 2.0% failure rate in the first 6 mo after delivery
- Barriers
  1. Male condom: Failure rate with perfect use, 3%; with typical use, 12%
  2. Female condom: Failure rate with perfect use, 5.1%; with typical use, 12.4%; FDA labeling states 25% failure rate
  3. Diaphragm and cervical cap: Failure rate 5% to 9% in nulliparous women, 20% in multiparous women
  4. Spermicides (aerosols, foam, jellies, creams, tabs): Failure rate with perfect use, 3%; with typical use, 21%
- Oral contraceptives
  1. Failure rate with perfect use, <1%; with typical use, 3%
  2. Come in combinations of estrogen/progestin or as progestin only
  3. Mini pill (progesterone only pill)
     a. Failure rate with typical use, 1.1% to 13.2%
     b. With perfect use, 5 pregnancies per 1000 women
     c. Requires precise timing of daily use for effectiveness
- Hormonal implants and injectables
  1. Nexplanon (etonogestrel) single rod subdermal implant: Failure rate of 0.05%
  2. Depo-Provera: Failure rate 0.3% in first yr of use
  3. Jadelle (levonorgestrel) two rod subdermal implant, not available in the U.S.
- Emergency postcoital contraception
  1. Decreases pregnancy rate by 75% or more with women treated within 72 hrs of coitus
  2. Progestin-only method: 1.5 mg levonorgestrel single dose or 0.75 mg given 12 hrs apart (2.2% pregnancy rate)
  3. Selective progesterone receptor modulator: 30 mg Ulipristal single dose is more effective than levonorgestrel (1.4% pregnancy rate)
  4. Copper IUD: Can be inserted up to 5 days after ovulation and results in the lowest pregnancy rate (0.1%)
- Intrauterine device (IUD)
  1. Copper T (30-A): Failure rate with perfect use, 0.6%; with typical use, 0.8%
  2. Levonorgestrel (LNG-20) IUD (Mirena)
     a) 1-yr failure rate, 0.2%
     b) 5-yr cumulative failure rate, 0.7%
- Female sterilization (tubal ligation): Failure rate with perfect use, 0.2%; with typical use, 3%
- Male sterilization (vasectomy): Failure rate of 0.1% in first yr
- Vaginal ring (NuvaRing): Failure rate pearl index 0.77
- Contraceptive patch (Ortho Evra): Failure rate 0.4% to 0.7%

DIAGNOSIS

WORKUP

- To help facilitate method selection for the patient, we recommend obtaining the below information and consulting with CDC Medical Eligibility Criteria.
  1. Thorough medical history
  2. Thorough surgical history
  3. Obstetric history (was fertility desired with conception?)
  4. Gynecologic history, including:
     a. History of previous sexually transmitted diseases
     b. Previous difficulties with contraception
     c. Frequency of intercourse
  5. Family history
- Table E1 summarizes when to start using contraceptive methods.
- Examinations and tests needed before initiation of contraceptive methods described in Table 2.
- Recommendations for routine follow-up after contraceptive initiation summarized in Table E3.

LABORATORY TESTS

- Pap smear should be done as routine and is not required prior to initiation of contraception
- *Chlamydia* and *Gonorrhea* screening when appropriate
- Pregnancy test if suspected pregnancy
- Lipid profile if family history of premature vascular event

TREATMENT

NONPHARMACOLOGIC THERAPY

- Male condoms
  1. 95% latex (rubber), 5% polyurethane, or natural membrane (lamb's intestine does not block transmission of sexually transmitted infections)
  2. Proper use: Place on an erect penis and leave ½-inch empty space at the tip of the condom; use with non–oil-based lubricants
  3. Effectiveness increased when used with spermicides
  4. Main advantage: Condoms are the only method shown to reduce HIV transmission
- Female condoms
  1. Composed of polyurethane, with one end open and one end closed
  2. Proper use: Place closed end over cervix, open end hanging out of vagina to cover penis and scrotum
  3. Highly effective against HIV
- Spermicides
  1. Types: Nonoxynol, octoxynol
  2. Forms: Jellies, creams, foams, suppositories, tablets, soluble films
  3. Proper use: Put in immediately before intercourse; may be used with other barrier methods
- Diaphragm and cervical cap
  1. Must be fitted by practitioner, used with contraceptive gels, and refitted with weight gain or loss of 4.5 kg. Must also be refitted after pregnancy.
  2. Diaphragm sizes: 50 to 105 mm; cervical cap sizes 26, 28, and 30 mm.
  3. The correct fit allows the woman to remain ambulatory without feeling the device.
  4. Proper use of diaphragm: Put in immediately before intercourse and keep in for 6 hr after intercourse; must not remain in the vagina for longer than 24 hr.
  5. Proper use of cervical cap: Fit over the cervix exactly; must not remain in place for longer than 48 hr.
- Lactation amenorrhea method
  1. Requires exclusive breastfeeding, amenorrhea, and within 6 mo postpartum. If patient begins supplementing with

TABLE 2 Examinations and Tests Needed before Initiation of Contraceptive Methods

BMI, Body mass index; *CDC*, Centers for Disease Control and Prevention; *CHC*, combined hormonal contraceptive; *Cu-IUD*, copper-containing intrauterine device; *HIV*, human immunodeficiency virus; *LNG-IUD*, levonorgestrel-releasing intrauterine device; *POP*, progestin-only pill; *STD*, sexually transmitted disease; *U.S. MEC*, U.S. Medical Eligibility Criteria for Contraceptive Use.

*In instances in which blood pressure cannot be measured by a provider, blood pressure measured in other settings can be reported by the woman to her provider.

†Weight (BMI) measurement is not needed to determine medical eligibility for any methods of contraception because all methods can be used (U.S. MEC 1) or generally can be used (U.S. MEC 2) among obese women. However, measuring weight and calculating BMI at baseline might be helpful for monitoring any changes and counseling women who might be concerned about weight change perceived to be associated with their contraceptive method.

‡A bimanual examination (not cervical inspection) is needed for diaphragm fitting.

¶Most women do not require additional STD screening at the time of IUD insertion. If a woman with risk factors for STDs has not been screened for gonorrhea and chlamydia according to CDC's *STD Treatment Guidelines* (www.cdc.gov/std/treatment), screening can be performed at the time of IUD insertion, and insertion should not be delayed. Women with current purulent cervicitis or chlamydial infection or gonococcal infection should not undergo IUD insertion (U.S. MEC 4).

From Curtis KM et al: U.S. selected practice recommendations for contraceptive use, 2016, *MMWR Recomm Rep* 65(4):1-66, 2016.

formula or has any vaginal bleeding, should counsel patient to use backup birth control as she cannot depend on this method of contraception.
2. Not a common practice in the U.S.

- Withdrawal
  1. Withdrawal of the penis from the vagina before ejaculation
  2. Depends on self-control, but there is a high typical use failure rate
- Rhythm method
  1. Symptothermal type: Mucus method and ovulation pain combined with basal body temperature
  2. Ovulation (Billings method): Takes into account mucus quality
  3. Basal body temperature method: Uses biphasic temperature chart
  4. Depends on awareness of physiology of male and female reproductive tracts
     a. Sperm viable in vagina for 2 to 7 days
     b. Ovum lifespan 24 hr
- Sterilization
  1. Male
     a. Vasectomy to interrupt vas deferens and block passage of sperm to seminal ejaculate
     b. Scalpel and nonscalpel techniques available
     c. More easily performed procedure than female sterilization and does not require general anesthesia
  2. Female
     a. Leading method of birth control in U.S. in women older than 30 yr
     b. Interrupts fallopian tubes, blocking passage of ovum proximally and sperm distally through tube
     c. Methods: Bilateral salpingectomy, tubal ligation via removal of segment of fallopian tube, fulguration, application of clips (Filshie, Hulka) or band (Falope Ring)
     d. Essure-tubal occlusion through hysteroscopic placement of micro-inserts into the fallopian tubes. Has been removed from the market

ACUTE GENERAL Rx

- Combination oral contraceptives
  1. Standard administration: Taken daily for 21 days, pill-free interval of 7 days.
  2. Alternative regimen: Extended or continuous administration of active pills.
  3. Less than 50 mcg ethinyl estradiol in most common combination oral contraceptives; progestins most commonly used in combination pills are norethindrone, levonorgestrel, norgestrel, norethindrone acetate, ethynodiol diacetate, norgestimate, or desogestrel.
  4. Triphasic combination oral contraceptives (give varying doses of progestin and estrogens throughout cycle), monophasic oral contraceptives (offer same dose of progestin and estrogen throughout cycle), Estrophasic pill (constant progesterone with variation of estrogen throughout the cycle).
  5. If pill taken with antibiotics, efficacy affected by inadequate gastrointestinal absorption in most cases; only rifampin truly reduces pill's effectiveness.
  6. Increased body weight decreases effectiveness.
  7. Table E4 describes oral contraceptive formulations available in the U.S. Guidelines for use of combination estrogen-progestin contraceptives in women 35 yr of age and older are described in Table E5.
  8. Fig. E1 describes recommended actions after late or missed combined oral contraceptives.
  9. Recommended actions after vomiting or diarrhea while using combined oral contraceptives are described in Fig. E2.
- Mini pill
  1. Progestin only; taken without a break
  2. May cause irregular bleeding because of the lack of estrogen effect on the lining of the uterus
  3. Table E6 provides a summary and recommendations for progestin-only oral contraceptive use
- Hormonal implants and injectables
  1. Nexplanon
     a. Single etonogestrel-secreting device that is inserted underneath the skin
     b. The most effective contraceptive available
     c. Approved by FDA in 2006 and effective over 3-yr period
  2. Depo-Provera
     a. Medroxyprogesterone acetate given every 3 mo in IM injection form
     b. Major side effect: Irregular bleeding

   c. Fertility return possibly delayed up to 1 yr or longer after last injection
   d. Table E7 provides a summary and recommendations for depot medroxyprogesterone acetate (DMPA) use
- Postcoital emergency contraception
  1. Done on emergency basis, usually as a result of noncompliance with birth control or failure of birth control (e.g., condom breakage) at the time of ovulation
  2. Methods:
     a. Hormonal methods:
        (1) Levonorgestrel is available either as two 0.75 mg tablets taken 12 hr apart (next choice) or as a 1.5 mg tablet taken once (Plan B, one step). It is indicated for emergency contraception to be used within 72 hr after unexpected intercourse. It can be obtained OTC by women >15 yr of age and by prescription by younger patients.
        (2) Ulipristal (ELLA) is a progesterone-receptor agonist/antagonist available by prescription only. It is a 30-mg, single-dose tablet and can be taken up to 5 days after unexpected intercourse.
        (3) Copper IUD insertion within 5 days of coitus.
- IUD
  1. Device inserted into uterus to prevent sperm and ovum from uniting in fallopian tube
  2. Types available in the U.S.:
     a. ParaGard (Copper T/30-A): A polyethylene T wrapped with a fine copper wire effective for 10 yr
     b. Mirena Levonorgestrel Intrauterine System: A T-shaped system with a chamber that contains levonorgestrel. Releases 20 mcg/day. Approved for 5 yr
     c. Skyla: Smaller and lowest dose of levonorgestrel. Releases 14 mcg/day. Approved for 3 yr
     d. Liletta: Most similar to Mirena, but less expensive. Releases 18.6 mcg/day. Recently approved for 6 yr
     e. Kyleena: Another 5-yr levonorgestrel system. Releases 19.5 mcg/day
- Vaginal ring (NuvaRing)
  1. Provides daily dose of 120 mcg of etonogestrel and 15 mcg ethinyl estradiol
  2. Stays in vagina 3 wk and is removed the fourth for a contraceptive-free interval analogous to the placebo pills in oral contraceptive pills
  3. Increased body weight decreases effectiveness
  4. Delivers lower total dose of estrogen than the combination oral contraceptive, but may have higher risk of DVT
  5. Recommended actions after delayed insertion or reinsertion with combined vaginal ring are described in Fig. E3
- Contraceptive patch
  1. Releases a progestin and estrogen (ethinyl estradiol)
  2. Each patch contains 6 mg norelgestromin and delivers an estimated continuous systemic dose of 150 mcg norelgestromin and 15 mcg of ethinyl estradiol daily
  3. Worn 3 out of 4 wk
  4. Increased body weight decreases effectiveness
  5. Concern for increased risk of thromboembolic events
  6. Ortha Evra brand discontinued; Xulane (generic) available in the U.S.
  7. Recommended actions after delayed application or detachment with combined hormonal patch are described in Fig. E4

CHRONIC Rx

- With all the previously mentioned types of birth control, patient is followed up at least yearly, or as necessary, if problems arise.
- Full history, physical examination, and Pap test (per guidelines), including cultures when needed, are performed yearly.
- Patients with medical problems are followed up approximately every 6 mo when taking hormonal therapy.

DISPOSITION

- Follow yearly or more frequently according to patient's side effects.
- Tailor birth control to patient according to different needs or side effects present at different times in life. Effective counseling also requires an understanding of a woman's preference and medical risks, benefits, side effects, and contraindications of each contraceptive method.

COMMENTS

- With hormonal contraception, if neurologic or cardiac symptoms arise, stop method immediately, evaluate, and refer to internist when appropriate.
- The effectiveness of long-acting reversible contraception (IUDs and implants) is superior to that of contraceptive pills, patch, or ring and is not altered in adolescents and young women.
- Management of women with bleeding irregularities while using contraception is described in Fig. E5.

TABLE E5 World Health Organization (WHO) and American College of Obstetrics and Gynecology (ACOG) Guidelines Regarding Use of Combination Estrogen-Progestin Contraceptives (Oral Contraception, Ring, and Patch) in Women 35 Yr of Age and Older

Variable	ACOG Guidelines	WHO Guidelines
Obesity	Progestin-only or intrauterine contraception* may be safer	Benefit usually outweighs risks†
Smoker	Progestin-only or intrauterine contraception* should be used	Risk unacceptable
Hypertension	Progestin-only or intrauterine contraception* should be used	Risk unacceptable
Diabetes	Progestin-only or intrauterine contraception* should be used	Risk unacceptable
Migraine	Progestin-only or intrauterine contraception* should be used	Risk unacceptable
None of the above risk factors	Healthy, nonsmoking women doing well on a combination contraceptive can continue their method until age 50-55 yr after weighing the risks and benefits.	For women ≥40 yr of age, the risk of cardiovascular disease increases with age and also may increase with use of combined hormonal contraceptives. In the absence of other adverse clinical conditions, combined hormonal contraceptives may be used until menopause.

*Generic versions available.
†Chewable tablets.
EE, Ethinyl estradiol.

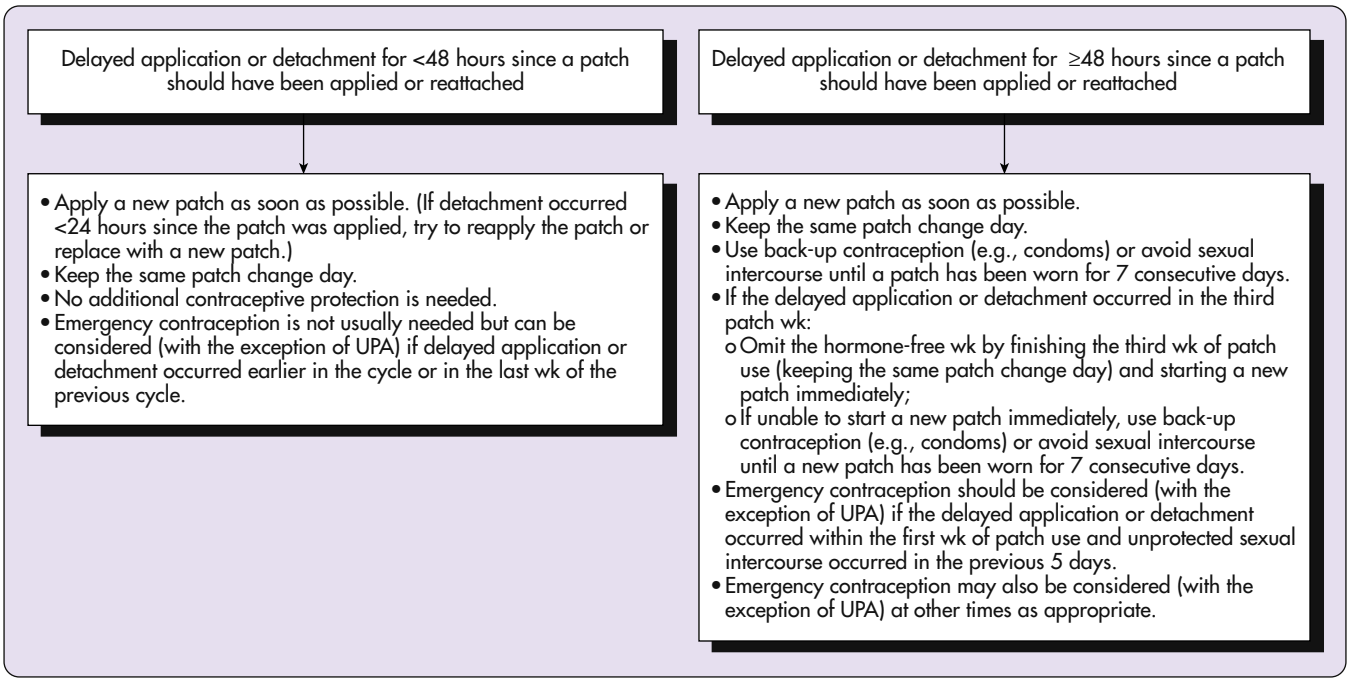
Abbreviation: UPA = ulipristal acetate.

FIG. E1 Recommended actions after late or missed combined oral contraceptives. (From Curtis KM et al: U.S. selected practice recommendations for contraceptive use, 2016, *MMWR Recomm Rep* 65(4):1-66, 2016.)



Abbreviation: UPA = ulipristal acetate.
*If detachment takes place but the woman is unsure when the detachment occurred, consider the patch to have been detached for ≥48 hours since a patch should have been applied or reattached.

FIG. E2 Recommended actions after delayed application or detachment* with combined hormonal patch. (From Curtis KM et al: U.S. selected practice recommendations for contraceptive use, 2016, *MMWR Recomm Rep* 65(4):1-66, 2016.)

TABLE E6 Summary and Recommendations for Progestin-Only Oral Contraceptive Use

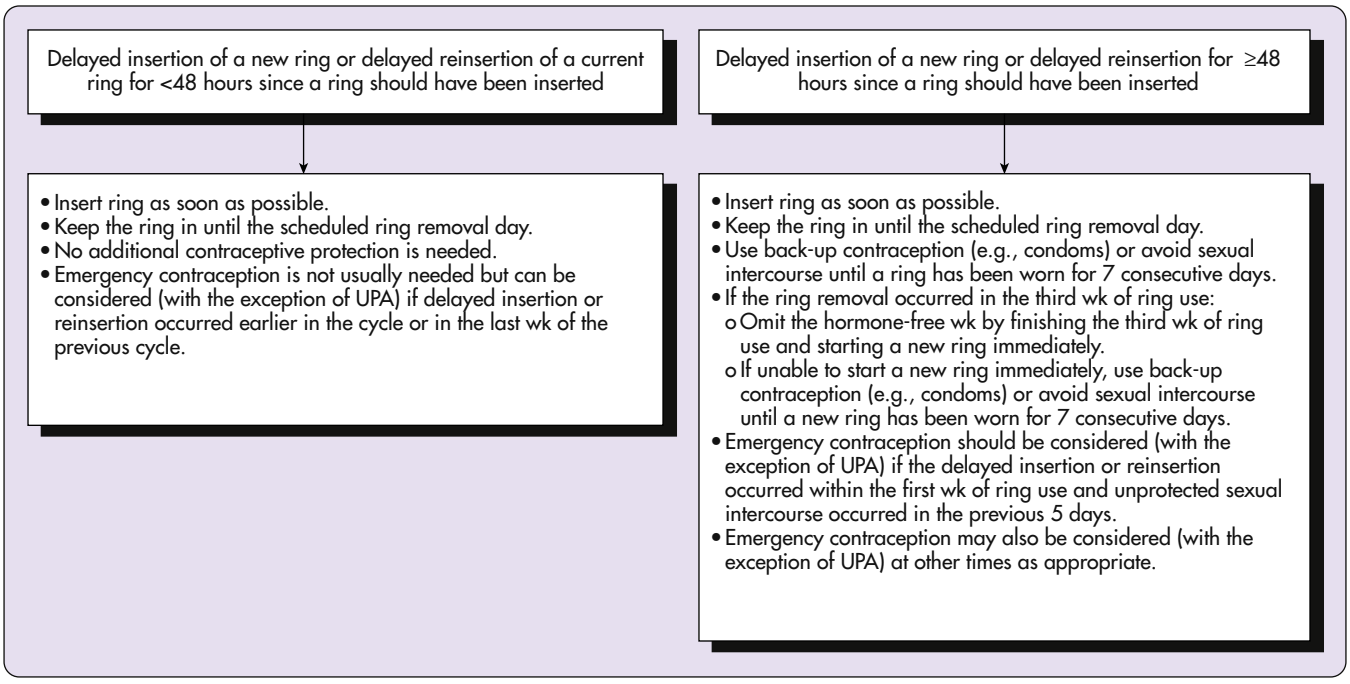
1. Progestin-only contraception is an option for women in whom an estrogen-containing contraceptive is either contraindicated or causes additional health concerns.
2. Ovulation is not consistently suppressed; the main contraceptive actions of progestin-only oral contraception are effects on cervical mucus and the endometrium.
3. The typical user failure rate with progestin-only oral contraception is estimated to be >8%. Women choosing progestin-only oral contraception are often subfertile as a result of breastfeeding or older reproductive age, so the failure rate in these populations may be lower than that in more fertile populations.
4. It is essential that the pill be taken at the same time each day to maximize contraceptive efficacy.
5. Menstrual irregularities are common in users of progestin-only oral contraception and represent the most frequent cause for contraceptive discontinuation.

From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders, Elsevier.

TABLE E7 Summary and Recommendations for Depot Medroxyprogesterone Acetate (DMPA) Use

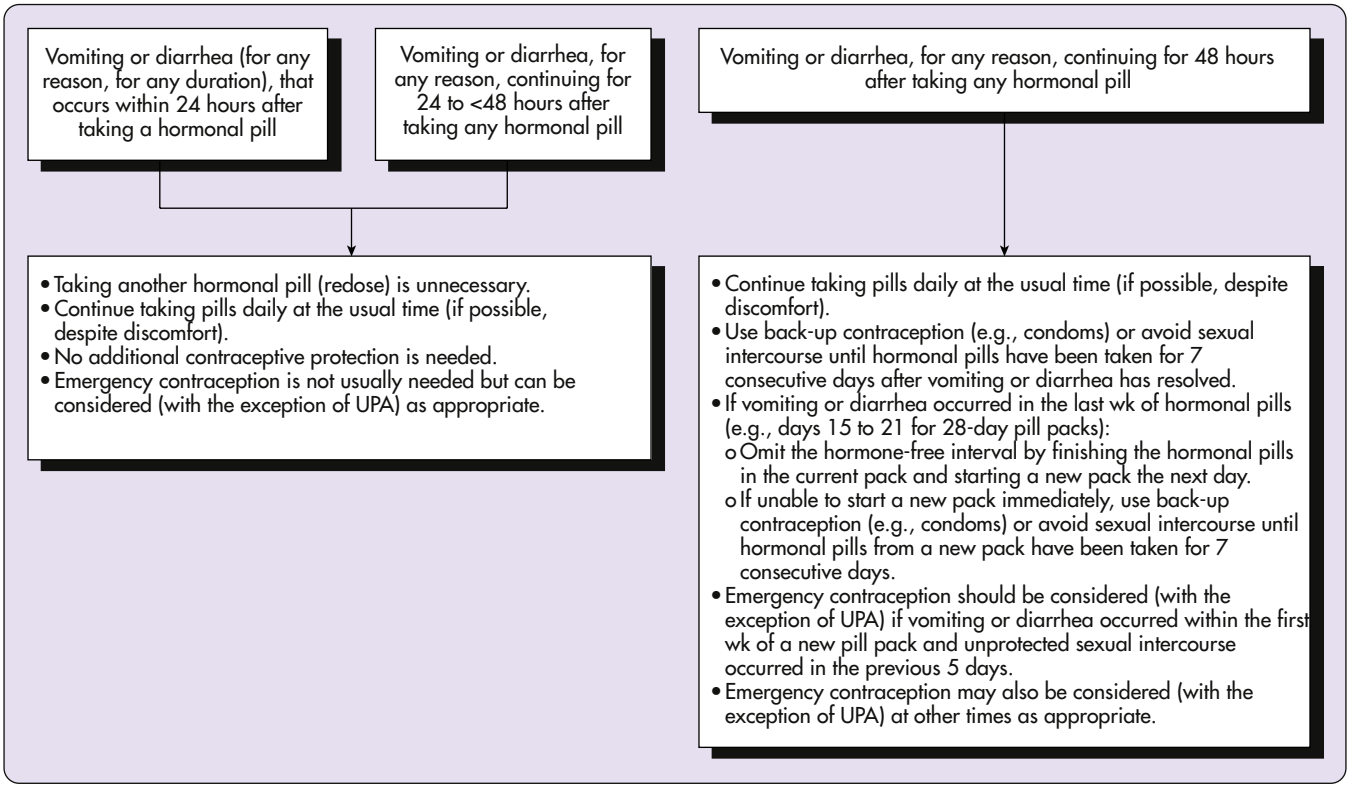
1. DMPA is an excellent method for women who desire a long-term, reversible contraceptive.
2. DMPA primarily acts by inhibiting follicular maturation and ovulation through inhibition of gonadotropin secretion. It also affects cervical mucus.
3. DMPA is available in two formulations: 150 mg/1 ml for IM injection and 104 mg/0.65 ml for SC injection.
4. The ideal time to initiate DMPA is within 5 days of the onset of menses to ensure absence of pregnancy. The dose is repeated every 3 mo, with a 2-wk grace period.
5. Although DMPA does not permanently affect endocrine function, return of fertility may be delayed.
6. Thorough, candid counseling about side effects is important. Women who are well informed when they choose this method of contraception are much more likely to become highly satisfied users with high continuation rates.
7. Menstrual changes occur in all women using DMPA and are the most frequent cause for discontinuation.
8. Because DMPA induces amenorrhea, it can be used for managing a variety of gynecologic and nongynecologic disorders such as menorrhagia, dysmenorrhea, and iron-deficiency anemia.
9. There is no high-quality evidence that use of DMPA increases the risk of developing cancer, cardiovascular disease, or sexually transmitted infection. DMPA use significantly reduces the risk of developing endometrial cancer.
10. There is an association between current DMPA use and decreased bone mineral density; losses in bone mineral density are temporary, reverse after discontinuation of DMPA, and have not been linked to postmenopausal osteoporosis or fractures.

IM, Intramuscular; SC, subcutaneous.
From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders, Elsevier.



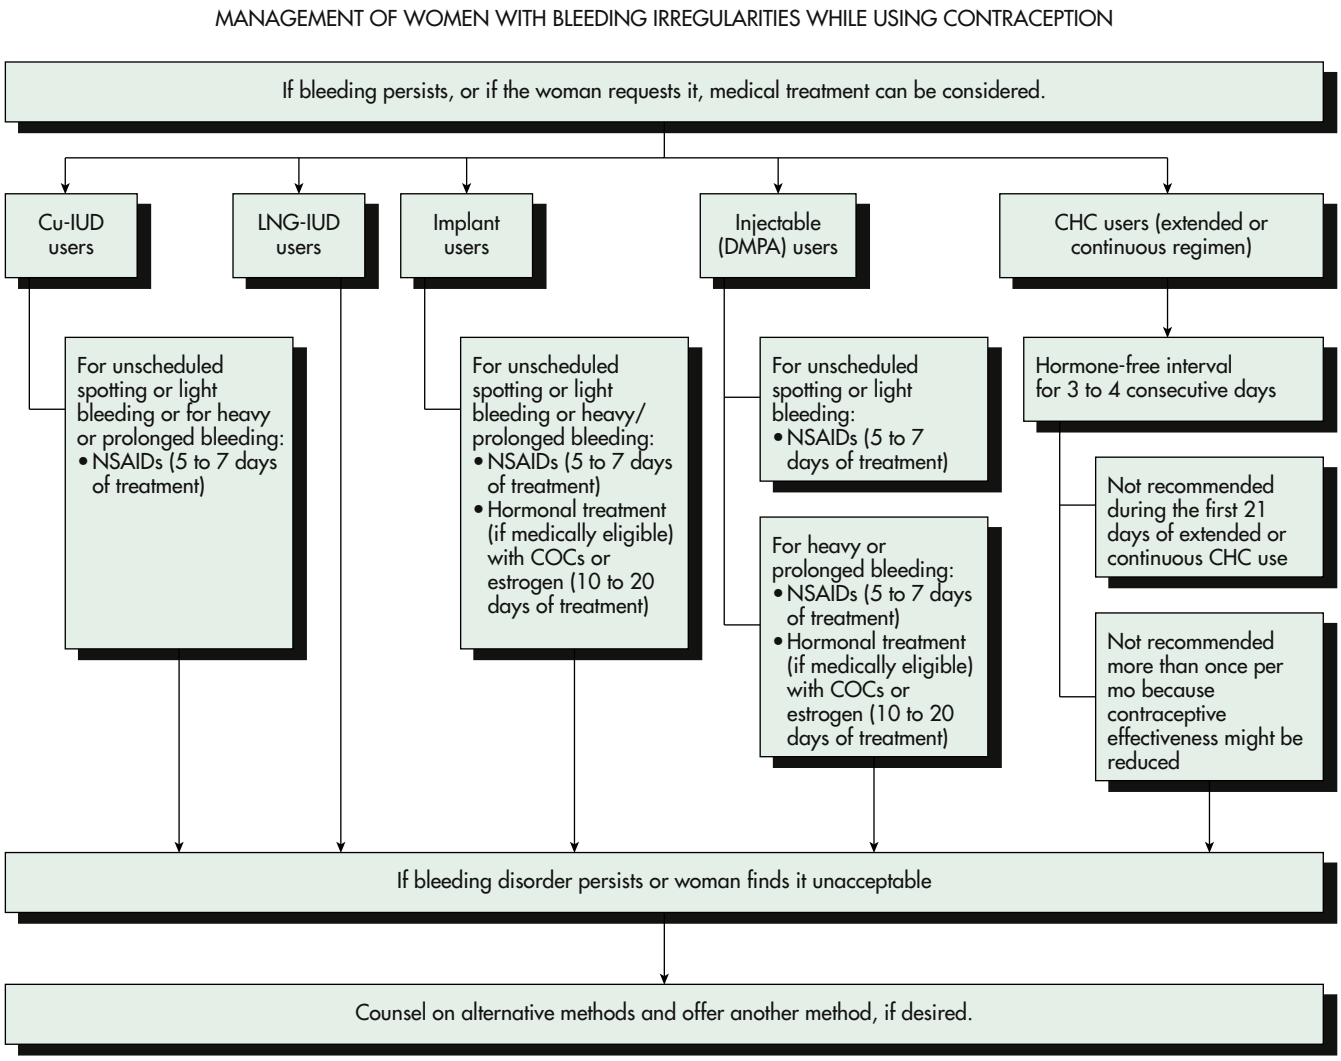
Abbreviation: UPA = ulipristal acetate.
*If removal takes place but the woman is unsure of how long the ring has been removed, consider the ring to have been removed for ≥48 hours since a ring should have been inserted or reinserted.

FIG. E3 Recommended actions after delayed insertion or reinsertion* with combined vaginal ring. (From Curtis KM et al: U.S. selected practice recommendations for contraceptive use, 2016, *MMWR Recomm Rep* 65(4):1-66, 2016.)



Abbreviation: UPA = ulipristal acetate.

FIG. E4 Recommended actions after vomiting or diarrhea while using combined oral contraceptives. (From Curtis KM et al: U.S. selected practice recommendations for contraceptive use, 2016, *MMWR Recomm Rep* 65(4):1-66, 2016.)



Abbreviations: CHC = combined hormonal contraceptive; COC = combined oral contraceptive; Cu-IUD = copper-containing intrauterine device; DMPA = depot medroxyprogesterone acetate; LNG-IUD = levonorgestrel-releasing intrauterine device; NSAIDs = nonsteroidal antiinflammatory drugs.
*If clinically warranted, evaluate for underlying condition. Treat the condition or refer for care. Heavy or prolonged bleeding, either unscheduled or menstrual, is uncommon among LNG-IUD users and implant users.

FIG. E5 Management of women with bleeding irregularities while using contraception. (From Curtis KM et al: U.S. selected practice recommendations for contraceptive use, 2016, *MMWR Recomm Rep* 65(4):1-66, 2016.)

BASIC INFORMATION

DEFINITION

An increase of serum creatinine of >0.5 mg/dl or >25% from baseline that occurs within 48 hours after iodinated contrast media administration (Table E1).

SYNONYMS

Contrast-induced nephropathy (CIN)
Contrast nephropathy
Radiocontrast-induced nephropathy (RCIN)
Contrast-induced acute kidney injury (CA-AKI)

ICD-10CM CODE

N14.1 Nephropathy induced by other drugs, medicaments, and biological substances

EPIDEMIOLOGY & DEMOGRAPHICS

NOMENCLATURE: The term contrast-induced acute kidney injury (CI-AKI), formerly called contrast-induced nephropathy (CIN), implies that contrast medium is the sole etiologic factor of AKI during circumstances of contrast administration. However, frequently, multiple potential etiologic factors are present. The term CI-AKI should only be used when contrast medium administration is the sole putative risk factor for development of AKI. Thus, the term, contrast-associated AKI (CA-AKI) is more appropriate in the majority of cases of AKI that transpire in the context of contrast media administration. Therefore, CI-AKI is a subset of CA-AKI, which encompasses any AKI occurring with 48 hours of contrast media administration.

Low osmolar contrast media (LOCM) are hyperosmolar (~600 mOsm/kg H_2O) relative to isosmolar contrast media (IOCM; ~290 mOsm/kg) and serum (~285 to 295 mOsm/kg). The dimeric structure of IOCM renders them more viscous than LOCM. The majority of contemporary iodinated contrast media are categorized as LOCM. High osmolar iodinated contrast media (HOCM) have higher osmolalities than LOCM and IOCM. HOCM have been replaced by LOCM and IOCM for intravenous administration in modern clinical practice.

INCIDENCE: The overall incidence of CA-AKI has been reported to be approximately 7%, and 11% of acquired AKI cases during hospitalization have been attributed to CA-AKI. However, recent retrospective studies using statistical techniques to minimize confounding factors suggest that CA-AKI incidence has been greatly overestimated. The following opinions and recommendations apply to intravenous (IV), e.g., contrast-enhanced CT, versus intraarterial (e.g., coronary artery angiography) contrast media administration. The latter has unique considerations that do not apply to IV contrast media administration (e.g., requirement for arterial access, atheroembolic complications, and population-specific AKI risk factors).

PEAK INCIDENCE: Incidence rates of CA-AKI vary widely in the literature—a result of discrepancies in type and dose of contrast media used, reason for the imaging study, and definitions of CA-AKI. In one risk prediction model of CA-AKI, 24% of patients in the highest-risk decile undergoing percutaneous coronary intervention (PCI) developed CA-AKI. In another large, retrospective study using propensity-matched controls, no increased risk of acute kidney injury was seen in patients receiving CT with IV contrast compared with those not receiving CT.

SEX AND AGE: Current controversies surrounding the true incidence of CA-AKI call into question the relationship of age to CA-AKI risk. Incidence of CA-AKI appears to increase with age, but age may in fact be simply a risk factor for other causes of AKI that occur in patients receiving contrast media, in particular, declining glomerular filtration rate (GFR). There is no sex predilection for CA-AKI.

RISK FACTORS: Patient-related factors include chronic kidney disease (CKD) with estimated GFR <30 ml/min per 1.73 m^2 (CKD stage 4 or greater), age >75 yr, diabetes mellitus when CKD is present, albuminuria, nonnormovolemic states such as heart failure and volume depletion, and hemodynamic instability. Non–patient-related factors include contrast osmolality, exposure to ionic contrast (rarely used), total contrast dose, sequential contrast doses, concomitant exposure to nephrotoxic agents, and requirement for an intraaortic balloon pump. Although initially thought to enhance risk for CA-AKI, it is unclear if intraarterial contrast administration (e.g., cardiac catheterization) is riskier than IV contrast (e.g., CT). Inpatients have a higher risk of developing CA-AKI than outpatients (Box E1).

TABLE E1 Classification of Iodinated Contrast Media

Chemical Property	Relative Osmolality	Contrast Agent	Osmolality (mOsm/kg H2O)
Ionic	High osmolality	Diatrizoate	1500-1860
		Ioxithalamate	
		Ioxithalamate	
Ionic	Low osmolality	Ioxaglate	600
Nonionic	Low osmolality	Iobitridol	521-695
		Iohexol	
		Iomeprol	
		Iopamidol	
		Iopromide	
		Ioversol	
Nonionic	Isoosmolal	Ioxaglate	270-320
		Iotrolan	
		Iodixanol

BOX E1 Recommendations to Reduce the Risk of Contrast-Induced Nephropathy

1. Identify patients at risk for CA-AKI.
2. Assess the risk-to-benefit ratio of the proposed contrast medium-requiring intervention. Consider alternatives to procedures or imaging that requires iodinated contrast. Do not withhold IV contrast in emergent situations where administration of contrast is necessary for optimal patient care, i.e., risk-to-benefit ratio is justifiable.
3. Assess kidney function by estimated glomerular filtration rate (eGFR) or calculated creatinine clearance before contrast, especially in patients at risk for CA-AKI.
4. Modify correctable risk factors and withhold medications that may increase risk of nephrotoxicity, i.e., withhold nonsteroidal antiinflammatory agents.
5. Use the lowest dose of appropriate contrast medium.
6. In high-risk patients, correct hypovolemia. Stop diuretics and consider IV fluid if no contraindication exists. Heart failure patients should not have diuretics withheld or stopped, unless overdiuresed and volume depleted.
7. Intravenous, isotonic fluid expansion with either 0.9% saline or isotonic sodium bicarbonate solution (150 mM). The optimal fluid type and quantity have not been definitively determined. Volume expansion generally begins 1 hour precontrast administration and continues for 3 to 12 hours postcontrast delivery. Typical regimens are fixed volumes (e.g., 500 ml before and after) or weight-based (1–3 ml/kg/hr). Longer regimens (~12 hours) have been shown to lower the risk of CA-AKI compared to shorter regimens. The patient should be monitored for signs and symptoms of hypervolemia or pulmonary edema.
8. *N*-acetylcysteine prophylaxis is not recommended.
9. Prophylactic hemodialysis or hemofiltration is not recommended.

IV, Intravenous.

Contrast-Associated Acute Kidney Injury (CA-AKI) ALG

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Elevation in serum creatinine generally occurs 24 to 48 hours after administration of contrast. Typically, there are no accompanying symptoms or exam findings. Acute kidney injury usually resolves within 10 days of radiocontrast exposure. Less than 1% of patients with CA-AKI will require dialysis, typically patients with a history of advanced kidney disease.

ETIOLOGY

- Nephrotoxicity occurs due to renal medullary ischemia, a result of vasoconstrictive effects of the contrast medium on the large and small renal arteries.
- Contrast also exerts a direct cytotoxic effect on the vascular endothelium and renal tubular cells, leading to cell injury and death due to generation of damaging reactive oxygen species.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute tubular injury (ATI), atheroembolic renal disease (i.e., postcardiac catheterization), acute interstitial nephritis, prerenal azotemia

WORKUP

- Diagnosis is dependent primarily on history and laboratory values. A search for clinical findings more suggestive of other etiologies of AKI should be conducted (e.g., livedo reticularis or dusky lower-extremity digits in the presence of atheroembolic disease, evidence of systemic infection accompanied by hypotension in the case of sepsis-mediated ATI).
- Urinalysis often reveals a fractional excretion of sodium (FE_{Na}) of <1% despite ATI. A high urine specific gravity may reflect the filtration of hyperosmolar contrast medium. Markers of renal tubular damage including muddy brown granular casts or renal epithelial cells may be seen on urinalysis.
- A kidney biopsy is not recommended for diagnostic confirmation, since biopsy findings are nonspecific for acute tubular injury. If the course of AKI is atypical, a biopsy may be useful to examine for atheroembolic disease or acute interstitial nephritis.

LABORATORY TESTS

- Serum creatinine, urinalysis, and urine microscopy
- Urine and serum sodium and creatinine concentrations for determination of FE_{Na}

IMAGING STUDIES

No radiologic tests aid in the diagnosis of CA-AKI. A renal ultrasound should be obtained if postrenal obstruction is in the differential diagnosis.

Rx TREATMENT

Treatment for CA-AKI is supportive. An algorithm for the prevention and management of CI-AKI is illustrated in Fig. E1. Prevention has been the focus of research efforts.

Recommended strategies for CA-AKI prophylaxis:

- Avoidance of studies and procedures using IV contrast, if not emergent. Consider an alternative imaging modality, if available, for patients at high risk for development of CIN.
- Use low-osmolar nonionic contrast media.
- Minimize contrast volume (dose).
- Volume expansion with IV isotonic fluid. Normal saline (0.9% saline) and sodium bicarbonate solutions are both effective in reducing the risk of CA-AKI.

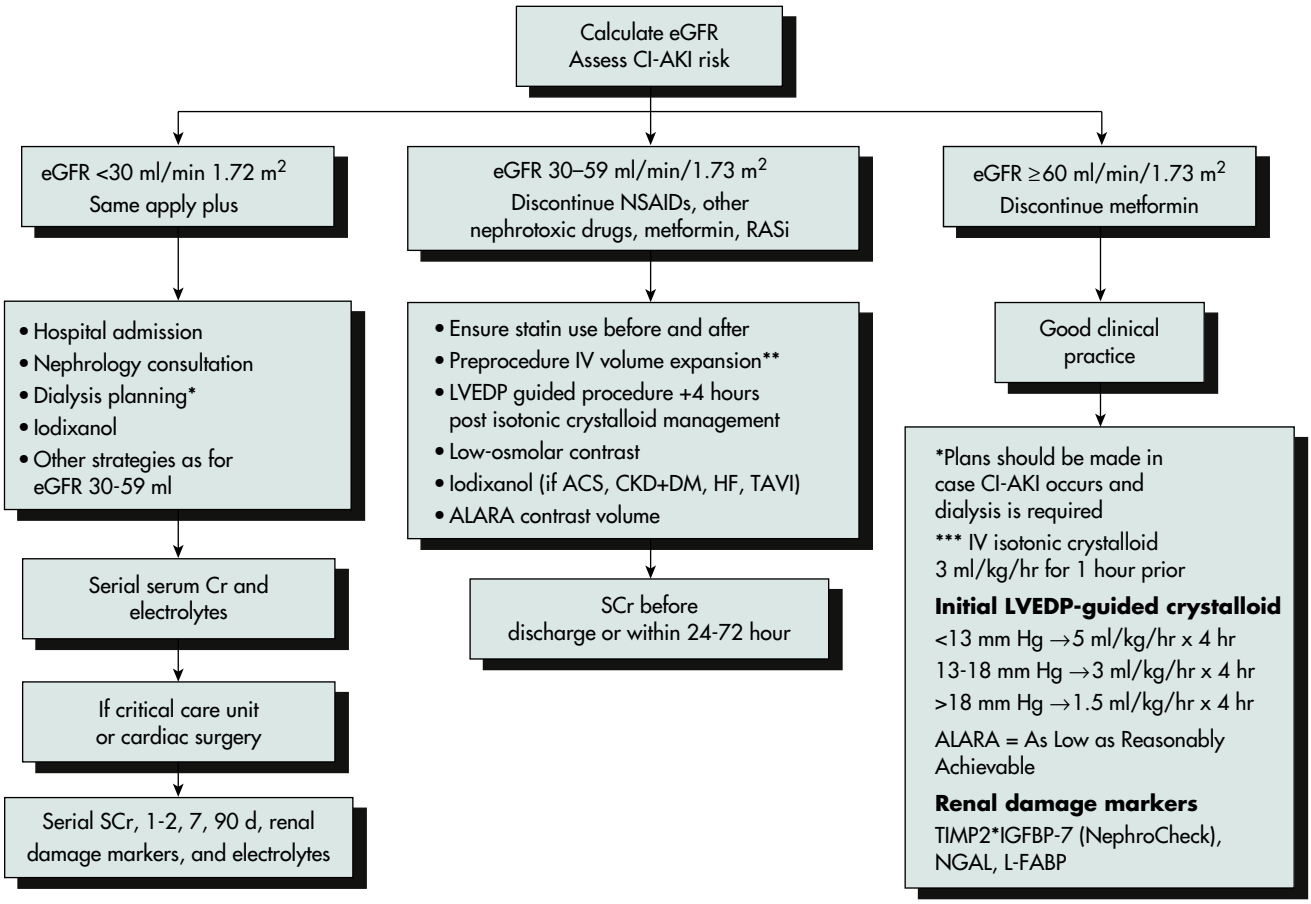

FIG. E1 Algorithm for the prevention and management of contrast-induced acute kidney injury. *ACS,* Acute coronary syndromes; *ALARA,* as low as reasonably achievable; *CI-AKI,* contrast-induced acute kidney injury; *CKD,* chronic kidney disease; *DM,* diabetes mellitus; *eGFR,* estimated glomerular filtration rate; *HF,* heart failure; *IV,* intravenous; *L-FABP,* L-type fatty-acid binding protein; *LVEDP,* left ventricular end-diastolic pressure; *NGAL,* neutrophil-associated lipocalin; *NSAIDs,* nonsteroidal antiinflammatory drugs; *RASi,* renin angiotensin system inhibitors; *SCr,* serum creatinine; *TAVI,* transcatheter aortic valve insertion; *TIMP2*IGFBP-7,* tissue inhibitor of metalloproteinase-2 concentration multiplied by insulin-like growth factor binding protein-7 concentration. (Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.)

Preventive measures for CA-AKI that have *not* shown significant benefit include:

- Oral hydration solutions
- Prophylactic hemodialysis or hemofiltration
- Diuresis from diuretic medications or by osmotic diuretics (e.g., mannitol)
- Vasodilators (e.g., fenoldopam, nifedipine, theophylline)
- Ascorbic acid
- *N*-acetylcysteine

GENERAL PROPHYLAXIS: INTRAVENOUS HYDRATION

- Outpatients with glomerular filtration rate (GFR) <60 ml/min: Withhold medications that reduce GFR, e.g., nonsteroidal antiinflammatory drugs and, possibly, diuretics. An outpatient hydration protocol with either 0.9% saline or sodium bicarbonate may be considered, particularly with eGFRs <45 ml/min per 1.73 m^2. Outpatient hydration protocols have not been rigorously evaluated. Sodium bicarbonate infused at 3 ml/kg per hr for 1 hour preprocedure and 1.5 mg/kg per hour 4 to 6 hours intra- and postprocedure can be performed in the outpatient setting.
- Inpatients with eGFRs <60 ml/min per 1.73 m^2: IV 0.9% saline or D_5W with 150 mM sodium bicarbonate at 1 ml/kg per hr for 6 to 12 hours preprocedure, during the procedure, and 6 to 12 hours postprocedure. With contraindications to IV fluid administration (e.g., congestive heart failure with pulmonary edema), consider postponement of studies involving contrast media, if not emergently indicated. If the procedure is unavoidable, fluid management should be tailored to the individual patient.

DISPOSITION

CA-AKI is usually self-limited. Patients with severe renal functional impairment may require hospitalization for supportive care and potential dialysis.

REFERRAL

- Patients at high risk for CA-AKI or who develop significant CA-AKI should be referred to nephrology.

PEARLS & CONSIDERATIONS

- Although there has been agreement that iodinated contrast dye has nephrotoxic effects, the true incidence of CA-AKI has been reconsidered due to the findings of several recent studies showing that IV contrast administration does not increase the risk of AKI in patients with other reasons for development of AKI. There is concern that potentially beneficial diagnostic contrast media-imaging studies or procedures are being withheld due to fears of developing CA-AKI.
- A diagnosis of CA-AKI can be considered in patients who develop AKI 24 to 72 hours after contrast exposure. Urine sediment may be bland or show signs of tubular injury. The FE_{Na} may be <1% due to altered renal hemodynamics.
- Administration of isotonic IV fluids is appropriate for CKD patients with eGFRs <30 ml/min per 1.73 m^2 or who are otherwise at high risk for CA-AKI.
- Nonsteroidal antiinflammatory drugs and other potential nephrotoxic drugs should be avoided in patients receiving IV contrast media. Metformin does not predispose to CA-AKI, but should be discontinued if AKI occurs. There is no evidence-based guidance regarding continuation or withdrawal of ACEIs or ARBs before contrast administration. Clinical judgment is warranted.
- Diabetic patients should have metformin held before receiving IV contrast due to an increased risk of metformin-related lactic acidosis in the setting of CA-AKI.

Conversion Disorder (Functional Neurologic Symptom Disorder) PTG ALG

BASIC INFORMATION

DEFINITION

Conversion disorder (functional neurologic symptom disorder) presents with symptoms that affect voluntary motor or sensory function or that cause a transient loss of consciousness. Symptoms might include paralysis, blindness, numbness, or the inability to speak. Symptoms can be sporadic, sustained, acute, or chronic. The symptoms, after medical assessment, cannot be explained by a medical condition, direct effects of a substance, or a culturally sanctioned behavior or experience.

Diagnostic features provide evidence of internal inconsistency or incongruity with recognized features of neurological or medical disorders. The symptoms cause clinically significant distress and/or impairment in social, occupational, and other important areas of functioning and warrant medical evaluation. Oftentimes, there is a relevant psychological stressor present, although this is not required to establish the diagnosis. Functional symptoms are not voluntarily produced and are presumed to be unconsciously elaborated.

There is no well-validated physiologic model for conversion disorder, but advances in neuroscience and neuroimaging may reveal new etiologies. A patient found to have conversion disorder should be periodically reevaluated for any medical etiology that has been slow to present or that may be newly diagnosable with advances in medical knowledge and technology.

SYNONYMS

Psychogenic nonepileptic seizure
Psychogenic movement disorder
Hysterical neurosis (historical)
Functional neurologic symptom disorder

ICD-10CM CODES

F44.4	Conversion disorder with motor symptom or deficit
F44.5	Conversion disorder with seizures or convulsions
F44.6	Conversion disorder with sensory symptom or deficit
F44.7	Conversion disorder with mixed symptom presentation
F44.89	Other dissociative and conversion disorders
F44.9	Dissociative and conversion disorder, unspecified

DSM-5 CODE

300.11 Conversion disorder

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence ~5 to 10/100,000 in general population and 20 to 100/100,000 in hospital inpatients
- All ages, including early childhood, but rare in children younger than 10 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presents with one or more motor symptoms (e.g., paralysis, aphonia, difficulty swallowing), sensory symptoms (loss of sensation, double vision, blindness, deafness), or a nonepileptic seizure, or a combination of these symptoms.
- Physical exam findings that are not consistent with anatomical pathways or physiologic mechanisms, such as Hoover sign (weakness of hip extension returns to normal strength with contralateral hip flexion against resistance), weakness of plantar flexion on the exam table in an individual able to walk on tiptoes, positive tremor entrainment test, normal EEG or closed eyes with resistance to opening during nonepileptic seizure, or tubular vision. Features that suggest nonepileptic (conversion) seizures are summarized in Table E1.
- The symptoms or signs persist whether the patient is observed or unobserved, though are typically worse when the patient is attentive to them.
- May occur in the context of documented medical illness (e.g., a patient with epileptic seizure may also have psychogenic seizure).
- May have comorbid axis I or axis II disorders, commonly depression; generalized anxiety; posttraumatic stress disorder (PTSD); or borderline, histrionic, or narcissistic personality disorder.

ETIOLOGY

- Complex interplay of neurologic and psychological factors is not well understood.
- The classic psychodynamic hypothesis is that the conversion symptom is preceded by psychological conflict or stressor and functions to express and manage the psychological distress—that is, "convert" the distress into a neurologic symptom.
- A neurobiologic hypothesis suggests an abnormality in neural networks, possibly triggered by emotional stress. Brain imaging studies suggest alterations in processing of sensory and motor signals.
- Associated with psychiatric comorbidities, most commonly depression, anxiety, PTSD, and personality disorders (most commonly histrionic, borderline, or narcissistic).
- Associated with trauma, interpersonal conflicts, and other life stressors.
- Associated with childhood sexual abuse in many, but not all, studies.
- Associated with preexisting neurologic illness.
- Associated with physical injury that may occur immediately before onset.
- May occur after general anesthesia.
- Family history of medical or psychiatric illness is common.

DIAGNOSIS

Diagnosis is specific to symptom type:

- Psychogenic nonepileptic seizure
- Weakness or paralysis
- Abnormal movement (tremor, dystonic movement, myoclonus, gait disorder)
- Swallowing symptom ("globus hystericus")
- Speech symptom (e.g., dysphonia, slurred speech)
- Anesthesia or sensory loss
- Special sensory symptom (e.g., visual, olfactory, auditory)
- Mixed symptoms

DIFFERENTIAL DIAGNOSIS

Broad differential diagnosis depending on presenting signs and symptoms, including movement disorders, seizure, stroke, spinal disorders, malignancy, vasculitis, infectious disease, autoimmune disorders, vitamin B_{12} deficiency, migraine, dystonia, limbic encephalopathy, stiff

TABLE E1 Features that Suggest Nonepileptic (Conversion) Seizures

Historical Features
History of sexual abuse
History of other unexplained neurologic symptoms occurring during stress
Seizures despite multiple adequate trials of anticonvulsants at therapeutic levels
Features of Event
Events occur with suggestion/provocation
Gradual onset and offset of symptoms
Responsiveness during event
Weeping, speaking, or yelling during the event
Asymmetric clonic activity
Head bobbing or pelvic thrusting
Rapid kicking or thrashing
Prolonged duration of symptoms (>3 minutes)
No EEG abnormalities during the event
Postevent Features
Lucid during immediate postictal period
Able to recall event
Lack of incontinence, tongue biting, or physical injury despite numerous events
Postictal prolactin is normal
Neuropsychological testing suggestive of conversion symptoms

Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry,* ed 7, Philadelphia, 2018, Elsevier.

person syndrome, somatic symptom disorder, factitious disorder, and malingering.

LABORATORY TESTS

Laboratory tests or procedures needed to rule out other medical conditions (e.g., EEG for seizures, EMG for lower motor neuron paralysis, optokinetic drum test in blindness).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Education about illness including explanation and diagnosis. A multidisciplinary treatment team including a neurologist and psychiatrist can be helpful for some patients.
- Medical providers who fail to explain the diagnosis, misattribute the symptoms, and/or continue to pursue medical investigations and procedures can contribute to the patient's belief that there is an irreversible medical cause and thereby risk perpetuating the symptoms. Guidelines for presenting a diagnosis of nonepileptic seizures and developing a treatment plan are summarized in Table E2.
- Cognitive behavioral therapy is often the treatment of choice, although evidence is mixed.
- A long tradition of psychodynamic therapy exists but has not been validated by controlled trials.
- Treatment success has been associated with a caring, long-term relationship between patient and physician.
- Physical and occupational therapy can help reestablish normal function and is important for maintaining strength and function in extended cases of paralysis.
- Studies have shown no additional benefit to hypnosis, although case records describe successful treatment with hypnosis.
- Family therapy and group therapy.
- Physical therapy approaches.

GENERAL Rx

- Antidepressants may be helpful for underlying mood or anxiety disorders.
- Sedation and abreaction: One study showed that sedation with propofol improved symptoms. Abreaction functions as a pharmacologically induced hypnosis in which a lightly sedated patient is interviewed. Amobarbital was used for this purpose in the past. Abreaction is rarely used today.
- Inpatient psychiatric treatment or physical rehabilitation may be required depending on acuity, comorbidities, and functional impairment.

DISPOSITION

Long-term follow-up is essential for recurrent conversion symptoms and underlying mood disorders.

PEARLS & CONSIDERATIONS

COMMENTS

Good prognostic factors: Sudden onset, presence of psychological stressors at onset, short duration between diagnosis and treatment, high level of intelligence, and absence of other psychiatric or medical disorders. Poor prognostic factors: Severe disability, long duration of symptoms, age >40 yr at onset, and convulsions or paralysis as presenting symptoms.

- Studies show an association between sexual trauma and conversion symptoms, although evidence does not support causality due to confounding and methodologic factors.
- Although not well demonstrated, some argue that conversion and somatic symptoms are more prevalent in cultures without an articulated concept of affective disorder or in which mental illness is highly stigmatized.
- A strong therapeutic alliance and education about illness are essential treatment components.

Conversion Disorder (Patient Information)

AUTHOR: **Christina D. Scully, MD**

TABLE E2 Guidelines for Presenting a Diagnosis of Nonepileptic Seizures and Developing a Treatment Plan

Presentation of the Diagnosis	Treatment Plan
1. Frame the diagnosis in a positive way: Symptoms are not due to abnormal electrical activity, and risks of anticonvulsants need not be undertaken.	1. The treatment plan should include as much psychiatric care as the patient will allow. Weekly psychotherapy to assess unconscious motivation, to allow psychoeducation, and to provide support is ideal.
2. Explain that symptoms are likely due to a problem with the *function* of the nervous system, rather than electrical or structural abnormalities.	2. Psychotropic medications should be used to treat comorbid psychiatric symptoms (e.g., associated with major depression).
3. Explain that these symptoms are common and are likely to improve gradually over time. Give specific suggestions regarding how they will improve (e.g., episodes will become less prolonged, then become less frequent, then have fewer symptoms during each episode, and so forth).	3. Regular follow-up from other caregivers is a key component of the treatment plan. Appointments should be scheduled at regular intervals, whether or not the patient is symptomatic, and patients should receive positive reinforcement (and not a decrease in frequency of follow-up) when symptoms subside.
4. Acknowledge the disability that such symptoms have caused and the importance of developing a treatment plan that will improve the function of the nervous system and reduce disability.	4. Physical examinations should be done regularly, but diagnostic studies should be avoided unless clearly indicated.
5. Introduce the idea that anxiety, stress, and mood significantly affect the frequency and severity of these events and that reduction of these symptoms is crucial in the patient's treatment.	5. Despite the diagnosis of nonepileptic seizures, all caregivers should remain vigilant for the possibility that an organic diagnosis has been missed or that nonepileptic seizures and epilepsy are both present.
6. Describe a treatment plan that includes integrated, consistent treatment from providers in psychiatry, neurology, and primary care.

Cor Pulmonale

BASIC INFORMATION

DEFINITION

Cor pulmonale is an alteration in the structure and function of the right ventricle (RV) from pulmonary hypertension (PH) caused by diseases of the upper or lower airways, lungs, or pulmonary vasculature. It is the end result of disorders of pulmonary circulation due to chronic lung disease. Acute cor pulmonale is a disorder in which the RV is dilated and the muscular wall is stretched thin because of acute increase in RV afterload, which usually is a result of acute pulmonary embolism (PE) or acute respiratory distress syndrome (ARDS). This may present with often life-threatening obstructive shock or death, but if the patient survives the initial event, he or she can experience PH, right ventricular hypertrophy, and subsequent right heart failure. Chronic cor pulmonale is a disorder where RV is dilated and hypertrophied because of PH caused by long-standing upper and lower airway disease and not because of left-sided heart disease.

Right-sided heart failure resulting from primary disease of the left heart and congenital heart disease are not considered in this disorder.

SYNONYMS

Acute cor pulmonale
Chronic cor pulmonale

ICD-10CM CODES

I26.0	Pulmonary embolism with acute cor pulmonale
I27.81	Cor pulmonale (chronic)
I26.01	Septic pulmonary embolism with acute cor pulmonale
I26.02	Saddle embolus of pulmonary artery with acute cor pulmonale
I26.09	Other pulmonary embolism with acute cor pulmonale
I26.90	Septic pulmonary embolism without acute cor pulmonale
I26.92	Saddle embolus of pulmonary artery without acute cor pulmonale
I26.99	Other pulmonary embolism without acute cor pulmonale

ETIOLOGY

Acute cor pulmonale is mainly caused by a massive PE and ARDS.

Chronic cor pulmonale is the end result of diverse group of diseases that affect the pulmonary microcirculation in one way or another. Survivors of acute cor pulmonale may also experience chronic disease over the long term. The pathophysiology of cor pulmonae is outlined in Fig. E1.

Common conditions that lead to cor pulmonale:

- Chronic obstructive pulmonary disease (leading cause)
- Interstitial lung disease (ILD)
- Chronic thromboembolic disease
- Sleep disordered breathing
- Chronic mountain sickness
- Connective tissue disease, such as scleroderma
- Miscellaneous: Schistosomiasis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

No symptoms are specific for cor pulmonale. Typically, the symptoms depend on the underlying disease process. The symptoms are most often a result of right ventricular failure:

- Dyspnea, fatigue, chest pain, or syncope with exertion (from PH, RV ischemia, and impaired cardiac output)
- Right upper quadrant abdominal pain and anorexia (from passive hepatic congestion)
- Hoarseness (caused by compression of the left recurrent laryngeal nerve by dilation of the main pulmonary artery; known as *Ortner syndrome*)
- Signs of right ventricular failure: Jugular venous distention, peripheral edema, hepatic congestion, ascites, and a right ventricular third heart sound
- Signs of associated tricuspid regurgitation: Holosystolic murmur heard best along the left parasternal border (augments during inspiration), prominent V-wave on jugular venous pulse, and pulsatile hepatomegaly (in severe tricuspid regurgitation)
- PH will increase the intensity of the pulmonic component of S2, which may be narrowly split
- Rarely, cough and hemoptysis

DIAGNOSIS

WORKUP

Search for an underlying pulmonary process resulting in PH:

- Left ventricular dysfunction should be excluded in the initial assessment with an echocardiogram.
- Echocardiography is essential and defines acute cor pulmonale as the presence of RV dilation, along with a paradoxical interventricular septal motion at end systole, suggesting both RV systolic and diastolic overload.
- Prevalence of cor pulmonale cases attributable to chronic obstructive pulmonary disease (COPD) ranges from 25% to 90%. Workup should include complete pulmonary function tests (PFTs) and chest CT.
- ILD (idiopathic pulmonary fibrosis, connective tissue disease, Pneumoconioses) accounts for 30% to 90% of cases of cor pulmonale.
- In the majority of cases of COPD and ILD, the PH is usually mild to moderate and rarely severe.
- Consideration of obstructive sleep apnea (OSA), chronic thromboembolic disease, pulmonary arterial hypertension, and musculoskeletal disease should be given in the absence of parenchymal lung disease.
- A multiple gated acquisition right ventricular ejection fraction (MUGA RVEF) <45% is considered abnormal. However, MUGA scan is largely being replaced by cardiac MRI (CMR), which is the gold standard for RV function and size.

LABORATORY TESTS

- Complete blood count may show erythrocytosis from chronic hypoxia.
- Arterial blood gas levels confirm hypoxemia and acidosis or hypercapnia.
- B-type natriuretic peptide (BNP) may be elevated from RV dilation and/or hypoxia.
- Connective tissue disorder workup to exclude scleroderma, lupus, rheumatoid arthritis.
- Stool ova and parasites in suspected cases of schistosomiasis.
- HIV testing.

IMAGING STUDIES

- Chest radiograph may show underlying pulmonary disease and evidence of PH (e.g., enlargement of the pulmonary arteries or right atrium and right ventricular dilation or "pruning" of the peripheral vasculature) (Fig. E2).
- ECG (Fig. 3) may reveal right ventricular hypertrophy with R/S ratio >1 in leads V_1 and R/S ratio <1 in leads V_5, V_6, right atrial enlargement

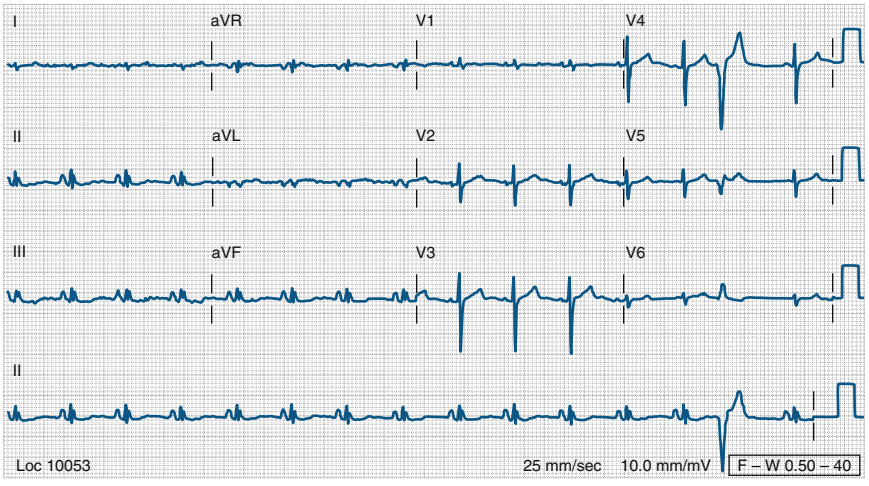

FIG. 3 An electrocardiogram in a patient with chronic cor pulmonale reveals prominent "P pulmonale" and other characteristic features (see text). *aVF*, Augmented vector foot; *aVL*, augmented vector left; *aVR*, augmented vector right. (From Mason RJ: *Murray & Nadel's textbook of respiratory medicine*, ed 5, Philadelphia, 2010, Saunders.)

TABLE 1 Therapeutic Strategies for Cor Pulmonale

Diet and Lifestyle
Smoking cessation
Weight loss
Sodium restriction
Judicious exercise training
Structured rehabilitation and breathing training programs
Avoidance of overexertion
Avoidance of pregnancy
Avoidance of high altitudes
Interventions
Treatment of underlying condition
• COPD (bronchodilators, corticosteroids, antibiotics, oxygen)
• ILD (immunosuppression, oxygen, interferon gamma [investigational])
• Sleep-disordered breathing and alveolar hypoventilation disorders (CPAP, BiPAP, surgery)
• Chronic exposure to high altitudes (return to sea level)
• Chronic thromboembolic disease (anticoagulation, inferior vena cava filters, thromboendarterectomy)
Supplemental oxygen
Pulmonary vasodilators
Anticoagulation
Diuretics
Digitalis glycosides (chronic therapy)
Nonglycoside inotropes (low-dose dobutamine or milrinone in acute severe right heart decompensation with hypoperfusion)
Lung volume reduction surgery
Lung transplantation
Heart-lung transplantation (PAH secondary to complex congenital heart disease)
Percutaneous blade-balloon atrial septostomy (investigational)
• Severe right-sided heart failure
• Recurrent syncope

BiPAP, Bilevel positive airway pressure; *COPD*, chronic obstructive pulmonary disease; *CPAP*, continuous positive airway pressure; *ILD*, interstitial lung disease; *PAH*, pulmonary arterial hypertension.
From Mason RJ: *Murray & Nadel's textbook of respiratory medicine*, ed 5, Philadelphia, 2010, Saunders.

(P-pulmonale), right-axis deviation, or the triad of $S_1Q_3T_3$ indicative of RV strain.
- Echocardiogram to detect right ventricular enlargement and/or hypertrophy and estimate systolic pulmonary artery pressure. In acute cor pulmonale, McConnell sign may be seen, which is a relative hyperkinesis of the RV apex relative to mid-free wall. It is caused by an abrupt increase in RV afterload resulting in regional wall stress.
- PFTs, including spirometry, lung volumes, and diffusion capacity, should be performed in all patients to evaluate for restrictive, obstructive, or combined restrictive-obstructive lung disease. Severe reductions in diffusing capacity that are out of proportion to the parenchymal lung disease can be seen.
- Perfusion scintigraphy (VQ scan) to rule out chronic thromboembolic pulmonary hypertension (CTEPH).
- Cardiac MRI can accurately measure right ventricular dimensions and function.
- Right-sided heart catheterization measures pulmonary artery pressures and pulmonary vascular resistance. It can also determine response to vasodilators. Importantly, right heart catheterization allows assessment of pulmonary capillary wedge pressure, allowing right heart failure from pulmonary venous hypertension due to left heart disease to be ruled out.
- High-resolution computed tomography (HRCT) of the chest is useful in the diagnosis of various pulmonary parenchymal diseases and also for the presence of PH. A main pulmonary artery diameter >29 mm has shown to diagnose the presence of PH with 89% sensitivity and 83% specificity.
- Additional tests: Several additional tests may be undertaken if the underlying cause of cor pulmonale is not exactly clear or to exclude other etiologies. These tests include:
  1. Overnight oximetry for nocturnal hypoxemia
  2. Polysomnography for OSA
  3. CT angiography to detect pulmonary thromboembolism
  4. Six-minute walk test to determine the WHO functional class
  5. Connective tissue disease screening

Rx TREATMENT

The treatment of cor pulmonale is directed toward the underlying etiology while also reversing hypoxemia, improving right ventricular contractility, decreasing pulmonary artery vascular resistance, and improving PH. Table 1 summarizes therapeutic strategies for cor pulmonale.

NONPHARMACOLOGIC THERAPY

- Supplemental oxygen to correct hypoxemia is an important management step in the treatment of cor pulmonale related to hypoxemia. Goal O_2 sat of more than 90% is recommended. Oxygen is the only modality that has demonstrated mortality benefit in patients with group 3 PH.
- Continuous positive airway pressure is used in patients with OSA.
- Sodium and fluid restriction in setting of edema from RV failure.
- Low-level aerobic exercise, avoiding heavy physical exercise or isometric exercises that may cause syncope.

ACUTE GENERAL Rx

- PE is the most common cause of acute cor pulmonale (see "Pulmonary Embolism"). The treatment is anticoagulation, hemodynamic support, and consideration of thrombolytics. Thrombolytics have been reserved for patients with large PE resulting in hemodynamic instability. Catheter-based thrombectomy or surgical embolectomy are potential salvage therapies in patients who cannot receive anticoagulation or thrombolysis, or whose condition continues to deteriorate despite thrombolytics and anticoagulation.
- Acute cor pulmonale may also be seen in cases of ARDS, related to hypercapnia/acidosis, hypoxic pulmonary vasoconstriction, and the effects of mechanical ventilation. The treatment is supportive care for ARDS with low tidal volume ventilation. Extracorporeal membrane oxygen support (ECMO) while awaiting lung recovery from ARDS may also be helpful in maintaining blood oxygenation. Venoarterial ECMO can provide hemodynamic support as well as blood oxygenation.
- In patients with preexisting cor pulmonale, acute pulmonary illnesses or hypoxia can increase PH and worsen right ventricular function. The underlying exacerbating conditions should be treated.
- Careful attention to fluid balance is important in the management of acute decompensated right heart failure. Both overhydration and overdiuresis should be avoided, with careful monitoring of intake and output, electrolytes and creatinine, and hemodynamics.
- Intravenous inotropes may be employed to support right heart contractility in decompensated right heart failure. Dobutamine, milrinone, or epinephrine all have been used in clinical studies with variable success.
- In acutely decompensated right heart failure due to pulmonary arterial hypertension, IV prostanoid medications are the treatment of choice to acutely decrease pulmonary vascular resistance. Oral pulmonary vasodilators may also be added to the IV prostanoids, but should not be initiated as monotherapy in patients with advanced right heart failure from pulmonary arterial hypertension (PAH).

CHRONIC Rx

- Primary treatment of cor pulmonale is treating the underlying cause of hypoxemia. Treatment of primary associated conditions, such as COPD, ILD, and OSA, is indicated in all patients. The long-term use of oxygen therapy results in decreased clinical right

heart failure and improved pulmonary hemodynamics in hypoxic patients.

- Indications for oxygen in chronic obstructive pulmonary disease (COPD) patients include the following:
  1. Resting PaO_2 ≤55 mm Hg on arterial blood gas
  2. Resting PaO 56 to 59 mm Hg if clinical presence of right heart failure with dependent edema, P pulmonale on ECG
  3. Desaturation to SpO_2 ≤88% on oximetry with activity or at night
     a. Right ventricular volume overload should be treated with loop diuretics (e.g., furosemide) and potassium-sparing diuretics such as spironolactone.
- Continuous oxygen therapy has a greater mortality benefit over nocturnal oxygen therapy alone.
- Diuretics should be used for fluid management in cases of fluid overload.
- Anticoagulation with warfarin has been shown to have some benefit in patients with idiopathic pulmonary arterial hypertension and CETPH, provided that there are no obvious contraindications to long-term anticoagulation. Experience with use of new oral anticoagulants (NOACs) for these conditions is still limited, and hence warfarin remains the drug of choice for anticoagulation.
- Digoxin, though controversial, may be employed as an oral inotropic agent to improve right heart contractility and control atrial arrhythmias.
- Selective oral or parenteral pulmonary vasodilators such as oral calcium channel blockers (CCBs), prostanoids, phosphodiesterase inhibitors, and endothelin receptor blockers may be used after a right heart catheterization that establishes PH.
- If vasoreactivity is established, CCBs may be used to lower pulmonary vascular resistance. However, if there is no vasoreactivity, prostanoids such as epoprostenol or treprostinil, phosphodiesterase type 5 inhibitors such as sildenafil, or endothelin receptor blockers such as bosentan and ambrisentan may be tried. However, such agents have been shown to be beneficial in the treatment of idiopathic PAH, PAH related to connective tissue disease, and PAH caused by congenital heart disease. These drugs are effective in patients whose parenchymal destruction is mild or mild to moderate and cor pulmonale is clearly linked to changes in the pulmonary artery itself. However, in patients with severe parenchymal damage, these medications need special caution because they may cause ventilation-perfusion mismatch. The soluble guanylate cyclase stimulator riociguat has been shown to improve exercise capacity and WHO functional class in CTEPH and idiopathic PH. It can be used as monotherapy or in combination with endothelin receptor antagonists or prostanoids. In small observational studies, long-term treatment with riociguat has been shown to reduce RV size and improve RV function.
- Pulmonary endarterectomy may be curative in the special case of cor pulmonale due to chronic thromboembolic PH in proximal pulmonary arteries. Before proceeding with surgery, a trial of 3 mo of anticoagulation is required.
- Atrial septostomy is a salvage option for patients with ongoing decompensated right heart failure from PAH despite pulmonary vasodilators. Such patients should undergo rapid assessment for possible transplantation.
- Lung transplantation or heart-lung transplantation should be considered in the setting of cor pulmonale from lung diseases or from pulmonary vascular disease.
- All patients should be encouraged to quit smoking and should be vaccinated against influenza and with two doses of pneumococcal vaccine.

DISPOSITION

Patients with cor pulmonale should have regular assessment of their functional class (e.g., New York Heart Association or World Health Organization [NYHA or WHO] functional class); worse functional class indicates a poorer prognosis. Other poor prognostic features include high right atrial pressure, impaired cardiac output, elevated BNP levels, low systemic blood pressure, and poor exercise tolerance as demonstrated by a 6-minute walk test.

REFERRAL

Patients with pulmonary disease who have progressed to cor pulmonale should be followed up by a pulmonologist and a tertiary care center that specializes in treatment of advanced PH.

PEARLS & CONSIDERATIONS

- Identification and treatment of the underlying cause of cor pulmonale is key.
- Prognosis and treatment are related to the underlying cause, whereas the presence of cor pulmonale is merely a marker of the underlying disease severity.
- Right heart catheterization is the gold standard to establish diagnosis and to determine treatment, including response to calcium channel blockers, prostanoids, and endothelin receptor blockers.

COMMENTS

There is increasing interest in selective pulmonary vasodilators to improve right ventricular heart function in patients with cor pulmonale outside of the setting of idiopathic PAH, PAH related to connective tissue disease, and PAH related to congenital heart disease. However, more data on the safety and efficacy of these agents, especially in the setting of hypoxemic lung disease, is needed.

The importance of maintaining or improving right heart function, rather than solely lowering pulmonary pressures, is becoming increasingly apparent in the therapeutic management of patients with PH and right heart failure.

Long-term survival is related to improved pulmonary artery hemodynamics (lower mean PAP). Improved pulmonary hemodynamics are apparent within the first 6 mo of oxygen therapy. Continuous oxygen therapy improves pulmonary hemodynamics with more than 19 hr/day therapy.

BASIC INFORMATION

DEFINITION

A corneal abrasion is a loss of surface epithelial tissue of the cornea caused by trauma.

SYNONYMS

Corneal erosion (term for recurrent epithelial defect from previous abrasion)
Corneal contusion
Corneal epithelial defect
Corneal ulcer (term suggests infiltrative infection of an epithelial defect)

ICD-10CM CODES	
S05.00XA	Injury of conjunctiva and corneal abrasion without foreign body, unspecified eye, initial encounter
S05.01XA	Injury of conjunctiva and corneal abrasion without foreign body, right eye, initial encounter
S05.02XA	Injury of conjunctiva and corneal abrasion without foreign body, left eye, initial encounter

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): A universal problem. Corneal abrasions comprise 8% of all eye presentations in primary care
PEAK INCIDENCE: Childhood through active adulthood and older and debilitated patients
PREDOMINANT AGE: Any age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Haziness of the cornea
- Disruption of the corneal surface
- Redness and injection of the conjunctiva, often around the edge of the cornea, limbus
- Pain
- Light sensitivity
- Tearing
- Gritty or foreign-body feeling
- Pain on opening or closing eyes

ETIOLOGY

- Trauma (direct mechanical event)
- Foreign body (on cornea or upper tarsal conjunctiva, found with lid eversion)
- Contact lenses
- Chemical or flash ultraviolet burns

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute-angle closure glaucoma (pupil may be fixed, supraorbital headache)
- Herpes ulcers and other corneal ulcers (infections may appear white and hazy)
- Foreign body in the cornea (be certain it is not a keratitis)
- Infectious keratitis (be cautious in contact lens wearers; bacterial infections are common, and symptoms are similar)
- Autoimmune corneal ulceration (RA, SLE): Peripheral ulceration

WORKUP

- Fluorescein staining, slit lamp evaluation. After fluorescein staining of the cornea, an abrasion will appear yellow under normal light and green in cobalt blue light (Fig. E1).
- Assessment of visual acuity. Vision loss requires referral.
- Intraocular pressure.
- Rule out corneal laceration (flattened anterior chamber with perforation; refer urgently).
- Rule out other eye pathology. Inspect anterior chamber for blood (hyphema) or pus (hypopyon). If present, refer immediately to ophthalmologist.
- Examine for foreign bodies and remove them if present. (Evert upper eyelid to locate foreign body on the palpebral conjunctiva.)
- Confirm red reflex to rule out significant globe injury.
- Significant blunt or sharp trauma to the cornea or globe should be referred for evaluation.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Bandage contact lens can help speed healing for large epithelial abrasions.
- Warm compresses.
- Pressure dressing (patching) is controversial. Although eye patching traditionally has been recommended in the treatment of corneal abrasions, several studies show that patching does not help and should be avoided since it may hinder healing.
- Removal of any foreign particles if present.

ACUTE GENERAL Rx

- Topical antibiotics such as 10% sulfacetamide or ofloxacin 0.3% solution two drops qid are commonly prescribed to prevent bacterial superinfection, but evidence for their use is lacking and should generally be avoided. Ointment forms are also often used (e.g., erythromycin, bacitracin ophthalmic qid) to also improve corneal surface lubrication. Antipseudomonal topical antibiotics are,

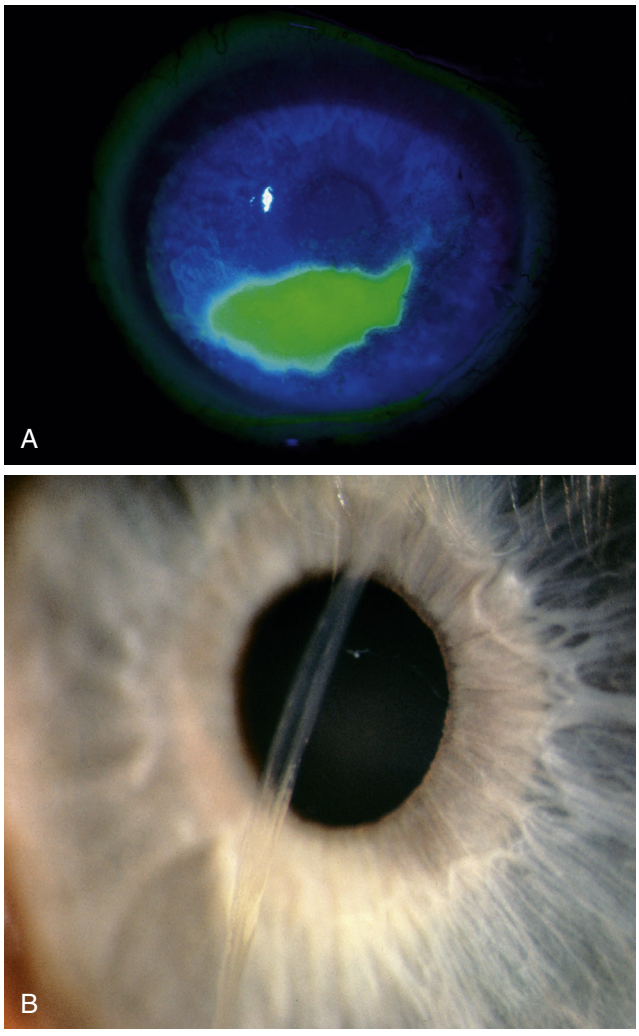

FIG. E1 Corneal complications of blunt trauma. A, Large corneal abrasion stained with fluorescein. **B,** Tears in Descemet membrane. (Courtesy C. Barry [Fig. **A**] and R. Curtis [Fig. **B**]. In Bowling B: *Kanski's clinical ophthalmology, a systematic approach,* ed 8, Philadelphia, 2016, Elsevier.)

however, recommended for contact lens–related abrasions.
- Pressure patching of eye with eyelid closed is no longer recommended because it can result in decreased oxygen delivery, increased moisture, and a higher chance of infection.
- Cycloplegics such as 5% homatropine are often prescribed to relieve ciliary muscle spasm; however, their benefit has been questioned, and they are no longer routinely recommended.
- Topical nonsteroidal antiinflammatory drugs (NSAIDs) (e.g., diclofenac 0.1% or ketorolac 0.5%) one drop qid may be used for pain relief.
- Topical anesthetic drops immediately improve comfort for purposes of examination, but repeated use can lead to severe problems, delayed or arrested healing, infections, perforations, and loss of the eye.
- Oral NSAIDs may be used for severe pain.

DISPOSITION

Follow-up in 24 hr, then every 3 days until abrasion has cleared and vision has returned to normal. Less frequent follow-up is appropriate for abrasions ≤4 mm or for uncomplicated abrasions.

REFERRAL

To ophthalmologist if patient has no relief within 24 hr or for patients with deep eye injuries, foreign bodies that cannot be removed, or suspected recurrent corneal erosion or infections.

PEARLS & CONSIDERATIONS

COMMENTS

- Never give the patient topical anesthetic to use at home because these can cause decompensation of the cornea, severe delay of epithelial healing, and permanent damage.
- Corticosteroid drops (e.g., dexamethasone, prednisolone) should be avoided, since they can delay healing and exacerbate some corneal infections (herpes viral keratitis, pseudomonas, and fungal ulcers).
- Most corneal abrasions heal in 24 to 48 hr and rarely progress to corneal erosion or infection.
- Improvement in pain is a good indication of corneal epithelial healing. Severe worsening of pain could indicate corneal bacterial infection (keratitis) and should be evaluated urgently.

RELATED CONTENT

Corneal Foreign Body or Abrasion (Patient Information)

AUTHOR: **R. Scott Hoffman, MD**

SUGGESTED READING

Wipperman JL, Dorsch JN: Evaluation and management of corneal abrasions, *Am Fam Physician* 87(2):114-120, 2013.

BASIC INFORMATION

DEFINITION

Corneal ulceration refers to the disruption of the corneal surface and/or deeper layers caused by trauma, contact lenses, infection, degeneration, or other means. Rather than simple epithelial abrasion, ulceration implies inflammation, such as with infection of the deeper corneal stroma.

SYNONYMS

Infectious keratitis with ulceration
Bacterial keratitis with ulceration
Viral keratitis with ulceration
Fungal keratitis with ulceration

ICD-10CM CODES	
H16.009	Unspecified corneal ulcer, unspecified eye
E50.3	Vitamin A deficiency with corneal ulceration and xerosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Four to six cases per month seen by an average general ophthalmologist
PREVALENCE (IN U.S.): Common
PREDOMINANT SEX: Either
PREDOMINANT AGE: All ages

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Localized, well-demarcated, infiltrative lesion with corresponding focal ulcer or oval, yellow-white stromal suppuration with thick mucopurulent exudate and edema. Usually red, angry-looking eye with infiltration in surrounding area of cornea.
- Eye possibly painful, with conjunctival edema and infection (pain is a helpful indicator of progression or improvement in infectious keratitis).
- Active keratitis is usually extremely painful, with photophobia and ciliary injection.
- Sterile neurotrophic ulcers with tissue breakdown and no pain.
- Fig. E1 illustrates various deep corneal lesions.

ETIOLOGY

- Complication of contact lens wear, trauma, or diseases such as herpes simplex keratitis or keratoconjunctivitis sicca. Often associated with collagen vascular disease and severe exophthalmos and thyroid disease.
- Viral causes often contagious.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- *Pseudomonas* and pneumococcus and other bacterial infection: Virulent
- *Moraxella, Staphylococcus,* α-*Streptococcus* infection: Less virulent
- Herpes simplex infection or disease caused by other viruses
- Contact lens ulcers differ
- Autoimmune keratitis (e.g., peripheral ulceration with rheumatoid arthritis, systemic lupus erythematosus [RA, SLE])
- Acute angle closure glaucoma

WORKUP

- Fluorescein staining, slit lamp
- Appearance often typical
- Differentiate carefully with contact lens wearers
- Note previous eye surgery or laser vision correction

LABORATORY TESTS

Microscopic examination and culture of scrapings are indicated for vision-threatening keratitis (lesions are large or central location in the cornea) or atypical presentations, such as keratitis not responding to treatments as expected.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Warm compresses for blepharitis, eyelid hygiene
- Bandage contact lenses
- Stop contact lens wearing

ACUTE GENERAL Rx

- An ophthalmic emergency; refer to ophthalmologist same day.
- Intense antibiotic and antiviral therapy may be needed for infectious keratitis.
- Topical antibiotics (often broad-coverage, new-generation fluoroquinolones).
- Nonsteroidal antiinflammatory drugs and cycloplegic may help with comfort.
- Bacterial infection: Subconjunctival cefazolin or gentamicin (e.g., topical Zymar, Vigamox).
- Fungal infection (rare): Hospitalization and topical application of antifungal agents.
- Herpes: Viral keratitis can have similar symptoms; should avoid steroid drops unless diagnosis is near certain and showing improvement because viral keratitis can worsen with steroids.
- Acanthamoeba keratitis may be suspected, particularly in contact lens wearers with severe pain who are unresponsive to other treatments.

DISPOSITION

Ideally treated by an ophthalmologist if the patient does not rapidly respond to antibiotics (within 24 hr). Improvement in pain is often a good indication of improvement in the infection.

Corneal ulcer may be managed every 1 to 2 days until epithelium has healed over and improvement is apparent.

PEARLS & CONSIDERATIONS

- Always stop contact lens wearing.
- Always refer ulcers to ophthalmologist.
- Never treat with topical anesthetics or steroids.

COMMENTS

Do not use topical steroids because herpes, fungal, or other ulcers may be aggravated, leading to perforation of the cornea. Antibiotics may delay response and result in overgrowth of nonbacterial (fungal and amoebic) pathogens.

BASIC INFORMATION

DEFINITION

Coronary artery disease (CAD) is a clinical syndrome that suggests limitation of coronary blood flow to the myocardium as a result of atherosclerotic lesions. Atherosclerosis can be defined as the narrowing of the artery due to plaque formation in the setting of lipid accumulation inside the arterial walls. It is silent in the early stages and characterized by exertional symptoms in later stages as described in the following.

This topic addresses only stable CAD. Acute coronary syndromes (ACS), angina pectoris, and myocardial infarction are addressed as separate topics elsewhere.

SYNONYMS

Atherosclerotic heart disease
CAD
Chronic stable angina
Stable ischemic heart disease
Coronary arteriosclerosis

ICD-10CM CODES

I25.0	Atherosclerotic cardiovascular disease
I25.1	Atherosclerotic heart disease
I25.10	Atherosclerotic heart disease of native coronary artery without angina pectoris
I25.110	Atherosclerotic heart disease of native coronary artery with unstable angina pectoris
I25.111	Atherosclerotic heart disease of native coronary artery with angina pectoris with documented spasm
I25.118	Atherosclerotic heart disease of native coronary artery with other forms of angina pectoris
I25.119	Atherosclerotic heart disease of native coronary artery with unspecified angina pectoris

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: For persons who are 40 yr old, the lifetime risk of developing CAD is 49% in men and 32% in women. The risk increases with age in both men and women; however, the incidence in women lags behind that seen in men by approximately 10 yr.

The incidence in premenopausal women is relatively low, while the incidence increases significantly in postmenopausal women.

The initial presentation in men is more likely to be that of a myocardial infarction, whereas women often present initially with angina.

PREVALENCE: The 2017 Heart Disease and Stroke Statistics update from the American Heart Association estimated that 16.5 million Americans ≥20 yr of age have CAD. There is a slight male predominance at 55%, with incidence increasing with age. CAD prevalence is 7.9% for men and 5.1% for women.

RISK FACTORS: The most prevalent risk factors include age, male sex, hypertension, hyperlipidemia, diabetes mellitus, obesity, tobacco use, family history, and peripheral vascular disease. Coronary plaque, especially noncalcified plaque, is more prevalent and extensive in HIV-infected men, independent of CAD risk factors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Left anterior chest discomfort often described as squeezing, heavy pressure, and burning. Associated symptoms include fatigue, dyspnea, weakness, lightheadedness, nausea, diaphoresis, altered mental status, and syncope.
- Angina typically lasts 3 to 5 min but usually does not last more than 30 min.
- Women and diabetics may not present with classic symptoms, but may manifest more frequently with dyspnea or GI complaints.
- Discomfort is elicited by physical exertion, emotional stress, cold exposure, consumption of a large meal, and smoking.
- Early coronary disease is asymptomatic.
- Stigmata of atherosclerosis may include xanthelasma, tendon xanthomata, and evidence of peripheral vascular disease such as claudication and diminished peripheral pulses.

ETIOLOGY

The development of atherosclerosis occurs over many yr. The order of events has been well studied. Multiple factors contribute to the pathogenesis, including endothelial dysfunction, dyslipidemia, inflammatory conditions, and smoking. Under such conditions, cholesterol molecules, primarily low-density lipoprotein (LDL), adhere to the intima of the vessel walls and are taken into the intimal layers. LDL is then oxidized, causing cytokine release, which initiates adhesion molecule expression on endothelial layers. Monocytes are then recruited and pass across the endothelium, where they digest the LDL and become "foam cells." Smooth muscle cells then migrate from the media to the intima. This causes further smooth cell proliferation and fibrosis to occur. In later stages, calcification of the matrix also develops. This causes a relatively acellular fibrous capsule to surround a lipid-rich core. This "plaque" then causes narrowing of the vessel lumen, ultimately leading to symptoms related to ischemia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS OF ACUTE CHEST PAIN

- Cardiovascular causes
  1. Acute coronary syndrome
  2. Aortic dissection
  3. Pericarditis
  4. Coronary arterial vasospasm
- Pulmonary causes
  1. Pulmonary embolism
  2. Pneumonia
  3. Pleuritis
  4. Pneumothorax
- Gastrointestinal causes
  1. Esophageal spasm
  2. Esophagitis
  3. GERD
- Chest wall causes
  1. Rib fracture
  2. Sternoclavicular arthritis
  3. Herpes zoster
  4. Costochondritis
- Psychiatric causes
  1. Anxiety disorders

WORKUP

See Fig. 1. ACCF/HFA guidelines for stress testing and advanced imaging are summarized in Tables 1 to 3.

LABORATORY TESTS

- Focused metabolic studies to rule out noncardiac causes (BMP, liver function tests).
- Complete blood count can help rule out anemia-related chest discomfort.
- Fasting cholesterol panel is important in assessment of lipid-related risk factors.
- Hemoglobin A1c is important to follow glycemic control.
- High-sensitivity C-reactive protein.

IMAGING STUDIES

- Electrocardiography (ECG) is important for assessing for prior cardiac injury or ischemia.
- Exercise treadmill test (ETT) is the gold standard to assess physiologic cardiac stress response if the patient is able to exercise and has a normal baseline ECG.
- Stress tests combined with imaging is the next best option if ETT cannot be performed due to physical limitation or if baseline ECG is abnormal.
- Echocardiogram to assess left ventricular ejection fraction (LVEF) and the presence of wall motion abnormalities.
- Although not used in the acute setting, a coronary artery calcium (CAC) score can be used to improve CVD risk classification. The CAC is estimated from noncontrast CT (Fig. E2) images. Normal coronary arteries do not have plaques or calcium, and the normal score is 0. A CAC score of 300 or higher, or 75th percentile or higher for age, sex, and ethnicity is considered a high risk. According to the recent ACC/AHA guidelines, CAC is most appropriate among adults with an estimated 10-yr ASCVD risk <7.5% in whom questions remain about whether statin therapy is indicated. A CAC score >75th percentile for age, sex, and ethnicity is considered high risk and would justify revising a patient's risk upward.
- Those with high-risk features (Box 1) should undergo coronary angiography to assess coronary anatomy for revascularization.
- Cardiac computed tomography angiography is an emerging imaging modality that can be considered as an alternative to stress testing.

TABLE 3 ACCF/AHA Guidelines for Coronary Angiography to Assess Risk in Patients with Known or Suspected Stable Ischemic Heart Disease

Class	Indication	Level of Evidence
I (indicated)	1. Patients with SIHD who have survived sudden cardiac death or potentially life-threatening ventricular arrhythmia should undergo coronary angiography to assess cardiac risk.	B
	2. Patients with SIHD in whom symptoms and signs of heart failure develop should be evaluated to determine whether coronary angiography should be performed for risk assessment.	B
	3. Coronary arteriography is recommended for patients with SIHD whose clinical characteristics and results of noninvasive testing indicate a high likelihood of severe IHD and when the benefits are deemed to exceed risk.	C
IIa (good supportive evidence)	1. Coronary angiography is reasonable to further assess risk in patients with SIHD who have depressed LV function (EF <50%) and moderate-risk criteria on noninvasive testing with demonstrable ischemia.	C
	2. Coronary angiography is reasonable to further assess risk in patients with SIHD and inconclusive prognostic information after noninvasive testing or in patients for whom noninvasive testing is contraindicated or inadequate.	C
	3. Coronary angiography for risk assessment is reasonable for patients with SIHD who have unsatisfactory quality of life because of angina, have preserved LV function (EF >50%), and have intermediate-risk criteria on noninvasive testing.	C
III (no benefit)	1. Coronary angiography for risk assessment is not recommended in patients with SIHD who elect not to undergo revascularization or who are not candidates for revascularization because of comorbid conditions or individual preferences.	B
	2. Coronary angiography is not recommended to further assess risk in patients with SIHD who have preserved LV function (EF >50%) and low-risk criteria on noninvasive testing.	B
	3. Coronary angiography is not recommended to assess risk in patients who are at low risk according to clinical criteria and who have not undergone noninvasive risk testing.	C
	4. Coronary angiography is not recommended to assess risk in asymptomatic patients with no evidence of ischemia on noninvasive testing.	C

ACCF/AHA, American College of Cardiology Foundation/American Heart Association; *EF,* ejection fraction; *LV,* left ventricle; *SIHD,* stable ischemic heart disease.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

BOX 1 Noninvasive Risk Stratification

High risk (>3% annual mortality rate)
1. Severe resting left ventricular dysfunction (LVEF <35%).
2. High-risk treadmill score (≤–11).
3. Severe exercise left ventricular dysfunction (exercise LVEF <35%).
4. Stress-induced large perfusion defect (particularly if anterior).
5. Stress-induced multiple perfusion defects of moderate size.
6. Large, fixed perfusion defect with LV dilation or increased lung uptake (thallium-201).
7. Stress-induced moderate perfusion defect with LV dilation or increased lung uptake (thallium-201).
8. Echocardiographic wall motion abnormality (involving >2 segments) developing at low dose of dobutamine (≤10 mg/kg/min) or at a low heart rate (<120 beats/min).
9. Stress echocardiographic evidence of extensive ischemia.

Intermediate risk (1% to 3% annual mortality rate)
1. Mild/moderate resting left ventricular dysfunction (LVEF 35% to 49%).
2. Intermediate-risk treadmill score (score between –11 and <5).
3. Stress-induced moderate perfusion defect without LV dilation or increased lung intake (thallium-201).
4. Limited stress echocardiographic ischemia with a wall motion abnormality only at doses of dobutamine involving ≤2 segments.

Low risk (<1% annual mortality rate)
1. Low-risk treadmill score (≥5).
2. Normal or small myocardial perfusion defect at rest or with stress.
3. Normal stress echocardiographic wall motion or no change of limited resting wall motion abnormalities during stress.

LV, Left ventricle; *LVEF,* left ventricular ejection fraction.

- Coronary angiography is useful for both diagnostic and therapeutic interventions if there is evidence of significant ischemia by noninvasive assessment or progressive symptoms despite optimal medical therapy (as in the following).

Rx TREATMENT

- See Fig. 3. Table 4 summarizes ACCF/AHA guidelines for risk factor modification. Note that hypertension and cholesterol management guidelines have been revised since release of these CAD guidelines, and these are summarized in the "Hypertension" and "Hypercholesterolemia" chapters in this text.
- Successful treatment of CAD entails minimizing the likelihood of major adverse cardiac events (MACE), which include death, myocardial infarction, need for emergent coronary artery bypass grafting, or target lesion revascularization, while maximizing health and function.

NONPHARMACOLOGIC THERAPY

LIFESTYLE MODIFICATION:
- ≥150 min/wk of moderate-intensity activity or ≥75 min/wk of vigorous-intensity activity or a combination thereof (for adults) as 1 of the 7 components of ideal cardiovascular health.
- Mediterranean diet with a focus on vegetables, fruit, fish, whole grains, and olive oil has proven to reduce cardiovascular events to a degree greater than low-fat diets and equal to or greater than the benefit observed in statin trials.
- Smoking cessation.
- Weight reduction can reduce various risk factors with improved lipid and glycemic control.

THERAPEUTIC INTERVENTIONS: Coronary angiography with PCI or CABG for patients on optimal medical therapy with persistent symptoms.

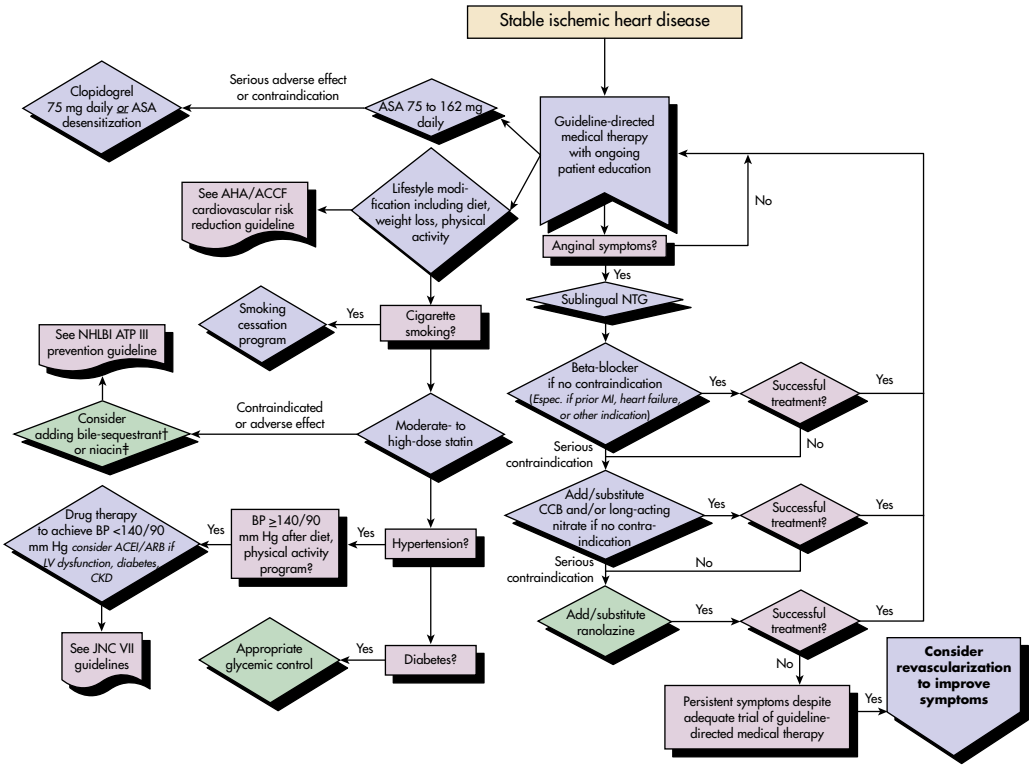

FIG. 3 Algorithm for guideline-directed medical therapy for patients with SIHD.*

*The algorithms do not represent a comprehensive list of recommendations (see text for all recommendations). †The use of bile acid sequestrant is relatively contraindicated when triglycerides are ≥200 mg/dl and is contraindicated when triglycerides are ≥500 mg/dl. ‡Dietary supplement niacin must not be used as a substitute for prescription niacin. *ACCF,* American College of Cardiology Foundation; *ACEI,* angiotensin-converting enzyme inhibitor; *AHA,* American Heart Association; *ARB,* angiotensin-receptor blocker; *ASA,* aspirin; *ATP III,* Adult Treatment Panel 3; *BP,* blood pressure; *CCB,* calcium channel blocker; *CKD,* chronic kidney disease; *JNC VII,* Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure; *LV,* left ventricular; *MI,* myocardial infarction; *NHLBI,* National Heart, Lung, and Blood Institute; *NTG,* nitroglycerin; *SIHD,* stable ischemic heart disease. (From 2012 ACCF/AHA/ACP/AATS/PCNA/SCAI/STS Guideline for the Diagnosis and Management of Patients With Stable Ischemic Heart Disease: A report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, and the American College of Physicians, American Association for Thoracic Surgery, Preventive Cardiovascular Nurses Association, Society for Cardiovascular Angiography and Interventions, and Society of Thoracic Surgeons, *J Am Coll Cardiol* 60:e44-e164, 2012.)

ACUTE GENERAL Rx FOR STABLE ANGINA

- Rest.
- Sublingual nitroglycerin if rest does not provide adequate relief.

CHRONIC Rx

- Antianginal therapy:
  1. Nitrates (isosorbide mononitrate and isosorbide dinitrate). These medications treat ischemia by venodilation to decrease preload, dilate epicardial coronary arteries, and recruit coronary collaterals. Furthermore, they attenuate platelet aggregation. Although they do not influence survival or decrease cardiovascular death in patients with chronic CAD, they do lower the rate of angina frequency and increase time to ischemic ECG findings on treadmill testing.
  2. Beta-adrenergic antagonists (metoprolol, atenolol, carvedilol, or any other beta-blockers with the exception of those with intrinsic sympathomimetic activity). These medications work to relieve angina by decreasing myocardial oxygen demand by reducing heart rate, blood pressure, and contractility. Drugs should be titrated to a heart rate of 50 to 60 beats/min at rest and ≤100 beats/min with exercise.
  3. Calcium channel blockers (CCBs; amlodipine or verapamil). The antianginal efficacy of CCBs is comparable to beta-blockers; however, the efficacy of monotherapy for reducing MI or cardiac death has not been demonstrated.
  4. Ranolazine. This is a selective inhibitor of late sodium influx into myocytes, which leads to decreased myocardial contractility. It can be used in combination with beta-blockers and significantly reduces frequency of angina and increases exercise duration and time to onset of angina (CARISA trial). Although it rarely may cause QT prolongation, it has not been linked to any clinically important arrhythmias.
  5. May benefit from combination therapy of the above.
- Antiplatelet therapy:
  1. Aspirin therapy (81 to 162 mg/day).
  2. Clopidogrel for those intolerant to aspirin therapy.
  3. Combination of aspirin and clopidogrel does not reduce cardiovascular events in stable CAD (CHARISMA trial).
  4. Newer antiplatelet drugs such as Prasugrel and Ticagrelor have been studied and are recommended in ACS.
- Statins:
  1. HMG-CoA reductase inhibitors (statins) (atorvastatin, rosuvastatin) with high-intensity therapy for a target LDL reduction of >50% if safely achieved in high-risk patients; if not a candidate for high-intensity therapy, patient should receive at least moderate-intensity statin therapy that lowers LDL by 30% to 50%. The initiation of

TABLE 4 ACCF/AHA Guidelines for Risk Factor Modification

Class	Indication	Level of Evidence
Lipid Management		
I (indicated)	1. Lifestyle modifications, including daily physical activity and weight management, are strongly recommended for all patients with SIHD.	B
	2. Dietary therapy for all patients should include reduced intake of saturated fats (to <7% of total calories), trans fatty acids (to <1% of total calories), and cholesterol (to <200 mg/day).	B
	3. In addition to therapeutic lifestyle changes, a moderate or high dose of a statin should be prescribed in the absence of contraindications or documented adverse effects.	A
IIa (good supportive evidence)	For patients who do not tolerate statins, LDL cholesterol–lowering therapy with bile acid sequestrants, niacin, or both is reasonable.	B
Blood Pressure Management		
I (indicated)	1. All patients should be counseled about the need for lifestyle modification: Weight control; increased physical activity; alcohol moderation; sodium reduction; and emphasis on increased consumption of fresh fruits, vegetables, and low-fat dairy products.	B
	2. In patients with SIHD and a BP of 140/90 mm Hg or higher, antihypertensive drug therapy should be instituted in addition to or after a trial of lifestyle modifications.	A
	3. The specific medications used for the treatment of high BP should be based on specific patient characteristics and may include ACE inhibitors and/or beta-blocking agents, as well as the addition of other drugs such as thiazide diuretics or calcium channel blocking agents if needed to achieve a goal BP of less than 140/90 mm Hg.	B
Diabetes Management		
IIa (good supportive evidence)	1. For selected individual patients, such as those with a short duration of diabetes mellitus and a long life expectancy, a goal hemoglobin A1c (HbA1c) of 7% or less is reasonable.	B
	2. A goal HbA1c between 7% and 9% is reasonable for certain patients according to age, history of hypoglycemia, presence of microvascular or macrovascular complications, or presence of coexisting medical conditions.	C
IIb (weak supportive evidence)	Initiation of pharmacotherapy interventions to achieve a target HbA1c might be reasonable.	A
III (not indicated)	Therapy with rosiglitazone should not be initiated in patients with SIHD.	C
Physical Activity		
I (indicated)	1. For all patients, clinicians should encourage 30 to 60 min of moderate-intensity aerobic activity at least 5 days and preferably 7 days per wk, supplemented by an increase in daily lifestyle activities (e.g., walking breaks at work, gardening, household work) to improve cardiorespiratory fitness and move patients out of the least-fit, least-active, high-risk cohort (bottom 20%).	B
	2. For all patients, risk assessment with a physical activity history and/or an exercise test is recommended to guide prognosis and prescription.	B
	3. Medically supervised programs (cardiac rehabilitation) and physician-directed, home-based programs are recommended for at-risk patients at first diagnosis.	A
IIa (good supportive evidence)	It is reasonable for clinicians to recommend complementary resistance training at least 2 days per wk.	C
Weight Management		
I (indicated)	1. BMI and/or waist circumference should be assessed at every visit, and clinicians should consistently encourage weight maintenance or reduction through an appropriate balance of lifestyle physical activity, structured exercise, caloric intake, and formal behavioral programs when indicated to maintain or achieve a BMI of between 18.5 and 24.9 kg/m^2 and a waist circumference of less than 102 cm (40 inches) in men and less than 88 cm (35 inches) in women (less for certain racial groups)	B
	2. The initial goal of weight loss therapy should be to reduce body weight by approximately 5% to 10% from baseline. With success, further weight loss can be attempted if indicated.	C
Smoking Cessation		
I (indicated)	Smoking cessation and avoidance of exposure to environmental tobacco smoke at work and home should be encouraged for all patients with SIHD. Follow-up, referral to special programs, and pharmacotherapy are recommended, as is a stepwise strategy for smoking cessation (Ask, Advise, Assess, Assist, Arrange, Avoid).	B
Management of Psychological Factors		
IIa (good supportive evidence)	It is reasonable to consider screening patients with SIHD for depression and to refer or treat when indicated.	B
IIb (weak supportive evidence)	Treatment of depression has not been shown to improve cardiovascular disease outcomes but might be reasonable for its other clinical benefits.	C
Alcohol Consumption		
IIb (weak supportive evidence)	In patients with SIHD who drink alcohol, it might be reasonable for nonpregnant women to have 1 drink (4 oz of wine, 12 oz of beer, or 1 oz of spirits) a day and for men to have 1 or 2 drinks a day unless alcohol is contraindicated (such as in patients with a history of alcohol abuse or dependence or those with liver disease).	C
Exposure to Air Pollution		
IIa (good supportive evidence)	It is reasonable for patients with SIHD to avoid exposure to increased air pollution to reduce their risk for cardiovascular events.	C

ACE, Angiotensin-converting enzyme; *ACCF/AHA,* American College of Cardiology Foundation/American Heart Association; *BMI,* body mass index; *BP,* blood pressure; *LDL,* low-density lipoprotein; *SIHD,* stable ischemic heart disease.

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

a statin can be determined by the ASCVD 10-yr risk calculator. Statins are recommended for primary prevention in patients with LDL >190, patients with type 2 diabetes mellitus (moderate intensity for ASCVD score <7.5% and high intensity for ASCVD risk score >7.5%), and patients with an elevated ASCVD risk score of >7.5%.

- PCSK9 inhibitors:
  1. This is a novel class of monoclonal antibodies that inhibit proprotein convertase subtilisin/kexin type 9. They cause dramatic reductions in LDL cholesterol and have been shown to reduce cardiovascular events. They are generally reserved for patients with familial hypercholesterolemia and patients with established vascular disease with LDL above goal despite maximal tolerated dose of statin. No overall mortality benefit has been demonstrated in studies to date.
- ACE-inhibitors (captopril, enalapril, lisinopril) are a class I recommendation for patients with chronic CAD with LV dysfunction LVEF <40% or diabetes and a class II recommendation for CAD patients without these features.

CORONARY ARTERY REVASCULARIZATION

- Patients with symptoms refractory to optimal medical therapy (OMT) as above or those with high clinical, stress testing, or an angiographic risk profile and suitable coronary anatomy may benefit from revascularization with either PCI (percutaneous coronary intervention) or CABG (coronary artery bypass graft) surgery. ACCF/AHA guidelines for

TABLE 5 ACCF/AHA Guidelines for Revascularization to Improve Survival Versus Medical Therapy in Patients with Stable Ischemic Heart Disease

Anatomic Setting	Class	Recommendation	Level of Evidence
Unprotected Left Main or Complex Coronary Artery Disease			
CABG and PCI	I	Heart team approach	C
CABG and PCI	IIa	Calculation of STS and SYNTAX Scores	B
Unprotected Left Main			
CABG	I		B
PCI	IIa	For SIHD when both of the following are present: 1. Anatomic conditions associated with a low risk for PCI procedural complications and a high likelihood of a good long-term outcome 2. Clinical characteristics that predict a significantly increased risk for adverse surgical outcomes	B
	IIb	For SIHD when both of the following are present: 1. Anatomic conditions associated with a low to intermediate risk for PCI procedural complications and an intermediate to high likelihood of a good long-term outcome 2. Clinical characteristics that predict increased risk for adverse surgical outcomes (e.g. STS-predicted operative mortality >2%)	B
	III	For SIHD in patients (versus performing CABG) with unfavorable anatomy for PCI and who are good candidates for CABG	B
Three-Vessel Coronary Artery Disease with or without Proximal Left Anterior Descending Coronary Artery Disease			
CABG	I		B
	IIa	It is reasonable to choose CABG over PCI in patients with complex 3-vessel CAD (e.g., SYNTAX score ≥22) who are good candidates for CABG	B
PCI	IIb		B
Two-Vessel Coronary Artery Disease with Proximal Left Anterior Descending Coronary Artery Disease			
CABG	I		B
PCI	IIb		B
Two-Vessel Coronary Artery Disease without Proximal Left Anterior Descending Coronary Artery Disease			
CABG	IIa	With extensive ischemia	B

TABLE 6 ACCF/AHA Guidelines for Revascularization to Improve Symptoms in Patients with Significant Anatomic (>50% Left Main or >70% Non–Left Main Coronary Artery Disease) or Physiologic (Fractional Flow Reserve <0.80) Coronary Artery Stenoses

Clinical Setting	Recommendation		Level of Evidence
≥1 significant stenosis amenable to revascularization and unacceptable angina despite GDMT	I	CABG or PCI	A
≥1 significant stenoses and unacceptable angina in whom GDMT cannot be implemented because of medication contraindications, adverse effects, or patient preferences	IIa	CABG or PCI	C
Previous CABG with ≥1 significant stenosis associated with ischemia and unacceptable angina despite GDMT	IIa	PCI	C
	IIb	CABG	C
Complex 3-vessel CAD (e.g., SYNTAX score ≥22) with or without involvement of the proximal LAD artery and a good candidate for CABG	IIa	CABG preferred over PCI	B
Viable ischemic myocardium that is perfused by coronary arteries that are not amenable to grafting	IIb	TMR as an adjunct to CABG	B
No anatomic or physiologic criteria for revascularization	III	CABG or PCI	C

ACCF/AHA, American College of Cardiology Foundation/American Heart Association; *CABG,* coronary artery bypass graft; *GDMT,* guideline-directed medical therapy; *LAD,* left anterior descending; *PCI,* percutaneous coronary intervention; *SYNTAX,* synergy between PCI with taxus and cardiac surgery; *TMR,* transmyocardial revascularization.
From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

revascularization are summarized in Tables 5 and 6.

- ACC/AHA class I indications for bypass surgery in chronic CAD patients include the following:
  1. High grade (>50%) left main CAD
  2. Left main CAD-equivalent anatomy including >70% luminal stenosis in the left anterior descending artery and left circumflex arteries
  3. Three-vessel disease with LVEF <50%
  4. Single- or two-vessel CAD with a large area of viable myocardium at risk
  5. Severe angina despite medical therapy if CABG can be performed with acceptable risk
- Percutaneous coronary intervention (PCI) has not been shown to reduce long-term rates of MI and death in patients with stable chronic CAD and therefore has no class I indications in this group. PCI is suitable in patients with suitable anatomy with refractory or lifestyle-limiting angina who have failed optimal medical therapy (OMT). Recent trials such as the COURAGE Trial have demonstrated no significant difference between OMT and PCI in overall survival, MI, and ACS over 5 yr in patients with chronic stable CAD.
- The SYNTAX trial, which used a numerical score based on qualitative plaque features on angiography, showed that surgical revascularization was associated with a lesser risk of stroke and major cardiac events if the SYNTAX score was high (>33).
- Trials continue to support CABG as superior to PCI in diabetic patients with multivessel CAD and should remain the revascularization strategy of choice in this patient population.

DISPOSITION

CAD is a common chronic condition with which many patients can live for years with good symptom control on optimal medical therapy.

REFERRAL

Cardiovascular disease specialist

PEARLS & CONSIDERATIONS

COMMENTS

- The transition from stable CAD to unstable angina must be carefully monitored. Symptoms of concern include more frequent episodes of chest pain, exertional dyspnea, chest pain that is less responsive to nitroglycerin, or first episode of chest pain. Regarding unstable angina, please refer to section on acute coronary syndromes.
- ACC/AHA guidelines for follow-up noninvasive testing are summarized in Tables 7 and 8.

Costochondritis (PTG)

BASIC INFORMATION

DEFINITION

Clinical condition characterized by pain and tenderness at costochondral or chondrosternal joints of the anterior chest wall without obvious swelling or induration.

SYNONYMS

Anterior chest wall syndrome
Chest wall pain syndrome
Costosternal syndrome
Parasternal chondrodynia

ICD-10CM CODE
M94.0 Chondrocostal junction syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Comprises approximately 28% of undifferentiated noncardiac chest pain patients
PREDOMINANT SEX: Women
PREDOMINANT AGE: >40 yr of age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

SYMPTOMS:

- Anterior chest wall pain, usually described as sharp, aching, or pressure-like. Pain is usually aggravated by coughing, sneezing, deep inspiration, or any chest wall movement.
- Pain is usually self-limited.
- May radiate to arms and shoulders mimicking cardiac chest pain.

SIGNS:

- Reproducible tenderness of costochondral (mostly second through fifth) or chondrosternal junction without localized swelling or induration is generally considered diagnostic for a chest wall syndrome.
- Various maneuvers can be utilized to reproduce chest wall pain, such as the "crowing rooster maneuver" (examiner stands behind the patient and exerts traction on the upper arms by pulling them backward and slightly superiorly) and horizontal arm flexion (the arm is flexed across the anterior chest while steady traction is applied in a horizontal direction).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Cardiac pain: Ischemic chest pain, acute pericarditis, aortic dissection
- Gastrointestinal: Gastroesophageal reflux disease
- Pulmonary: Pulmonary embolism, pneumonia, pneumothorax, pleurisy, malignancy
- Musculoskeletal (Table E1): Tietze syndrome, cervical or thoracic spine disease, arthritides
- Involvement of ribs by trauma, infections (*Candida albicans*), or neoplasms (breast cancer, prostate cancer, sarcoma, plasma cell cytoma, non-Hodgkin lymphoma)
- Miscellaneous: Fibromyalgia, panic attack

WORKUP

- A diagnosis of exclusion for chest pain after ruling out more serious conditions, including cardiac chest pain. Keys to diagnosis are a detailed history, a meticulous physical examination, and a few rationally selected diagnostic studies, including electrocardiogram and chest x-ray to rule out cardiopulmonary causes. Usefulness of nuclear scanning with technetium-99m scintigraphy, gallium, or bone scanning to assist diagnosis of costochondritis is not clear.

TREATMENT

ACUTE GENERAL Rx

- Often self-limiting, so reassurance is important.
- Symptomatic treatment includes local application of heat, minimizing activities that aggravate symptoms, stretching exercises for chest wall muscles, and nonsteroidal anti-inflammatory drugs or acetaminophen.
- Refractory cases can be treated with local injections of combined lidocaine and corticosteroid (may be a useful diagnostic and therapeutic tool). Dry needling by a trained physical therapist may be helpful.
- Recurrent costochondritis may respond to sulfasalazine; however, there is minimal evidence and no clinical trials of pharmacologic therapy for costochondritis.

PEARLS & CONSIDERATIONS

Presence of costochondritis in a patient with chest pain does not exclude more serious problems including cardiac pain. Further testing is required as clinically indicated.

RELATED CONTENT

Costochondritis (Patient Information)

AUTHOR: **Asha Shrestha, MD**

TABLE E1 Musculoskeletal Chest Pain

Disorder	Clinical Features	Comments
Tietze syndrome	Painful swelling of usually second or third costochondral junctions.	Less common than costochondritis; commonly affects young people of either sex. Exact cause is unknown, but a traumatic pathogenesis has been associated. The disease course is mostly self-limited. Non-Hodgkin lymphoma of medial clavicular head has been reported to mimic Tietze syndrome.
Slipping rib syndrome	Pain at the lower costal cartilages, associated with increased mobility of the anterior end of costal cartilage. Most commonly affects 10th rib and occasionally affects 8th and 9th ribs.	Maneuver such as hooking the fingers under the anterior costal margin and pulling the rib cage anteriorly may produce a palpable click of the cartilages slipping over one another.
Cervical, thoracic disc disease	Referred regional pain from affected areas. Often aggravated by spine motion and may be accompanied by radicular pain into arm if cervical origin or along intercostal nerve if thoracic origin. Symptoms are reproduced by Spurling maneuver (steady pressure to head causing increased axial loading on the nerve root).	May mimic chest disease if spinal complaints are minimal and referred or radicular symptoms predominate.
Sternoclavicular or manubriosternal joint involvement in osteoarthritis, inflammatory conditions (rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, relapsing polychondritis), and infection	Dull, aching local pain with tenderness. Occasional bony joint enlargement with soft tissue swelling.	Crepitus may rarely be present.

Craniopharyngioma PTG ALG

BASIC INFORMATION

DEFINITION

Craniopharyngiomas are tumors arising from squamous cell remnants of Rathke pouch, located in the infundibulum or upper anterior hypophysis.

SYNONYM

Subset of nonadenomatous pituitary tumors

ICD-10CM CODE

D44.3 Neoplasm of uncertain behavior of pituitary gland

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Occurs at all ages; peak during the first two decades of life, with a second small peak occurring in the sixth decade

PREDOMINANT SEX:

- Both sexes are usually equally affected.
- Craniopharyngiomas are the most common nonglial tumors in children and account for 3% to 5% of all pediatric brain tumors.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The typical onset is insidious and a 1- to 2-yr history of slowly progressive symptoms is common.
- Presenting symptoms are usually related to the effects of a sella turcica mass. Approximately 75% of patients report headache and have visual disturbances.
- The usual visual defect is bitemporal hemianopsia. Optic nerve involvement with decreased visual acuity and scotomas and homonymous hemianopsia from optic tract involvement may also occur.
- Other symptoms include mental changes, nausea, vomiting, somnolence, or symptoms of pituitary failure. In adults, sexual dysfunction is the most common endocrine complaint, with impotence in men and primary or secondary amenorrhea in women. Diabetes insipidus is found in 25% of cases. In children, craniopharyngiomas may present with dwarfism.
- More than 70% of children at the time of diagnosis present with growth hormone deficiency, obstructive hydrocephalus, short-term memory deficits, and psychomotor slowing.

ETIOLOGY

Craniopharyngiomas are believed to arise from nests of squamous epithelial cells that are commonly found in the suprasellar area surrounding the pars tuberalis of the adult pituitary.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pituitary adenoma
- Empty sella syndrome
- Pituitary failure of any cause
- Primary brain tumors (e.g., meningiomas, astrocytomas)
- Metastatic brain tumors
- Other brain tumors
- Cerebral aneurysm

LABORATORY TESTS

- Hypothyroidism (low FT_4, FT_3 with high thyroid-stimulating hormone).
- Hypercortisolism (low cortisol) with low adrenocorticotropic hormone.
- Low sex hormones (testosterone, estriol) with low follicle-stimulating hormone and luteinizing hormone.
- Diabetes insipidus (hypernatremia, low urine osmolarity, high plasma osmolarity).
- Prolactin may be normal or slightly elevated.
- Pituitary stimulation tests may be required in some cases.

IMAGING STUDIES

- MRI (Fig. E1) or head CT if MRI is contraindicated. MRI features include a multicystic and solid enhancing suprasellar mass. Hydrocephalus may also be present if the mass is large. CT usually reveals intratumoral calcifications.
- Visual field testing for bitemporal hemianopsia.
- Skull film may show:
  1. Enlarged or eroded sella turcica (50%).
  2. Suprasellar calcification (50%).

TREATMENT

GENERAL Rx

- Traditionally, surgery has been the main treatment for craniopharyngioma. However, radiation treatment instead of surgery may be an option in selected cases.
- Surgical resection (curative or palliative):
  1. Transsphenoidal surgery for small intrasellar tumors.
  2. Subfrontal craniotomy for most patients.
- Overall prognosis is good with 80% to 90% chance of permanent cure.
- Postoperative radiation.
- Intralesional ^{32}P irradiation or bleomycin for unresectable tumors. Long-term complications of radiation include secondary malignancies, optic neuropathy, and vascular injury.

PROGNOSIS

- Overall prognosis is good with 80% to 90% chance of permanent cure.
- Operative mortality rate: 3% to 16% (higher with large tumors).
- Postoperative recurrence rate: <20% of cases after total resection and 60% of cases after subtotal resection. Most recurrences occur within the first 2 yr after surgery.
- 5-yr and 10-yr survival: 88% and 76%, respectively, with surgery and radiation.
- The most important factors that correlate with prognosis are the extent of resection and postoperative radiation.
- Long-term posttreatment hormonal, visual, and neurologic problems occur in a significant percentage of patients.

Craniopharyngioma (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

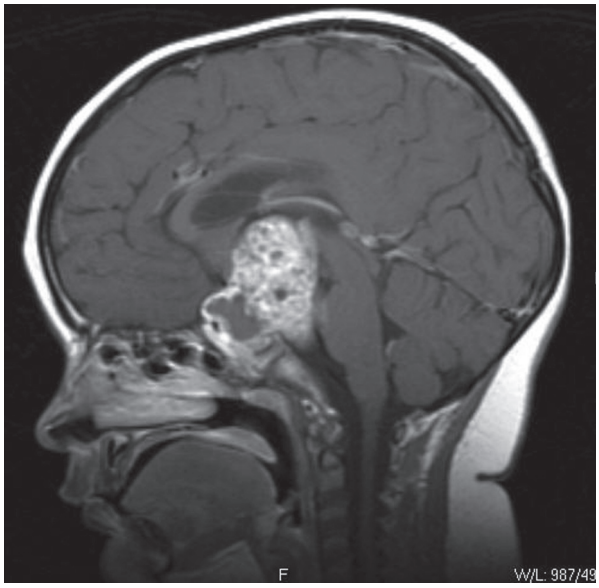

FIG. E1 Craniopharyngioma. Magnetic resonance imaging (MRI)—Note the heterogeneous nature (solid > cystic) of this craniopharyngioma on MRI with significant suprasellar extension. Despite its location, potentially obstructing the foramen of Monro, there was no hydrocephalus. (Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice,* ed 6, Philadelphia, 2017, Elsevier.)

BASIC INFORMATION

DEFINITION

Creutzfeldt-Jakob disease (CJD) is a progressive, fatal, dementing neurologic illness caused by an infectious protein agent known as a *prion.*

SYNONYMS

Transmissible spongiform encephalopathy
Prion disease
CJD

OTHER PRION DISEASES

Fatal familial insomnia
Gerstmann-Sträussler-Scheinker syndrome (GSS)
Bovine spongiform encephalopathy ("mad cow" disease)
Kuru

ICD-10CM CODE
A81.00 Creutzfeldt-Jakob disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence of 1 per 1 million population per yr.
- Peak age 60 yr (range, 16 to 82 yr); whereas sporadic cases are seen in an older population, the variant subtype is commonly seen in younger patients.
- Most common cause of rapidly progressive dementia, with a disease duration of less than 1 yr until death.
- 5% to 10% familial; remaining cases are sporadic; iatrogenic cases (corneal or liver transplants, dura mater allograft, human pituitary extract, blood or blood product transfusion, reused medical equipment such as electroencephalogram [EEG] depth electrodes) are very rare—about 1%; variant CJD is caused by ingestion of meat from cows with prion disease and is more commonly seen in Great Britain, but cases from Canada, France, Saudi Arabia, and the U.S. have also been reported.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cognitive deficits: Patients present with cognitive deficits (dementing illness—memory loss, behavioral abnormalities, higher cortical function impairment), usually a subacute rapid progressive encephalopathy or dementia. Prodromal symptoms such as fatigue, depression, weight loss, and disorders of sleep and appetite may be seen in about one third of patients. Early stages are characterized by confusion with hallucinations, delusions, and agitation.
- More than 80% will have myoclonus—generalized and exaggerated by startle.
- Pyramidal tract signs (weakness), cerebellar signs (clumsiness), and extrapyramidal signs (parkinsonian features) are seen in more than 50% of the cases.
- Less common features include cortical visual abnormalities, abnormal eye movements, vestibular dysfunction, sensory disturbances, autonomic dysfunction, lower motor neuron signs, and seizures.

ETIOLOGY

Small proteinaceous infectious particle (prion): Noninfectious prion protein (PrP) is a cellular protein found on the surfaces of neurons. Normal function is not known. This normal protein is converted to a protease-resistant infectious agent by the infectious prion protein.

- Normal prion protein *(PRNP)* gene is found on human chromosome 20.
- Methionine and valine distribution on codon 129 of the PRNP determines the six clinical phenotypes of CJD.

DIAGNOSIS

- Definite CJD: Neuropathologically confirmed spongiform encephalopathy in a case of progressive dementia
- Probable CJD: History of rapidly progressive dementia (<2 yr) with typical EEG and with at least two of the following clinical features: myoclonus, visual or cerebellar dysfunction, pyramidal or extrapyramidal features, akinetic mutism
- Possible CJD: Same as probable CJD without EEG findings

DIFFERENTIAL DIAGNOSIS

- Other progressive dementias (Alzheimer disease, frontotemporal dementia, Lewy body dementia, and vascular dementia)
- Infectious (viral, HIV, fungal, TB, Whipple disease)
- Inflammatory or autoimmune (CNS vasculitis, autoimmune encephalitis, Hashimoto encephalopathy, subacute sclerosing panencephalitis [SSPE])
- Metabolic (vitamin deficiency, endocrine)
- Cancers (CNS lymphoma, gliomatosis cerebri, paraneoplastic encephalitis)
- Other conditions, toxic (heavy metal poisoning)

A clinical algorithm for the evaluation of dementia is described in Section III, "Dementia."

WORKUP

- Evaluate for treatable causes of dementia (see section on "Alzheimer Disease").
- Brain biopsy is gold standard for diagnosis but may not be performed because there is no treatment or cure, and there is the potential risk of iatrogenic spread.
- Lumbar puncture with spinal fluid analysis for presence of 14-3-3 protein or human prion protein (PrP^{Sc}).
- Recent guidelines issued by the American Academy of Neurology states that clinicians should order assays for 14-3-3 in patients with rapidly progressive dementia, strong suspicion of sporadic CJD, and an uncertain diagnosis (pretest probability of 20% to 90%). The test has a high false-positive and false-negative rate because of its presence in other chronic noninflammatory dementing diseases.

LABORATORY TESTS

- Presence of periodic sharp wave complexes on EEG in cases of rapidly progressive dementia has a sensitivity of 67% and a specificity of 86%.
- In cases of probable or possible CJD, presence of the 14-3-3 protein in CSF has a 95% positive predictive value with its absence having a 92% negative predictive value. Test for presence of human prion protein (PrP^{Sc}) in CSF has been reported to be 83% sensitive and 100% specific. Repeated testing for 14-3-3 protein increases the probability of a positive result. Enolase and neopterin in CSF are the other nonspecific markers that may have adjunct diagnostic value.
- Recent reports indicate that testing of nasal brushings using RT-QuIC, an ultrasensitive, multiwall plate–based fluorescence assay involving PrP^{CJD}–seeded polymerization of recombinant PrP into amyloid fibrils, is accurate in diagnosing CJD.
- PRP^{Sc} can also be detected in urine samples obtained from patients with variant CJD.
- The National Prion Disease Pathology Surveillance Center at Case Western Reserve University performs specific diagnostic tests free of charge and acts as a reporting center to the CDC.

IMAGING STUDIES

MRI scan is one of the most sensitive diagnostic tools for CJD. It can show areas of restricted diffusion in the basal ganglia and/or cerebral cortex. MRI diffusion-weighted imaging has a sensitivity of 92.3% and a specificity of 93.8% in cases of rapidly progressive dementia. T2-weighted imaging may also show subtle hyperintensities in the lenticular nuclei in about 82% of cases.

TREATMENT

NONPHARMACOLOGIC THERAPY

Full-time caregiver or nursing home: Social work can be helpful with end-of-life discussions, family counseling, and optimizing appropriate home services. Proper disposal of medical equipment and avoidance of organ transplants from these patients prevent transmission of the disease.

ACUTE GENERAL Rx

No known therapy

CHRONIC Rx

No known therapy

DISPOSITION

The disease is fatal. Mean duration of illness is 8 mo (range, 1 to 130 mo). One in 7 survives to 1 yr, and 1 in 30 survives to 2 yr. Better survival found in younger age at onset of disease and female gender. Increased survival may be falsely reported due to coexisting dementias such as Alzheimer disease with earlier onset of dementia than CJD.

REFERRAL

- Neurology for evaluation of any rapidly progressive dementia
- Social work

PEARLS & CONSIDERATIONS

COMMENTS

- A diagnosis of CJD should be considered in patients with rapid progression of dementia from unknown causes.
- Exposure to human or animal nervous tissues increases the odds of CJD in patients presenting with progressive dementia.
- Related diseases in human beings: Kuru, fatal familial insomnia, Gerstmann-Sträussler-Scheinker syndrome, new-variant CJD.
- Related diseases in animals: Scrapie, bovine spongiform encephalopathy (mad cow disease).

Crohn Disease PTG

BASIC INFORMATION

DEFINITION

Crohn disease (CD) is an inflammatory disease of the bowel of unknown etiology, most commonly involving the terminal ileum and manifesting primarily with diarrhea, abdominal pain, fatigue, and weight loss.

SYNONYMS

CD
Regional enteritis
Inflammatory bowel disease (IBD)

ICD-10CM CODES

K50.00	Crohn disease of small intestine without complications
K50.011	Crohn disease of small intestine with rectal bleeding
K50.012	Crohn disease of small intestine with intestinal obstruction
K50.013	Crohn disease of small intestine with fistula
K50.014	Crohn disease of small intestine with abscess
K50.018	Crohn disease of small intestine with other complication
K50.019	Crohn disease of small intestine with unspecified complications
K50.10	Crohn disease of large intestine without complications
K50.111	Crohn disease of large intestine with rectal bleeding
K50.112	Crohn disease of large intestine with intestinal obstruction
K50.113	Crohn disease of large intestine with fistula
K50.114	Crohn disease of large intestine with abscess
K50.118	Crohn disease of large intestine with other complication
K50.119	Crohn disease of large intestine with unspecified complications
K50.80	Crohn disease of both small and large intestine without complications
K50.811	Crohn disease of both small and large intestine with rectal bleeding
K50.812	Crohn disease of both small and large intestine with intestinal obstruction
K50.813	Crohn disease of both small and large intestine with fistula
K50.814	Crohn disease of both small and large intestine with abscess
K50.818	Crohn disease of both small and large intestine with other complication
K50.819	Crohn disease of both small and large intestine with unspecified complications
K50.90	Crohn disease, unspecified, without complications
K50.911	Crohn disease, unspecified, with rectal bleeding
K50.912	Crohn disease, unspecified, with intestinal obstruction
K50.913	Crohn disease, unspecified, with fistula
K50.914	Crohn disease, unspecified, with abscess
K50.918	Crohn disease, unspecified, with other complication
K50.919	Crohn disease, unspecified, with unspecified complications

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Annual incidence ranges from 3 to 20 cases per 100,000.
- Median age of onset is 30 yr.
- Crohn disease has 2 peaks, the first between age 20 and 30 yr and the second a smaller peak around 50 yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical exam findings vary depending on disease location and severity
- Abdominal tenderness, mass, or distention
- Chronic or nocturnal diarrhea
- Weight loss, fever, night sweats
- Hyperactive bowel sounds in patients with partial obstruction, bloody diarrhea
- Delayed growth and failure of normal development in children
- Perianal and rectal abscesses, multiple sinuses and scarring (Fig. E1), mouth ulcers, cobblestone appearance of oral mucosa (Fig. E2), and atrophic glossitis
- Extraintestinal manifestations (Table E1): Joint swelling and tenderness, hepatosplenomegaly, erythema nodosum, clubbing, tenderness to palpation of the sacroiliac joints
- Symptoms may be intermittent, with varying periods of remission
- Overall 45% to 50% of patients have ileocolonic inflammation, 30% have isolated small bowel disease, 20% have isolated colonic disease, and 5% have isolated upper GI or perianal manifestations

ETIOLOGY

Unknown. Pathophysiologically, Crohn disease involves an immune system dysfunction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ulcerative colitis (see Table 2)
- Infectious diseases (tuberculosis, *Yersinia, Salmonella, Shigella, Campylobacter*)
- Parasitic infections (amebic infection)
- Pseudomembranous colitis
- Ischemic colitis in elderly patients
- Lymphoma
- Colon carcinoma
- Diverticulitis
- Radiation enteritis
- Collagenous colitis
- Fungal infections (*Histoplasma, Actinomyces*)
- Anorectal and colon diseases, formerly referred to as gay bowel syndrome
- Carcinoid tumors
- Celiac sprue
- Mesenteric adenitis

LABORATORY TESTS

- Decreased hemoglobin and hematocrit from chronic blood loss, effect of inflammation on bone marrow, and malabsorption of vitamin B_{12}
- Hypokalemia, hypomagnesemia, hypocalcemia, and low albumin in patients with chronic diarrhea
- Vitamin B_{12} and folate deficiency
- Elevated erythrocyte sedimentation rate and CRP
- Positive anti–*Saccharomyces cerevisiae* antibodies
- Elevated INR (due to vitamin K malabsorption)
- Fecal calprotectin has been reported as useful in screening of patients with suspected IBD. Based on a pretest probability of 32% in adults, an abnormal calprotectin test result increases the posttest probability to 91%, and a normal result reduces the probability of IBD to 3%. False elevations may occur with other gastrointestinal diseases such as bacterial, viral, and protozoal causes of infective diarrhea

TABLE 2 Differentiating Features

	Ulcerative Colitis	Crohn Disease
Site of involvement	Only involves colon Rectum almost always involved	Any area of the gastrointestinal tract Rectum usually spared
Pattern of involvement	Continuous	Skip lesions
Diarrhea	Bloody	Usually nonbloody
Severe abdominal pain	Rare	Frequent
Perianal disease	No	In 30% of patients
Fistula	No	Yes
Endoscopic findings	Erythematous and friable Superficial ulceration	Aphthoid and deep ulcers Cobblestoning
Radiologic findings	Tubular appearance resulting from loss of haustral folds	String sign of terminal ileum RLQ mass, fistulas, abscesses
Histologic features	Mucosa only Crypt abscesses	Transmural crypt abscesses, granulomas (about 30%)
Smoking	Protective	Worsens course
Serology	p-ANCA more common	ASCA more common

ASCA, Anti–*Saccharomyces cerevisiae* antibodies; *p-ANCA,* perinuclear antineutrophil cytoplasmic antibody; *RLQ,* right lower quadrant.
From Andreoli TE et al: *Andreoli and Carpenter's Cecil essentials of medicine,* ed 8, Philadelphia, 2010, Saunders.

ENDOSCOPIC EVALUATION

Endoscopic features of Crohn disease include asymmetric and discontinued disease, deep longitudinal fissures, cobblestone appearance, and presence of strictures (Fig. E3). Crypt distortion and inflammation are also present. Granulomas may be present.

IMAGING STUDIES

- CT of abdomen may show thickening of the terminal ileum and is helpful in identifying abscesses, fistulas (Fig. E4), and other complications.
- Magnetic resonance enterography (MRe) is superior to other imaging modalities in its ability to distinguish active from chronic fibrotic disease. It is, however, more expensive.
- In 10% to 15% of patients with IBD, a clear distinction between ulcerative colitis and Crohn disease cannot be made. In general, Crohn disease can be distinguished from ulcerative colitis by the presence of transmural involvement and the frequent presence of noncaseating granulomas and lymphoid aggregates on biopsy.

Rx TREATMENT

The medical management of Crohn disease is based on disease activity. According to Hanauer and Sanborn, disease activity can be defined as follows:

- Mild to moderate disease: The patient is ambulatory and able to take oral alimentation. There is no dehydration, high fever, abdominal tenderness, painful mass, obstruction, or weight loss of >10%.
- Moderate to severe disease: Either the patient has not responded to treatment for mild to moderate disease or has more pronounced symptoms, including fever, significant weight loss, abdominal pain or tenderness, intermittent nausea and vomiting, or significant anemia.
- Severe fulminant disease: Either the patient has persistent symptoms despite outpatient steroid therapy or has high fever, persistent vomiting, evidence of intestinal obstruction, rebound tenderness, cachexia, or evidence of an abscess.
- Remission: The patient is asymptomatic or without inflammatory sequelae, including patients responding to acute medical intervention.

NONPHARMACOLOGIC THERAPY

- Nutritional supplementation is needed in patients with advanced disease. Total parenteral nutrition may be necessary in selected patients.
- Low-residue diet is necessary when obstructive symptoms are present.
- If diarrhea is prominent, increased dietary fiber and decreased fat in the diet are sometimes helpful.
- Psychotherapy is useful for situational adjustment crises. A trusting and mutually understanding relationship and referral to self-help groups are very important because of the chronicity of the disease and the relatively young age of the patients.
- Avoid oral feedings during acute exacerbation to decrease colonic activity: A low-roughage diet may be helpful in early relapse.

ACUTE GENERAL Rx

- Corticosteroids are used to induce remission. They have been the mainstay for treating moderate to severe active Crohn disease. Prednisone 40 to 60 mg/day is useful for acute exacerbation. Steroids are usually tapered over approximately 2 to 3 mo. Some patients require a low dose for a prolonged period of maintenance.
- Steroid analogues are locally active corticosteroids that target specific areas of inflammation in the gastrointestinal tract. Budesonide is available as a controlled-release formulation and is approved for mild to moderate active Crohn disease involving the ileum and/or ascending colon. The adult dose is 9 mg qd for a maximum of 8 wk.
- Patients responding to glucocorticoids are transitioned to immunomodulators as their glucocorticoid is tapered.
- Immunosuppressants such as azathioprine or mercaptopurine are used for maintenance of remission. Methotrexate is an alternative agent.
- Metronidazole 500 mg qid may be useful for colonic fistulas and treatment of mild to moderate active Crohn disease. Ciprofloxacin 1 g qd has also been found to be effective in decreasing disease activity.
- TNF inhibitors are agents useful to induce remission and maintain remission in patients with moderate to severe Crohn disease. Infliximab, a chimeric monoclonal antibody targeting tumor necrosis factor-α, is effective in the treatment of enterocutaneous fistulas. This medication can induce clinical improvement in 80% of patients with Crohn disease refractory to other agents. It can be used in combination with other medications such as azathioprine in patients with severe Crohn disease. A PPD test should be done before using this medication. Adalimumab and certolizumab are other TNF inhibitors also effective in inducing remissions and may be useful in adult patients with Crohn disease who cannot tolerate infliximab or have symptoms despite receiving infliximab therapy. Efficacy is better when an anti-TNF is used together with an immunomodulator.
- Natalizumab, a selective adhesion-molecule inhibitor, has been reported to be effective in increasing the rate of remission and response in patients with active Crohn disease. It is effective for patients in whom anti-TNF therapy has been unsuccessful. Prior to using natalizumab, serologic testing should be done for JC virus, which causes multifocal leukoencephalopathy (PML), and if the patient is seronegative, the risk of PML from natalizumab is low. Vedolizumab is another IV integrin receptor antagonist recently FDA approved for moderate to severe Crohn disease patients who have not responded to or cannot tolerate standard treatment. Vedolizumab use is not associated with high risk of PML. Ustekinumab, a monoclonal antibody to the P_40 subunit of interleukin-12 and interleukin-23, has shown efficacy for induction and maintenance therapy for Crohn disease. It has been FDA-approved for moderate to severely active Crohn disease unresponsive to immunomodulators or corticosteroids or a tumor necrosis factor inhibitor.
- Hydrocortisone enema bid or tid is useful for proctitis.
- Most patients who have anemia associated with Crohn disease respond to iron supplementation. Erythropoietin is useful in patients with anemia refractory to treatment with iron and vitamins.

CHRONIC Rx

- Monitor disease activity with symptom review and laboratory evaluation (complete blood count and sedimentation rate).
- Liver tests and vitamin B_{12} levels monitored on a yearly basis.

DISPOSITION

There is no cure for CD, and most patients require at least one surgical resection. One tenth of patients have prolonged remission, three quarters have a chronic intermittent disease course, and one eighth have an unremitting course. Patients with IBD are at increased risk of colon cancer.

REFERRAL

Surgical referral is needed for complications such as abscess formation, obstruction, fistulas, toxic megacolon, refractory disease, or severe hemorrhage. Approximately 40% to 50% of patients will require some type of bowel surgery within the first 5 yr of Crohn disease. A conservative surgical approach is necessary because surgery is not curative. Multiple surgeries may also result in short bowel syndrome.

FIG. E1 Crohn disease affecting the skin of the buttocks, with multiple sinuses and scarring. This patient had a lesion of pyoderma gangrenosum when first seen and developed inflammatory plaques with the appearance of Sweet disease on the trunk (with the novel feature of a Koebner reaction into recent scars). (From White GM, Cox NH [eds]: *Diseases of the skin: a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

FIG. E2 Crohn disease of the oral mucosa. In this fairly quiescent example, there is a granular cobblestoned appearance. Some patients have more aggressive fissured and ulcerated plaque lesions. (From White GM, Cox NH [eds]: *Diseases of the skin: a color atlas and text,* ed 2, St Louis, 2006, Mosby.)

TABLE E1 Extraintestinal Manifestations of Inflammatory Bowel Disease

Feature or Disease	Crohn	Ulcerative Colitis
Peripheral arthritis	~15%	~10%
Axial or sacroiliac arthritis	~15%-20%	~10%-15%
Septic arthritis	Rare	Not reported
Skin		
Erythema nodosum	Up to 15%	<15%
Erythema multiforme	Rare	?
Pyoderma gangrenosum	0.5%-2%	0.3%-0.4% in severe disease
Aphthous ulcers	Rare	1%-8%
Nephrolithiasis (oxalate)	<15%	?
Amyloidosis	Very rare	Not reported
Liver disease	3%-5%	7%
Uveitis	13%	4%
Vasculitis	Takayasu	<5%
Clubbing of fingers	Yes	1%-5%
Increased prevalence of asthma	Yes	Yes
Increased prevalence of multiple sclerosis	No	Yes

From Firestein GS et al: *Kelly's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.

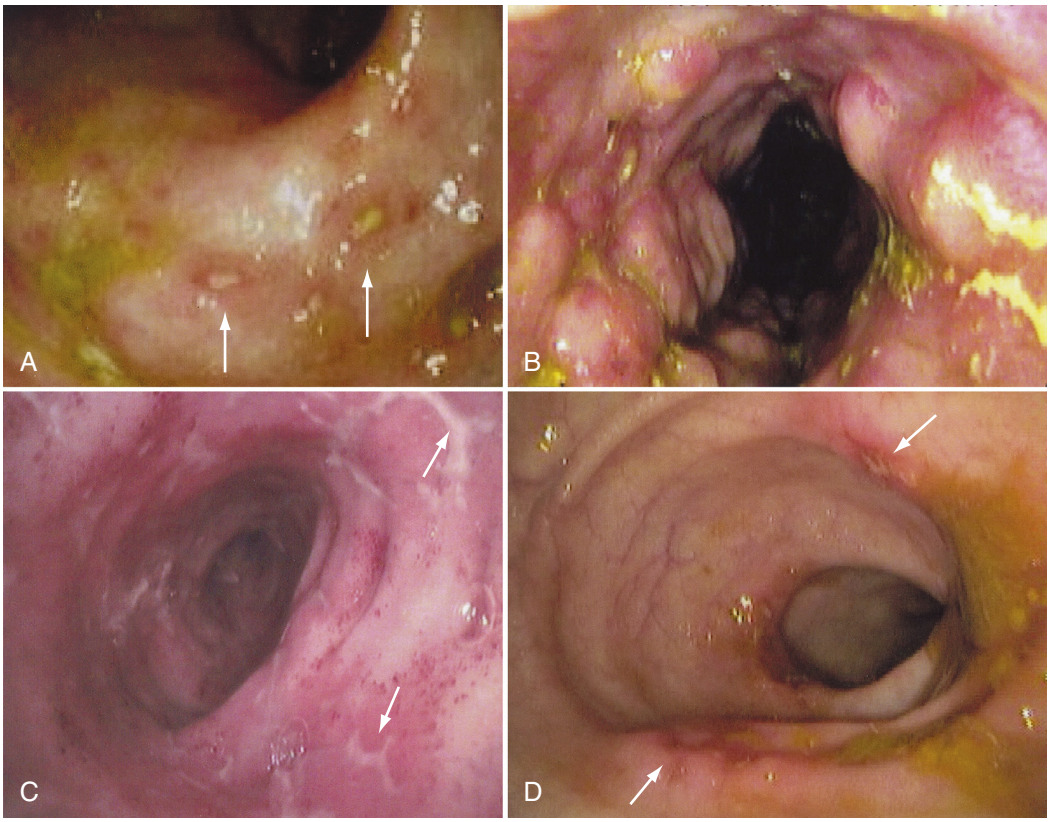

FIG. E3 Endoscopic appearance of Crohn disease. A wide variety of findings may be visualized on endoscopy, in part depending on the duration and severity of the inflammation. **A,** Typical aphthous ulcers *(arrows)* consisting of a central white depression surrounded by a slightly elevated, erythematous rim only a few millimeters in diameter. **B,** Findings more typical of advanced disease, with erythema, edema, and a cobblestone appearance. **C,** Stellate ulcers *(arrows)* in the terminal ileum. **D,** Discrete ulcers *(arrows)* with normal intervening mucosa typical of the patchy inflammation seen in Crohn disease. (From Feldman M et al: *Sleisenger and Fortran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

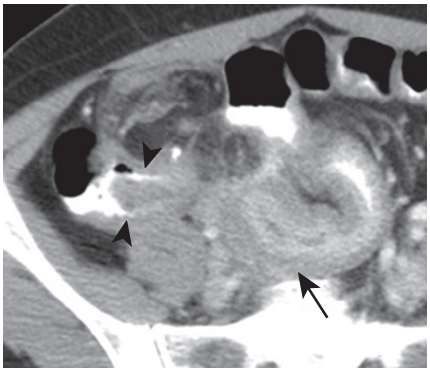

FIG. E4 Crohn disease: Fistulas. The ileum *(arrow)* in the right lower quadrant exhibits marked wall thickening and matting of bowel loops caused by inflammation of the mesentery. A double-tract bowel lumen *(arrowheads)* is seen, indicating the formation of an ileo–ileal fistula. (From Webb WR, Brant WE, Major NM: *Fundamentals of body CT,* ed 4, Philadelphia, 2015, Saunders.)

BASIC INFORMATION

DEFINITION

Acute laryngotracheobronchitis is a viral infection of the upper and lower respiratory tract leading to erythema and edema of the tracheal walls and narrowing of the subglottic region. Laryngotracheitis, which is limited to larynx and trachea, is also known as croup.

SYNONYM

Laryngotracheobronchitis

ICD-10CM CODE
J05.0 Acute obstructive laryngitis [croup]

EPIDEMIOLOGY & DEMOGRAPHICS

- Croup is primarily a disease of children occurring between the ages of 1 and 6 yr.
- The peak incidence of croup is between 6 and 36 mo.
- Most cases occur in the fall and represent parainfluenza type 1 viral infection.
- Winter outbreaks usually represent infection by influenza A and B viruses. Fig. E1 illustrates the seasonal occurrence of croup cases in relation to the epidemiologic activity of the respiratory viruses associated with croup.
- Croup accounts for 10% to 15% of lower respiratory tract infections in young children.
- Boys are affected more often than girls at a ratio of 1.4:1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Most children with croup present with symptoms of an upper respiratory infection for several days (Fig. E2):

- Rhinorrhea
- Cough
- Low-grade fever
- Barking cough that usually occurs at night and awakens the child
- Sore throat
- Stridor
- Apprehension
- Use of accessory muscles of respiration
- Tachypnea
- Tachycardia
- Wheezing

ETIOLOGY

- Parainfluenza viruses (types 1, 2, and 3) are the most common causes of croup in the United States.
- Type 1 is the most common cause of fall and winter outbreaks, with type 2 causing milder disease outbreaks. Parainfluenza type 3, although sporadic, can be more severe than other types.
- Respiratory syncytial virus (RSV) and adenovirus are common causes of croup as well.
- Human coronavirus NL63, rhinoviruses, enteroviruses such as Coxsackie and echovirus.
- Influenza A and B, although not common causes of croup, do lead to more severe cases of the disease.
- *Mycoplasma pneumoniae* (rare).

DIAGNOSIS

The diagnosis of croup is usually based on the characteristic clinical presentation of a young child between the ages of 1 and 6 yr waking up with a barking cough ("seal's bark") and stridor.

DIFFERENTIAL DIAGNOSIS

- Spasmodic croup
- Epiglottitis
- Bacterial tracheitis
- Angioneurotic edema
- Diphtheria
- Peritonsillar abscess
- Retropharyngeal abscess
- Smoke inhalation
- Foreign body

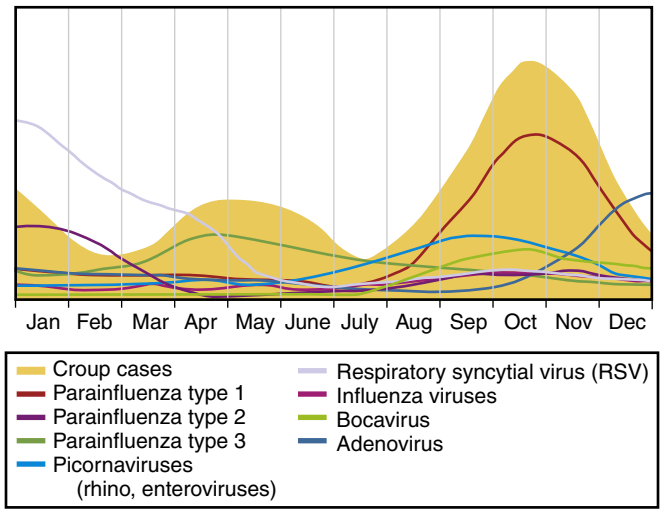

FIG. E1 The seasonal occurrence of croup cases is shown in relation to the epidemiologic activity of the respiratory viruses associated with croup. The major seasons of croup cases in temperate climates occur from fall to winter every other year, when outbreaks of parainfluenza type 1 virus occur, and from spring to summer, when parainfluenza type 3 is prominent. Influenza and respiratory syncytial virus are epidemic during winter to spring but contribute small proportions of cases. The picornaviruses, adenovirus, coronaviruses, and bocavirus are present through many months of the year. (From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

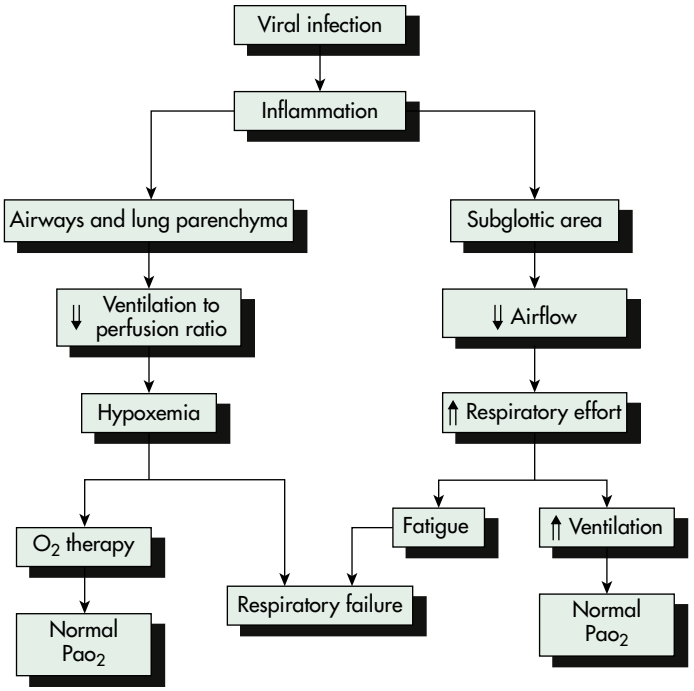

FIG. E2 Physiologic abnormalities in croup. O_2, Oxygen; Pao_2, partial pressure of oxygen in arterial blood. (From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.)

TABLE E1 Characteristics of Laryngotracheobronchitis, Bacterial Tracheitis, and Epiglottitis

	Laryngotracheobronchitis	Bacterial Tracheitis	Epiglottitis
Age	3 mo to 3 yr	6 mo to 12 yr	12 yr (average)
Onset	Gradual	Intermediate	<24 hr
Fever	Usually low	Usually high	High
Cough	Characteristic "barking"	Characteristic "barking"	None
Sore throat	None	Usually absent	Often severe
Drooling	No	No	Usually
Posture	Any position	Any position	Sitting forward, mouth open, drooling
Voice	Normal	Normal or hoarse	Muffled
Appearance	Nontoxic	Toxic	Toxic
Seasonal distribution	Usually winter, epidemic	Throughout the year	Throughout the year

From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, Saunders.

WORKUP

- The workup of a child with croup is to differentiate viral laryngotracheobronchitis from noninfectious causes of stridor, bacterial tracheitis, and epiglottitis caused by *H. influenzae* (Table E1).
- The clinical presentation and plain films of the soft tissues of the neck assist in differentiating viral from nonviral and noninfectious causes.

LABORATORY TESTS

- Laboratory tests are not often used to make the diagnosis of viral tracheobronchitis.
- CBC, viral antibody serology panels, and tissue cultures can be ordered and may detect the infecting agent in up to 65% of cases.
- Pulse oximetry and arterial blood gas (ABG) determination for patients with tachypnea and respiratory distress.

IMAGING STUDIES

- Plain (anteroposterior and lateral) films of the soft tissues of the neck (Fig. E3) may show the classic radiographic finding of subglottic stenosis or "steeple" sign.
- CT scan of the soft tissues of the neck may be performed in cases in which the differentiation between croup, epiglottitis, and noninfectious causes is more difficult.
- Direct visualization via laryngoscopy may be useful in some situations under a controlled setting.

Rx TREATMENT

Treatment of croup focuses on airway management. Table E2 summarizes the evaluation and management of children with croup.

NONPHARMACOLOGIC THERAPY

- Humidified oxygen or humidified air
- Cool mist
- Hot steam

ACUTE GENERAL Rx

- 0.25 to 0.75 ml of 2.25% racemic epinephrine every 20 min is used in children with severe respiratory symptoms, rest stridor, and impending intubation.
- Corticosteroids (e.g., dexamethasone 0.6 mg/kg IV or PO, prednisone 2 mg/kg/day) have been shown to be effective.
- Budesonide, a nebulized corticosteroid given at 4 mg, has been shown to improve symptoms in patients with moderate to severe croup.

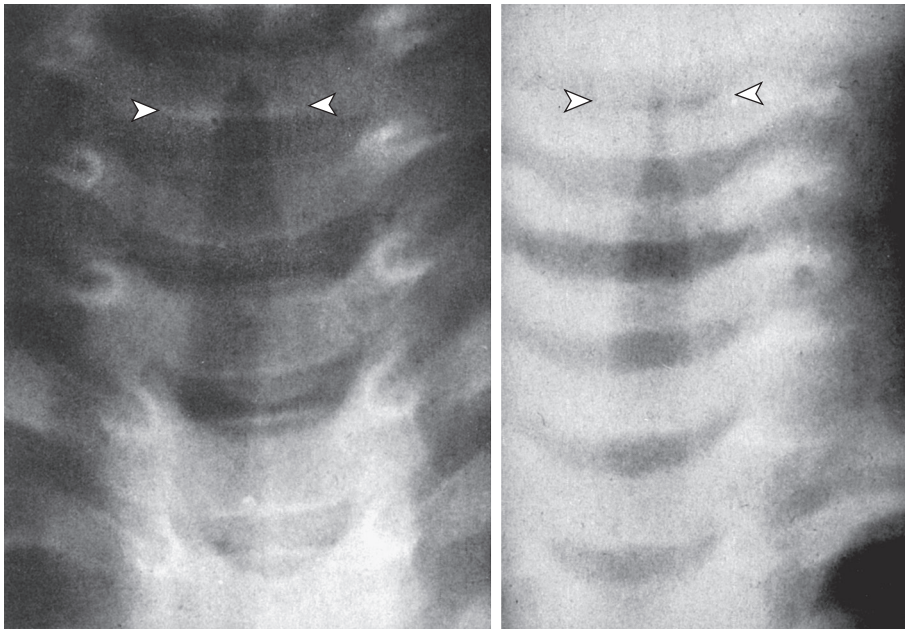

FIG. E3 Laryngotracheobronchitis. Anteroposterior radiograph of the neck. *Left,* A normal tracheal air column (between the *arrows*). *Right,* Trachea narrowed *(arrows)* by laryngotracheobronchitis. (From Fuhrman BP et al: *Pediatric critical care,* Philadelphia, ed 4, 2011, Saunders.)

DISPOSITION

- Croup is usually benign and self-limited, resolving within 3 to 4 days.
- Complications include:
  1. Airway obstruction
  2. Otitis media
  3. Pneumonia
  4. Dehydration

REFERRAL

If intubation is needed (rarely), an emergency consultation with otolaryngology (ENT) and/or anesthesiology is recommended.

PEARLS & CONSIDERATIONS

COMMENTS

- Most patients with croup can be managed at home (e.g., patients without stridor and in no respiratory distress).
- Hospitalization and observation are required for children with moderate to severe croup (e.g., rest stridor, respiratory distress refractory to the previously mentioned acute treatments). A family history of croup is a risk factor for croup and recurrent croup.
- Heliox: Helium-oxygen therapy has shown benefit in acute RSV infections and bronchiolitis, but in general there is little evidence to support its use in croup.

Cryoglobulinemia

BASIC INFORMATION

DEFINITION

Cryoglobulins are serum immunoglobulins that precipitate when cooled and redissolve when heated. A classification of cryoglobulins is described in Table 1 and Fig. 1. Cryoglobulinemia is a clinical syndrome that results from systemic inflammation caused by cryoglobulin-containing immune complexes. Mixed cryoglobulinemia is a vasculitis of small and medium-sized arteries and veins due to the deposition of complexes of antigen, cryoglobulin, and complement in the vessel walls. Classification criteria for cryoglobulinemic vasculitis is summarized in Table 2.

SYNONYMS

Cryoglobulinemic vasculitis
Cryoproteinemia
Mixed cryoglobulinemia
Essential cryoglobulinemia

ICD-10CM CODES

D89.1 Cryoglobulinemia

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Prevalence of mixed cryoglobulinemia is approximately 1:100,000 and accounts for 85% to 90% of cryoglobulinemic vasculitis cases.
- Approximately 19% to 50% of patients with HCV are found to have mixed cryoglobulinemia; only 5% to 10% develop vasculitis.
- Three types: I (monoclonal), II (IgM monoclonal and IgG polyclonal), and III (polyclonal).

PREDOMINANT SEX AND AGE: Female-to-male ratio of 3:1

PREDOMINANT AGE: Mean age reported is 42 to 52 yr.

RISK FACTORS:

- HCV infection
- Connective tissue disorders
- Lymphoproliferative disorders

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- *Meltzer triad* of purpura, arthralgias/myalgia, and weakness is seen in one third of patients.
- Palpable purpura occurs in approximately 90% of patients.
- Other symptoms include dyspnea, cough, numbness, abdominal pain, acrocyanosis, Raynaud phenomenon, ischemic ulcers, hypertension, hepatomegaly, livedo reticularis, and in severe cases, distal necrosis, retiform purpura of lower extremities (Fig.E2), and ulcerations of lower limbs.

ETIOLOGY

- Intravascular deposition of cryoglobulins leading to ischemic insults in territory supplied by vasa nervorum
- Necrotizing vasculitis caused by cryoglobulin precipitation in cooler areas (distal extremities) and kidneys (increased concentration due to ultrafiltration)

TABLE 1 Classification of Cryoglobulins

Type	Composition	Associated Disease
I	Monoclonal IgG, IgA, or IgM	Multiple myeloma (IgG, IgM) Chronic lymphocytic leukemia Waldenstrom macroglobulinemia Idiopathic monoclonal gammopathy Lymphoproliferative disorders
II	Polyclonal IgG and monoclonal IgM (with rheumatoid factor activity)	Hepatitis C, hepatitis B, HIV Neoplasms: Chronic lymphocytic leukemia, diffuse lymphoma, B lymphocytic neoplasia
III	Polyclonal IgG and polyclonal IgM	Infections: Viral (hepatitis B and C, Epstein-Barr virus, cytomegalovirus), bacterial (endocarditis, leprosy, poststreptococcal glomerulonephritis), parasitic (schistosomiasis, toxoplasmosis, malaria) Autoimmune disorders: Systemic lupus erythematosus, rheumatoid arthritis Lymphoproliferative disorders Chronic liver disease

IgG, Immunoglobulin G; *IgA,* immunoglobulin A; *IgM,* immunoglobulin M.
From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, Saunders.

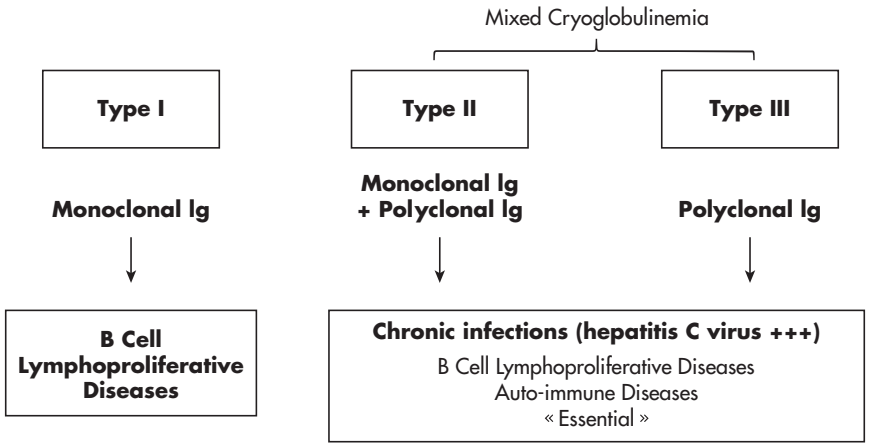

FIG. 1 Cryoglobulin immunotyping and related underlying diseases. *Ig,* Immunoglobulin. (From Cacoub P et al: Cryoglobulinemia vasculitis. *Am J Med* 128[9]:950–955.)

TABLE 2 Classification Criteria for Cryoglobulinemic Vasculitis

Satisfied if at least two of the three items (questionnaire, clinical, laboratory) are positive. The patient must be positive for serum cryoglobulins in at least two determinations at ≥12-wk intervals.

1. Questionnaire item: At least two of the following

- Do you remember one or more episodes of small red spots on your skin, particularly involving the lower limbs?
- Have you ever had red spots on your lower extremities that leave a brownish color after their disappearance?
- Has a doctor ever told you that you have viral hepatitis?

2. Clinical item: At least three of the following four (present or past)

Constitutional symptoms	Fatigue Low-grade fever (37-37.9 °C, >10 days, no cause) Fever (>38 °C, no cause) Fibromyalgia
Articular involvement	Arthralgias Arthritis
Vascular involvement	Purpura Skin ulcers Necrotizing vasculitis Hyperviscosity syndrome Raynaud phenomenon
Neurologic involvement	Peripheral neuropathy Cranial nerve involvement Vasculitic CNS involvement

3. Laboratory item: At least two of the following three (present)

- Reduced serum C4
- Positive serum RF
- Positive serum M component

CNS, Central nervous system; *RF,* rheumatoid factor.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

- Infections: HCV, mycosis fungoides, HBV, HIV, Epstein-Barr virus, cytomegalovirus, *Treponema pallidum,* Mycobacterium leprae, and in post-streptococcal glomerulonephritis
- Lymphoproliferative disorders: Chronic lymphocytic leukemia, Waldenström macroglobulinemia, multiple myeloma
- Connective tissue disorders: Sjögren syndrome, rheumatoid arthritis, systemic lupus erythematosus (SLE), scleroderma, vasculitis
- Renal diseases including proliferative glomerulonephritis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Antiphospholipid syndrome
- SLE
- Churg-Strauss syndrome
- Cirrhosis
- Glomerulonephritis
- Goodpasture syndrome
- Hemolytic uremic syndrome
- Hepatitis
- Lymphoma
- Sarcoidosis
- Waldenström hypergammaglobulinemia

WORKUP

History and physical examination; laboratory tests; imaging tests depending on patients' presentation.

LABORATORY TESTS

- Serum cryoglobulins, rheumatoid factor, serum complement, hepatitis C titer, urinalysis, CBC, ALT, AST, BUN, creatinine.
- Sample collection for cryoglobulins is essential. Sample tubes should be prewarmed and kept at 37 °C through transport and processing.
- Electromyogram/nerve conduction studies may demonstrate axonal changes and distal muscle denervation.
- Sural nerve and skin biopsy.

IMAGING STUDIES

Chest x-ray for pulmonary involvement, CT scan to evaluate for malignancy, and angiography for vasculitis

TREATMENT

- Management of type I cryoglobulinemia is directed at treating the underlying disorder.

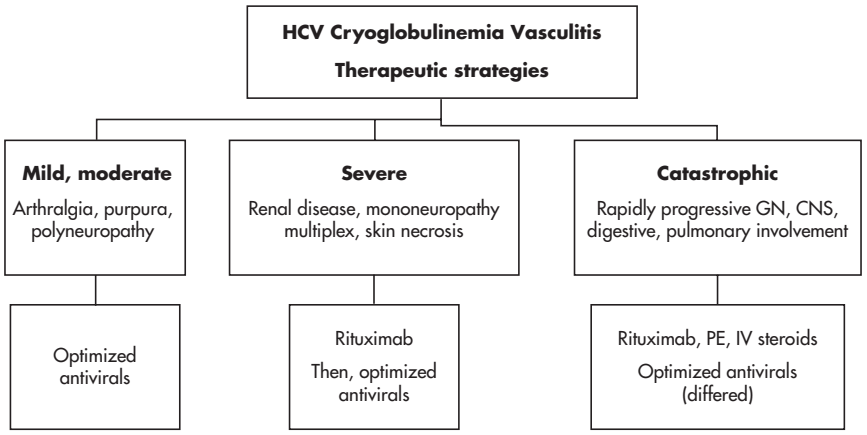

FIG. 3 Treatment of HCV-related mixed cryoglobulinemia vasculitis according to the presentation. *CNS,* Central nervous system; *GN,* glomerulonephritis; *HCV,* hepatitis C virus; *IV,* intravenous; *PE,* pulmonary embolism. (From Cacoub P et al: Cryoglobulinemia vasculitis, *Am J Med* 128[9]:950–955.)

- For noninfectious mixed cryoglobulinemia, treatment is based on disease severity. Low-dose corticosteroids, NSAIDs, and colchicine should be given for mild symptoms. Rituximab, high-dose corticosteroids, cyclophosphamide, and/or plasmapheresis should be given for severe disease.
- In patients with HCV, mild symptoms can be managed by treatment with direct-acting antivirals (DAA). Therapy is aimed at eradicating the HCV infection, suppressing B-cell clonal expansion and cryoglobulin production, and ameliorating symptoms.
- For severe disease in HCV-infected patients, initial immunosuppression with rituximab is warranted, followed by initiation of antiviral therapy.
- Fig. 3 illustrates the treatment of HCV-related mixed cryoglobulinemia vasculitis according to presentation.
- Sustained virologic response due to DAA does not always fully eradicate cryoglobulinemia but can help mitigate its manifestations.

NONPHARMACOLOGIC THERAPY

Avoidance of cold exposure, diabetic food care guidelines

ACUTE GENERAL Rx

NSAIDs in those with general fatigue and arthralgia; see "Treatment" for further management.

DISPOSITION

Overall prognosis is worse with concomitant renal disease. Mean survival rate is ~50% at 10 yr.

REFERRAL

Consider referring to the following:

- Nephrologist if there is renal involvement
- Hematologist in patients with lymphoproliferative disorders
- Gastroenterologist/hepatologist in patients with hepatitis
- Rheumatologist in patients with connective tissue disease cases
- Clinical immunologist in severe cases

PEARLS & CONSIDERATIONS

COMMENTS

Always look for underlying cause of cryoglobulinemia.

PREVENTION

Avoidance of cold exposure, avoidance of late complications.

PATIENT & FAMILY EDUCATION

Inform patients about early signs/symptoms of cryoglobulinemia so that treatment can be rendered before the development of complications.

Cryptococcosis PTG

BASIC INFORMATION

DEFINITION

Cryptococcosis is an infection caused by the encapsulated yeast *Cryptococcus* spp.

SYNONYMS

C. neoformans infection
C. gattii infection
C. albidus infection
C. laurentii infection

ICD-10CM CODES

B45.09	Pulmonary cryptococcosis
B45.1	Cerebral cryptococcosis
B45.2	Cutaneous cryptococcosis
B45.3	Osseous cryptococcosis
B45.7	Disseminated cryptococcosis
B45.9	Cryptococcosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- 0.8 cases per million persons/yr; *C. neoformans* is an important opportunistic infection in patients with deficits in cell-mediated immunity.
- 2 to 7 per 1000 persons living with AIDS/yr.

PEAK INCIDENCE: 20 to 40 yr (parallel to HIV/AIDS epidemic)
PREDOMINANT SEX: Equal sex distribution when adjusted for HIV status
PREDOMINANT AGE: Less than 2 yr of age; 20 to 40 yr of age
NEONATAL INFECTION: Very uncommon

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- More than 90% present with meningitis (generally subacute); almost all have fever and headache
- Meningismus, photophobia, mental status changes are seen in approximately 25%
- Increased intracranial pressure may be present
- Most common infections outside the CNS:
  1. In the lungs (fever, cough, dyspnea, and typically with lobar consolidation)
  2. In the skin (cellulitis, papular eruption)
  3. In the lymph nodes (lymphadenitis)
  4. Potential involvement of virtually any organ (e.g., prostate and bone)

ETIOLOGY

- There are four *Cryptococcus spp.* that cause disease in humans, although most laboratories are not able to differentiate between species. *C. neoformans* (Table E1) is the cause of a majority of global disease burden, primarily in immunocompromised patients. *C. gattii* infections are much less common and occur more often in normal hosts, with recent outbreaks in the Pacific Northwest. *C. albidus* and *C. laurentii* are even rarer causes of disease.
- Infection originates by inhalation into the respiratory tract followed by dissemination to the CNS in most cases, usually without recognizable lung involvement.
- Almost always in the setting of AIDS (most with CD4 counts <100) or other disorders of cellular immune function, such as organ transplantation.
- Neutropenia alone poses a much lower risk of significant cryptococcal infection.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Subacute meningitis (caused by *Listeria monocytogenes,* Mycobacterium tuberculosis, *Histoplasma capsulatum,* viruses)
- Intracranial mass lesion (neoplasms, toxoplasmosis, TB)
- Pulmonary involvement confused with *Pneumocystis jiroveci* pneumonia when diffuse or confused with TB or bacterial pneumonia when focal or involving the pleura
- Skin lesions can take many forms and may be confused with bacterial cellulitis or molluscum contagiosum

WORKUP

- Lumbar puncture to exclude cryptococcal meningitis, with measurement of opening pressure because CSF opening pressure is elevated in 60% to 80% of HIV patients and may require drainage. In cryptococcal meningitis, CSF reveals lymphocytic pleocytosis (although a paucity of WBCs may be found in CSF of HIV patients)
- CT scan of the head when focal lesion or increased intracranial pressure is suspected
- Biopsy of enlarged lymph nodes and skin lesions if feasible

LABORATORY TESTS

- Culture and India ink stain (60% to 80% sensitive in culture-proven cases [Fig. E1]); examination of the CSF in all cases when CNS involvement is suspected
- Blood and serum cryptococcal antigen assay (>90% sensitivity and specificity in immunocompromised patients; lower sensitivity in immunocompetent patients)
- Culture and histologic examination of biopsy material
- HIV antibody testing

IMAGING STUDIES

- CT scan or MRI of the head if focal neurologic involvement or cryptococcoma is suspected
- Chest x-ray examination to exclude pulmonary involvement

TREATMENT

ACUTE GENERAL Rx

- Treatment of cryptococcosis consists of three stages: Induction, consolidation, and maintenance. Induction therapy for CNS disease (meningitis) was historically initiated with IV amphotericin B deoxycholate (0.7 to 1.0 mg/kg/day) with flucytosine 100 mg/kg/day PO in four divided doses; however, there is growing clinical evidence for liposomal amphotericin B (3 to 6 mg/kg/day) plus flucytosine, especially in HIV-infected patients and in those with renal dysfunction. Induction therapy is generally recommended for 2 to 4 wk and until repeat CSF cultures are negative; it is then recommended to transition to consolidation therapy with fluconazole 400 mg PO q24h for 8 wk, followed by ongoing fluconazole 200 mg PO q24h maintenance therapy (up to 2 yr) to reduce relapse rate. Maintenance therapy is indicated in patients with AIDS until these patients have been receiving antifungal therapy for at least 1 yr and they have responded to antiretroviral therapy (CD4 cell count ≥100/microliter for ≥3 mo). In patients without HIV, the duration of maintenance therapy is generally 6 to 12 mo. Lifelong antifungal therapy is needed in organ transplant patients.
- Alternative: IV fluconazole combined with flucytosine for initial therapy in patients unable to tolerate amphotericin B.
- If symptomatic increased intracranial pressure, consider multiple therapeutic lumbar taps or intraventricular shunt.
- Data support increased mortality with early initiation of antiretroviral therapy in the setting of cryptococcal meningitis due to immune reconstitution syndrome; therefore it is generally recommended to wait 2 to 10 wk after starting cryptococcal therapy prior to starting antiretroviral therapy.
- CSF removal with daily lumbar puncture or insertion of a shunt is beneficial in patients with elevated intracranial pressure.

CHRONIC Rx

- Fluconazole (200 to 400 mg PO qd) is highly effective in preventing a relapse in HIV-infected patients; development of resistance may occur. Itraconazole is an alternative agent, along with growing evidence for voriconazole and posaconazole use.

DISPOSITION

Without maintenance therapy, relapse rate is >50% among AIDS patients.

REFERRAL

- For consultation with infectious diseases specialist in all cases
- For neurologic consultation if level of consciousness is depressed or focal lesion is present

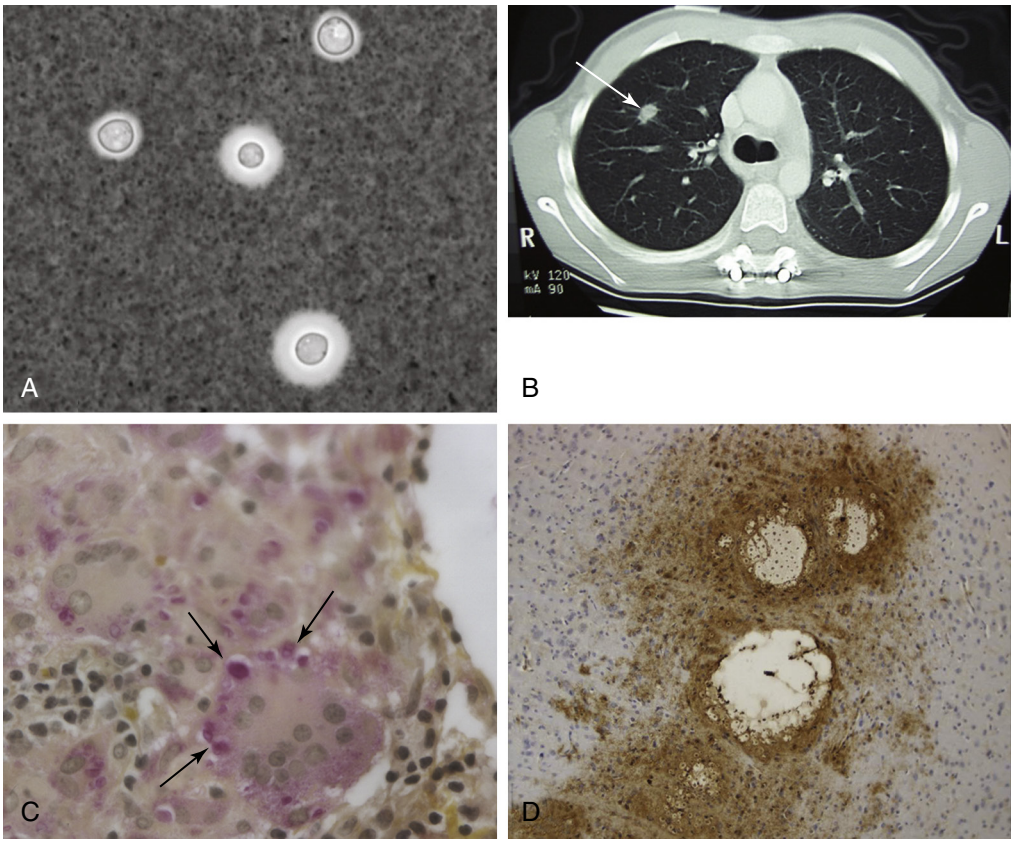

FIG. E1 A, India ink staining of cerebrospinal fluid demonstrates *Cryptococcus neoformans* and capsule, which excludes the stain and results in a halo around the organism. **B,** Computed tomography scan of a child with rhabdomyosarcoma reveals nodule *(white arrow)* secondary to *C. neoformans*. **C,** Mucicarmine staining of a lung from a rat with experimentally induced pulmonary cryptococcosis shows granulomas containing *C. neoformans (black arrows).* **D,** Immunostaining for cryptococcal polysaccharide reveals extensive shedding of polysaccharide within the brain parenchyma and around cryptococcomas of a rat with experimentally induced cryptococcal meningoencephalitis. (From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.)

BASIC INFORMATION

DEFINITION

Cryptogenic organizing pneumonia (COP) is a type of idiopathic interstitial pneumonia, which has a histologic pattern of organizing pneumonia combined with characteristic clinical and radiographic features. The histologic pattern of organizing pneumonia consists of intraluminal organizing fibrosis in distal airways with intraalveolar buds of granulation tissue composed of connective tissue, fibroblasts, and myofibroblasts. Foci of organizing pneumonia tend to have a patchy distribution and uniform appearance with relative preservation of underlying lung architecture. Cryptogenic organizing pneumonia has no known underlying cause. Secondary causes associated with a histologic pattern of organizing pneumonia must be clinically excluded.

SYNONYMS

Bronchiolitis obliterans organizing pneumonia (BOOP)
COP

ICD-10CM CODE
J84.116 Cryptogenic organizing pneumonia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Estimated incidence is six to seven cases per 100,000 per yr
PEAK INCIDENCE: Typically, age of onset is 50 to 60 yr old
PREVALENCE: Unknown
PREDOMINANT SEX AND AGE: No sex predominance
GENETICS: Unknown
RISK FACTORS: Unknown

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The clinical presentation ranges from an acute onset of flulike symptoms to a subacute illness with cough and dyspnea. Common presenting symptoms are fevers, dyspnea, nonproductive cough, malaise, and weight loss. Symptoms are typically present for less than 3 months in the majority of cases. A lack of response to antibiotics for the treatment of community-acquired pneumonia may raise suspicion for cryptogenic organizing pneumonia. Lung examination may be remarkable for inspiratory crackles or may be normal.

ETIOLOGY

The etiology of cryptogenic organizing pneumonia is unknown. The pathogenesis may begin with alveolar epithelial injury of an unknown cause.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Community-acquired pneumonia, chronic eosinophilic pneumonia, and hypersensitivity pneumonitis can have similar clinical presentations and radiographic features. The differential diagnosis also includes other types of idiopathic interstitial pneumonias and secondary causes of organizing pneumonia, which need to be excluded (Table E1).

WORKUP

Chest imaging is commonly performed (see "Imaging Studies"). Pulmonary function testing may show a mild to moderate restrictive pattern with a reduced diffusion capacity. Bronchoscopy with bronchoalveolar lavage (BAL) is performed to evaluate for other disease processes, such as active infection, eosinophilic pneumonia, hypersensitivity pneumonitis, and malignancy. Transbronchial biopsies may be unreliable for detecting organizing pneumonia due to the patchy distribution of the disease. Additionally, when foci of organizing pneumonia are detected (Fig. E1), the relatively small tissue specimens may not be sufficient to exclude other coexisting histopathologic processes. A surgical lung biopsy may be needed to make a definitive diagnosis, especially if clinical and radiographic features are not typical. After a histologic diagnosis of organizing pneumonia is made, additional evaluation for secondary causes is necessary. This may include serologic testing for connective tissue diseases and human immunodeficiency virus, in addition to infectious and hematologic evaluation (Table E1).

LABORATORY TESTS

Leukocytosis without peripheral eosinophilia and elevated inflammatory markers, including elevated erythrocyte sedimentation rate and C-reactive protein, are frequently present. BAL cell counts are remarkable for a mixed pattern, typically with increased lymphocytes (20% to 40%), neutrophils (approximately 10%), and eosinophils (approximately 5%). CD4/CD8 ratio is also decreased in the majority of cases. However, these laboratory tests are all nonspecific.

TABLE E1 Secondary Causes of Organizing Pneumonia

Drug toxicity
Connective tissue disease
Solid and hematologic malignancies
Infection
Radiation injury
Immunodeficiency syndromes including post-organ transplantation

IMAGING STUDIES

Chest radiograph (Fig. E2) and chest computed tomography (CT) scan will typically show unilateral or bilateral peripheral airspace consolidations that may be migratory. On chest CT scan, consolidations are often subpleural or peribronchial in location. Additionally, a perilobular pattern (airspace consolidation at the periphery of a secondary pulmonary lobule) can be present in over half of cases. Ground-glass opacities, nodular or mass-like opacities, and small ill-defined nodules are common (Fig. E3). The reverse halo sign (central ground-glass opacity surrounded by airspace consolidation) is infrequently seen.

TREATMENT

ACUTE GENERAL Rx

For patients with persistent or progressive symptoms, prednisone is initiated at a dose of 0.75 to 1 mg/kg PO daily. Most cases have a rapid improvement with initiation of prednisone.

CHRONIC Rx

Prednisone is weaned over months. Relapse is common but rarely associated with poor outcomes. Prolonged prednisone therapy can be considered for relapsing cases after weighing risks and benefits. Other immunosuppressors, such as cyclophosphamide or azathioprine, can be considered as adjunctive or steroid-sparing therapies. Up to 75% of treated patients continue to have residual CT scan abnormalities.

PEARLS & CONSIDERATIONS

- Chest imaging with peripheral airspace consolidations combined with a clinical presentation of an acute, flulike illness or subacute dyspnea and cough that does not respond to antibiotics should raise suspicion for cryptogenic organizing pneumonia.

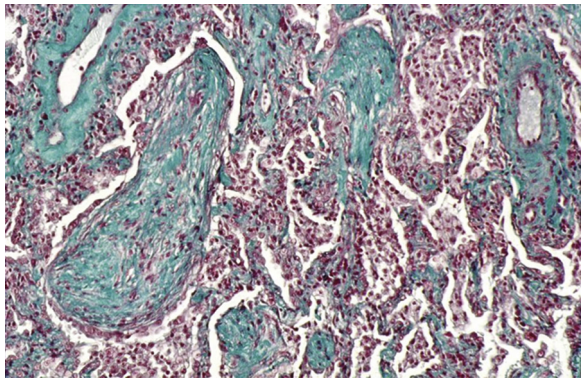

FIG. E1 Photomicrograph indicates organizing pneumonia. Immature connective tissue and proliferating fibroblasts appearing light blue (pentachrome stain) are present in alveolar ducts and alveolar spaces, and there is an interstitial infiltrate consisting of mononuclear cells. (Original magnification ×40.) (From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, Saunders.)

FIG. E2 Chest radiograph demonstrating patchy alveolar opacities in a patient with cryptogenic organizing pneumonia. Enlarged cardiac silhouette is due to an unrelated cardiomyopathy. (From Weinberger SE: *Principles of Pulmonary Medicine,* ed 7, Philadelphia, 2019, Elsevier.)

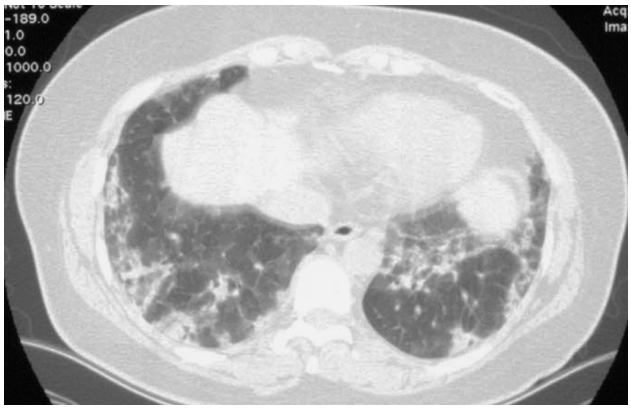

FIG. E3 High-resolution computed tomography image from a patient with cryptogenic organizing pneumonia shows patchy areas of consolidation and diffuse ground-glass opacities (gray-appearing areas). (From Mason RJ et al: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, Saunders.)

- Cryptogenic organizing pneumonia has no known underlying cause. Secondary causes associated with a histologic pattern of organizing pneumonia must be clinically excluded.
- When cryptogenic organizing pneumonia is suspected, bronchoscopy with bronchoalveolar lavage can evaluate for disease mimics, including infection, eosinophilic pneumonia, hypersensitivity pneumonitis, and malignancy. However, tissue biopsies are needed to make a definitive diagnosis, which may require a surgical lung biopsy.

BASIC INFORMATION

DEFINITION

Cryptorchidism is the incomplete or improper descent of the testis (testes) into the scrotum during fetal development. Testes that can be manually manipulated into the scrotum and that remain there without traction until cremasteric reflexes are induced are called *retractile.* Testes previously located but no longer palpable in the scrotum are called *ascended testes.*

SYNONYM

Undescended testis

ICD-10CM CODES

Q53.9	Undescended testicle, unspecified
Q53.10	Unspecified undescended testicle, unilateral
Q53.20	Undescended testicle, unspecified, bilateral

EPIDEMIOLOGY & DEMOGRAPHICS

- Cryptorchidism is the most common genitourinary disorder of male children.
- Occurs in approximately 30% of premature and 5% of term male infants. In 10%, it can be bilateral.
- Spontaneous descent occurs in 35% to 43% of newborn boys with congenital cryptorchidism, usually before 3 mo of age.
- Increased rates with premature birth, low birth weight, twins, cerebral palsy, and family history of cryptorchidism.
- With retractile testes, there is a reported 2% to 45% risk of subsequent ascent leading to an undescended testis, with histopathology in these testes comparable to congenital undescended testis.
- Prevalence of acquired cryptorchidism is 1% to 7%; peaks around 8 yr of age.

CLINICAL PRESENTATION

- Typically asymptomatic and is noted incidentally on screening examination. Undescended testes are at risk for testicular torsion and inguinal hernia.
- The testis may be nonpalpable or palpable in a location along the path of normal descent, or less commonly ectopic and located in the perineum, femoral canal, superficial inguinal pouch, suprapubic area, or contralateral hemiscrotum. Fig. E1 illustrates various positions of the ectopic testis. The majority are located in the inguinal canal.
- Associated with infertility and a threefold increased risk of testicular cancer. Risk of infertility is the greatest for a child with bilateral intraabdominal testes and longer duration of cryptorchidism.

ETIOLOGY

Normal testicular descent is a complex interplay among mechanical (gubernaculums, vas deferens and testicular vessel length, cremasteric muscles, and abdominal pressure), hormonal (gonadotropin, testosterone, dihydrotestosterone, and müllerian inhibiting substance), and neural (ilioinguinal and genitofemoral nerves) factors.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Retractile testis
- Ascended testis
- Atrophic testis
- Vanished testis

WORKUP

- Physical examination:
  1. Examine patient in supine, sitting, and standing positions in a warm room with warm hands, and with adequate cremasteric relaxation to differentiate true cryptorchidism from retractile testes.
  2. Often associated with an indirect inguinal hernia as the tunica vaginalis fails to close above the testis.
  3. An enlarged contralateral testis (16.1 mm or greater in length for patients 6 to 18 mo old; 19 to 20 mm for those 11 to 30 mo old) in the presence of a nonpalpable undescended testis is suggestive of but not definitive for testicular atrophy/absence.

If there are bilateral nonpalpable undescended testes, first rule out congenital adrenal hyperplasia (CAH). If no CAH, then rule out disorders of sexual development (DSD). Müllerian inhibiting substance (MIS or antimüllerian hormone) should be measured and consider additional hormonal testing to evaluate for anorchia (inhibin B, FSH, LH, and testosterone) (evidence grade C).

IMAGING STUDIES

Scrotal/inguinal ultrasound (Fig. E2) and other imaging is not routinely needed because such studies rarely assist in decision making (evidence grade B).

TREATMENT

- Repeat examination at 3 mo of age because many testes will descend spontaneously. Spontaneous descent is rare after 3 mo of age.
- Treatment is primarily surgical and rarely hormonal. Fig. E3 illustrates an algorithm for the management of the undescended testis.
- Referral to an appropriate specialist if spontaneous descent does not occur by 6 mo of age. Earlier orchiopexy may improve testicular function and decrease the risk of testicular cancer. Orchiopexy allows testicular self-examination and detection of testicular cancer if it occurs (evidence grade B).

HORMONAL Rx

- Hormonal therapy (hCG) is not recommended in the American Urological Association Guidelines for the treatment of cryptorchidism.

SURGICAL Rx

- For the palpable undescended testis, orchiopexy (Fig. E4), the surgical placement of an undescended testis into the scrotum, is the standard approach, performed between 6 mo and 1 yr of age in a healthy child. This may be performed through a combined inguinal and scrotal incision or a single scrotal incision, depending on the location of the testis and surgeon preference.
- With a nonpalpable undescended testis, laparoscopy/abdominal exploration is recommended
  1. to identify the presence or absence of a testis,
  2. to identify the location of the testis if present, and
  3. to determine the length of the testicular vessels (evidence grade B) and is the best method of surgical intervention (primary orchiopexy, Fowler-Stephen orchiopexy; one- or two-stage).
- Some surgeons prefer an initial inguinal approach and, if the testis is not identified, then proceed with transinguinal laparoscopy.

DISPOSITION

- Earlier orchiopexy may decrease the risk of malignancy and infertility.
- Lifelong testicular examinations after puberty.

REFERRAL

Early referral (ideally by 6 mo of age) to a pediatric urologist or pediatric surgeon

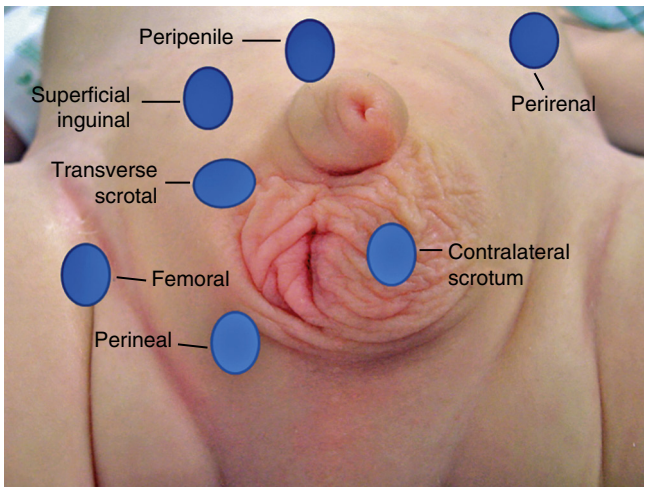

FIG. E1 Positions of the ectopic testis. The ectopic testis can be identified in various positions, as shown. The most common location is the superficial inguinal pouch. (From Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.)

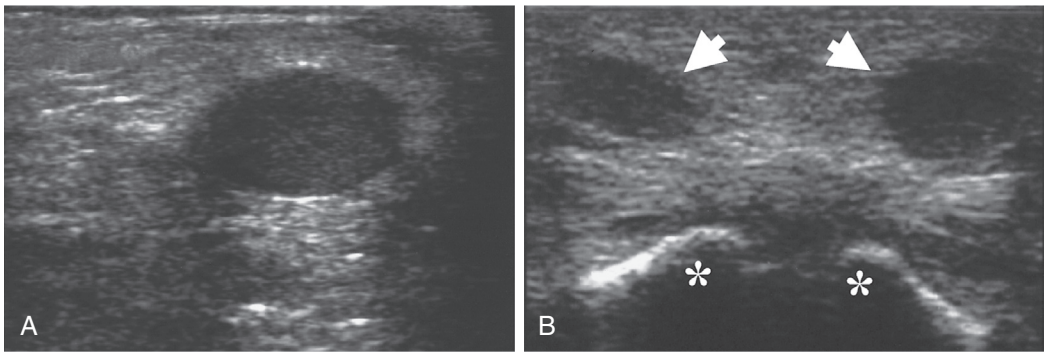

FIG. E2 A, Ultrasound (US) of an undescended infantile testis. The testis lies within the inguinal canal surrounded by suprapubic fat. **B,** Transverse US view of bilateral undescended testes. The testes *(arrows)* are demonstrated at the level of the superior pubic rami *(asterisks).* (From Grant LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

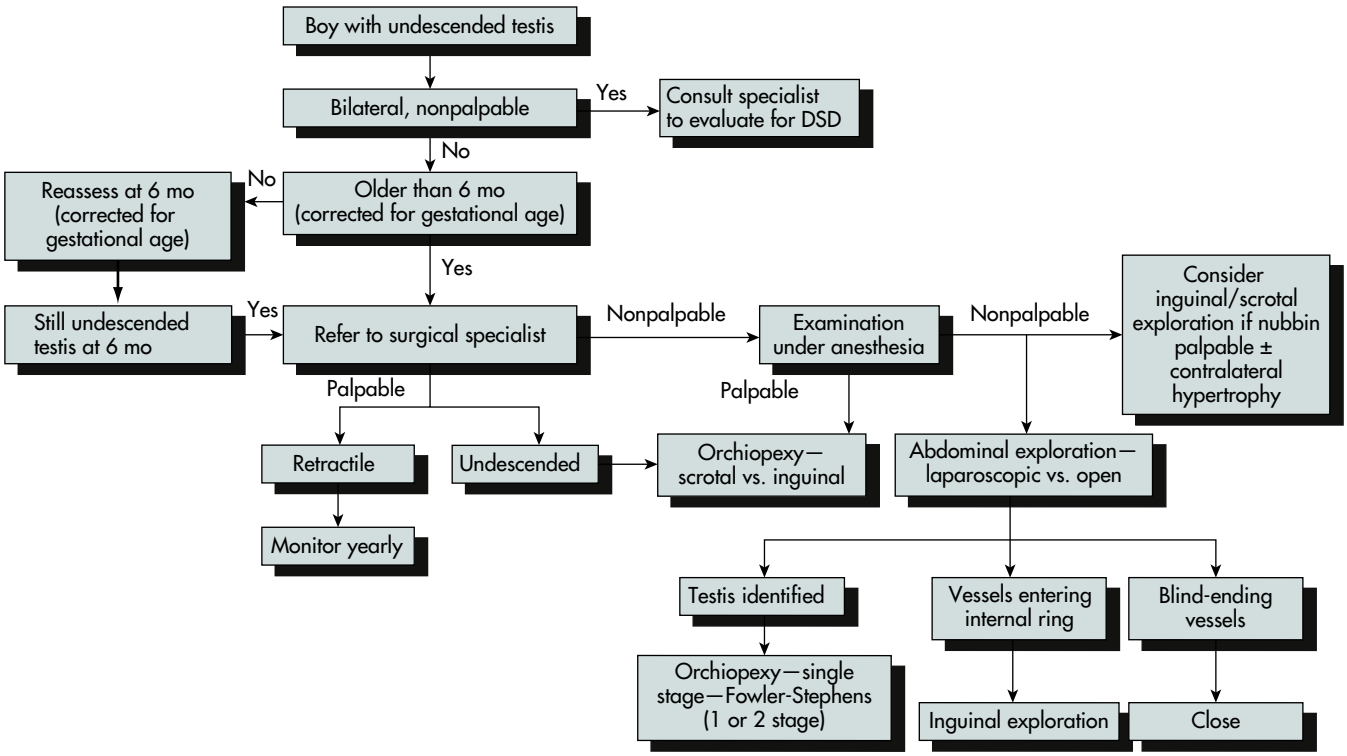

FIG. E3 Algorithm for the management of the undescended testis. The American Urological Association guideline algorithm for the diagnosis and treatment of palpable and nonpalpable testes in patients confirmed to have undescended testis by an experienced examiner. *DSD,* Disorder of sexual differentiation. (From Kolon TF et al: Evaluation and treatment of cryptorchidism: AUA guideline, 2014. Wein AJ et al: *Campbell-Walsh urology*, ed 11, Philadelphia, 2016, Elsevier.)

PEARLS & CONSIDERATIONS

Regular testicular examinations should be performed in infants and children, particularly those with retractile testes, because ascent of scrotal testis can occur.

BASIC INFORMATION

DEFINITION

The intracellular protozoan parasite *Cryptosporidium parvum* is associated with gastrointestinal disease and diarrhea, especially in patients with AIDS or other immunocompromised hosts. It is also associated with sporadic infections and waterborne outbreaks in immunocompetent hosts. Cryptosporidiosis is a notifiable disease in the U.S.

Other species, including *C. hominis, C. felis, C. muris,* and *C. meleagridis,* are now described to be pathogens as well.

SYNONYM

Cryptosporidiosis

ICD-10CM CODE
A07.2 Cryptosporidiosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Approximately 2% in industrial countries, 5% to 10% in developing countries.
- Immunocompromised patients, especially those with HIV/AIDS, are particularly susceptible to infection. 10% to 20% of HIV patients in the United States may excrete cyst.
- Cryptosporidiosis is a leading cause of all waterborne outbreaks in the U.S. An estimated 748,000 cryptosporidiosis cases occur annually, although fewer than 2% are reported. In 2011, more than 9000 cases of cryptosporidiosis were reported in the country. The highest overall reporting rates were observed in the Midwest.[1]

PREVALENCE: Worldwide, especially third-world countries; associated with poor hygiene as a waterborne pathogen.

PREDOMINANT SEX: Male = female

TRANSMISSION:

- Person-to-person (day care, family members)
- Animal-to-person (pets, farm animals). Fig. E1 describes the life cycle of *Cryptosporidium*
- Environmental (water-associated outbreaks, including travel associated with swimming in or drinking contaminated water or eating contaminated food)
- May be significant pathogen causing diarrhea in patients with AIDS

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Spectrum of illness ranging from asymptomatic to severe enteritis (Table E1). Typical cases in immunocompetent hosts result in self-limited diarrhea, whereas immunocompromised hosts are characterized by profuse, watery, nonbloody diarrhea that may lead to dehydration and weight loss
- Usually limited to the gastrointestinal tract; however, in individuals with AIDS, the disease may be fulminant and life-threatening (CD4 counts <50)
- Diarrhea, severe abdominal pain (2 to 28 days)
- Impaired digestion, dehydration
- Fever, malaise, fatigue, nausea, vomiting
- Pneumonia if aspirated

ETIOLOGY

C. hominis, C. parvum, C. felis, C. muris, C. meleagridis

DIAGNOSIS

Clinical presentation of acute gastrointestinal illness, especially associated with HIV/AIDS or with travel and waterborne outbreaks.

DIFFERENTIAL DIAGNOSIS

- *Campylobacter*
- *Clostridium difficile*
- *Entamoeba histolytica*
- *Giardia lamblia*
- *Salmonella*
- *Shigella*
- Microsporidia
- Cytomegalovirus
- *Mycobacterium avium*
- Disease may cause cholecystitis, reactive arthritis, hepatitis, urethritis, pancreatitis, or pneumonia in immunocompromised or HIV-infected patients.

WORKUP

(Table E2)

- Stool evaluation looking for characteristic oocyst by modified acid-fast stain (Fig. E2)
- Direct immunofluorescence using monoclonal antibodies is the gold standard for stool exams
- Rapid antigen detection
- PCR
- HIV antibody testing

TREATMENT

- Handwashing and appropriate decontamination of drinking and recreational water sources.
- May be self-limited in normal host, lasting days to weeks. Antidiarrheal agents Pepto-Bismol, Kaopectate, or loperamide may give symptomatic relief.
- Pharmacologic treatment with antibiotics has been largely unsatisfactory in patients with AIDS. Antiviral therapy is the treatment of choice to restore the immune system. Consider prolonged therapy while awaiting CD4 count recovery and combination therapy in those who fail initial course.
- Oocyst excretion reduction has been shown with nitazoxanide 500 mg PO bid for 3 days in immunocompetent patients. If treatment fails, consider paromomycin, metronidazole, azithromycin, or trimethoprim/sulfamethoxazole. However, these medications have not been approved for treatment of *Cryptosporidium.*
- Nitazoxanide elixir has been approved for the treatment of cryptosporidiosis in children ages 1 to 11 yr.
- Biliary cryptosporidiosis can be treated with antiretroviral therapy in the HIV setting.

DISPOSITION

- A self-limited disease in immunocompetent patients with complete recovery over 2 to 3 weeks.
- In patients with AIDS, chronic infection often clears with initiation and maintenance of antiretroviral therapy.
- Chronic arthralgia, headache, malaise, and weakness may persist after infection, even in immunologically normal people.
- If severe and prolonged disease (>30 days), testing for HIV and other immunocompromised states is appropriate, along with a referral to an infectious diseases specialist or gastroenterologist.

REFERRAL

- To an infectious diseases specialist if symptoms persist and/or HIV infection is found
- To a gastroenterologist if chronic malabsorption, or biliary or pancreatic complications occur

PEARLS & CONSIDERATIONS

- Chronic cryptosporidiosis (>30 days of diarrhea from *Cryptosporidium* spp. infection) in a patient with HIV is an AIDS-qualifying opportunistic infection.
- *Cryptosporidium hominis* has a limited host range (humans), whereas *Cryptosporidium parvum* has a wide host range including humans, horses, cattle, other domesticated animals, and wild animals; both species present similarly in humans.

[1] Cryptosporidiosis surveillance, United States, 2011-2012. MMWR 64 3 (2015).

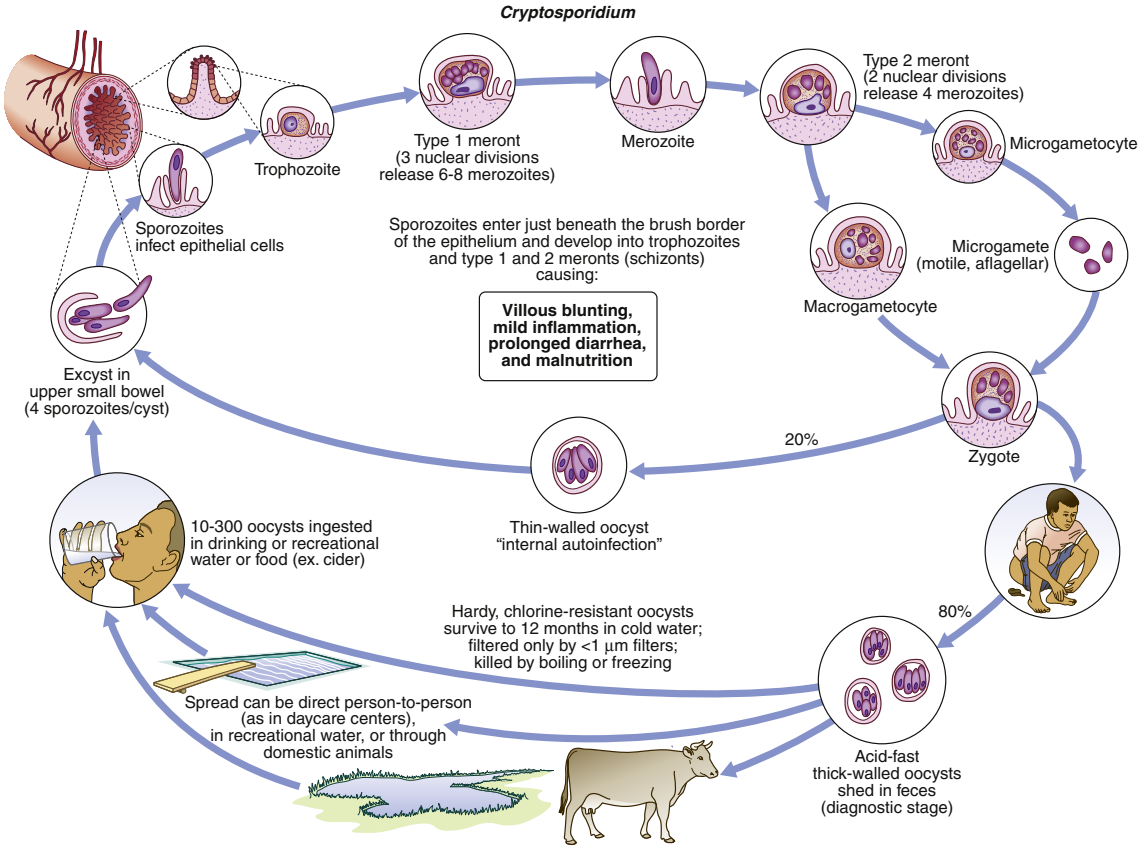

FIG. E1 Life cycle of *Cryptosporidium.* Oocysts are excreted in the feces. After ingestion, the sporozoites are released from the oocysts and attach to and invade intestinal epithelial cells. The cells engulf the parasites into a parasitophorous vacuole, where they enlarge to form the trophozoites; undergo asexual multiplication, forming type 1 meronts; and release the motile merozoites. The type II meronts differentiate into microgamonts and macrogamonts. The microgametes fertilize the macrogametes to form the zygote. The zygotes develop into the oocysts. Two different types of oocysts are produced: the thick-walled, which is commonly excreted from the host, and the thin-walled, which is primarily involved in autoinfection. Oocysts are infective upon excretion, thus permitting direct and immediate fecal-oral transmission. (From Lima AM et al: Cryptosporidiosis. In Guerrant RL et al [eds]: *Tropical infectious diseases,* ed 3, Philadelphia, 2011, Saunders; Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2005, Saunders.)

TABLE E1 Clinical Manifestation of Cryptosporidiosis

Host	Clinical Manifestations	Comments
Normal host	Acute watery diarrhea	Relapses common Persistent diarrhea common
Children in developing countries	Acute watery diarrhea	Diarrhea more severe in children with malnutrition
	Persistent diarrhea	Persistent diarrhea affecting nutritional status, growth, and intellectual function
Immunocompromised host	Acute watery diarrhea	Transient, self-limited, similar to disease in normal host
	Relapsing diarrhea	Very common
	Persistent or chronic diarrhea	Usually found in patients with low CD4 count or malnutrition
	Cholera-like illness	Voluminous watery diarrhea, only with very low CD4 count
	Extraintestinal involvement	Respiratory tract, biliary tract, and pancreas

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

TABLE E2 Diagnosis of *Cryptosporidium* Infection

Test Type	Method	Comments
Microscopic examination of stools	Modified acid-fast stain of stools	Inexpensive and widely available diagnostic test
	Fluorescent stains (auramine O, auramine-rhodamine)	Faster than other acid-fast stains and may improve sensitivity
	Immunofluorescent assays	More sensitive than acid-fast staining but also more expensive
Antigen-detection assays	Enzyme immunoassay and immunochromatographic tests: Direct and indirect immunofluorescence assay	Good sensitivity (66%-100%) and excellent specificity (93%-100%), but occasional lots associated with false-positive test results
Molecular methods	Polymerase chain reaction	Increased sensitivity in contrast to microscopic or antigen-detection studies

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

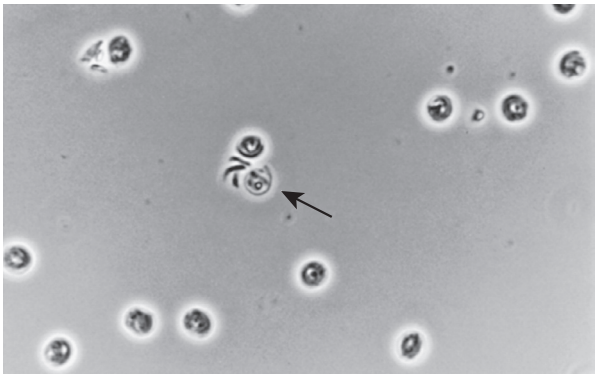

FIG. E2 Human stool-derived *Cryptosporidium* oocysts. Excysting oocyst *(arrow)* is releasing three of its four sporozoites. (Phase-control microscopy ×630.) (From Gorbach SL: *Infectious diseases,* ed 2, Philadelphia, 1998, Saunders.)

BASIC INFORMATION

DEFINITION

Cubital tunnel syndrome is a compressive or entrapment neuropathy of the ulnar nerve as it traverses the cubital tunnel at the elbow, causing weakness, pain, and sensory disturbances in the hand (Fig. E1). If left untreated, cubital tunnel syndrome may lead to permanent disability in the affected hand. The cubital tunnel lies between the medial epicondyle of the humerus and the olecranon process of the ulna. The roof of the cubital tunnel is formed by a fascial band (Osborne ligament) between the two heads of the flexor carpi ulnaris. The floor consists of the medial collateral ligament and olecranon.

ICD-10CM CODE

G56.20 Lesion of ulnar nerve, unspecified upper limb

EPIDEMIOLOGY & DEMOGRAPHICS

Cubital tunnel syndrome is the second most commonly diagnosed compressive neuropathy of the upper extremity after carpal tunnel syndrome, and it is the most common ulnar nerve neuropathy. Its incidence is 24.7 cases per 100,000 persons per yr. Men are more frequently affected than women at a 2:1 ratio.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients often complain of numbness and paresthesia along the distribution of the ulnar nerve (little finger and medial half of ring finger); pain rarely occurs in the hand.
- Pain is typically localized to the cubital area, but symptoms can affect the medial epicondyle and forearm.
- Complaints of hand grip problems (weakness) or hand clumsiness are common.
- If the condition is left untreated, patients may present with atrophy of the first dorsal interosseus or hypothenar eminence atrophy, or with an ulnar claw hand deformity.

The following provocative maneuvers and physical signs are helpful in identifying ulnar neuropathy when interpreted in the proper clinical context.

- Positive Tinel sign (at elbow over the ulnar groove—highest negative predictive value
- Positive elbow flexion test (flexion of elbow with wrist extended for 30 seconds reproduces symptoms)
- Pressure provocation test (direct pressure over cubital tunnel for 60 seconds elicits symptoms)
- "Scratch collapse" test (positive if temporary loss of external rotation resistance occurs after examiner scratches over the compressed ulnar nerve)
- Signs of old trauma or elbow instability (valgus stress)
- Ulnar nerve may sublux over medial epicondyle with elbow motion
- Weakness or atrophy of intrinsic musculature of hand in longstanding cases
- Altered 2-point discrimination
- Duchenne sign, also known as intrinsic minus or claw hand; caused by paralysis of lumbrical and interosseous muscles (clawing is usually worse in ring and small fingers)
- Masse sign—hand appears flattened due to hypothenar muscle paralysis
- Wartenberg sign—caused by weakness of interossei: Weak adduction of small finger
- Froment sign—compensation by thumb flexor (flexor pollicis longus, median-nerve innervated) for diminished thumb pinch strength (paralysis of adductor pollicis, which is innervated by ulnar nerve)

ETIOLOGY

Cubital tunnel syndrome can be idiopathic or caused by some predisposing factors:

- Blunt trauma, fractures
- Metabolic derangements (e.g., diabetes)
- Compression during general anesthesia
- Hemophilia (leading to hematomas)
- Cigarette smoking
- Chronic pressure over ulnar groove from occupational stress, unusual elbow positioning
- Cubitus valgus deformity secondary to old trauma (childhood supracondylar fracture)
- Subluxation of ulnar nerve
- Repeated stretching during throwing motion
- Elbow synovitis, osteophytes
- Local muscular hypertrophy
- Increased cubital tunnel pressure, particularly in elbow flexion
- Anconeus epitrochlearis (an accessory anconeus muscle at the medial elbow)

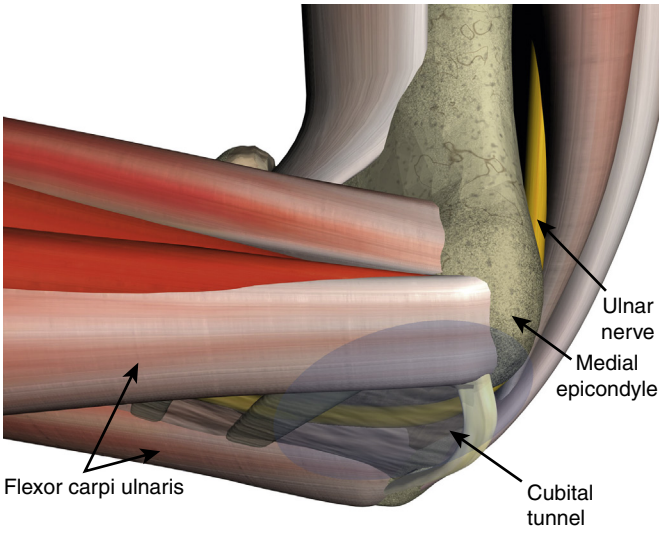

FIG. E1 Cubital tunnel. (Original art by Dr. DaSilva)

DIAGNOSIS

In most patients, a thorough history and physical examination are sufficient to make the diagnosis. Laboratory, electrophysiologic, and imaging studies can help support the diagnosis.

DIFFERENTIAL DIAGNOSIS

- Medial epicondylitis
- Carpal tunnel syndrome
- Cervical disc disease (radiculopathy)
- Thoracic outlet syndrome
- Ulnar nerve compression at wrist (Guyon canal)
- Guillain-Barré syndrome
- Amyotrophic lateral sclerosis
- Pancoast tumor

WORKUP

LABORATORY STUDIES: Specific laboratory studies can help rule out alternate diagnoses and confirm predisposing conditions:

- Complete blood count
- Folate and vitamin B_{12} levels
- Urinalysis
- Thyroid function tests
- Renal function tests
- Fasting blood glucose
- Hemoglobin A1C
- Inflammatory markers (erythrocyte sedimentation rate, C-reactive protein [ESR, CRP]), antinuclear antibodies (ANA)
- HIV, hepatitis, and Lyme serology

IMAGING STUDIES

- Radiographs of the elbow should be obtained in all patients.
- Radiographs of the neck and chest may be done to rule out suspected conditions such as cervical disc disease or Pancoast tumor.
- High-resolution ultrasound can be a valuable adjunct to the diagnosis and may identify the structural etiology of nerve compression. Because of the real-time nature of ultrasound evaluation, dynamic testing can be performed and ulnar nerve subluxation may be observed during elbow flexion and extension motions.
- Trials of diagnostic ultrasound have shown a strong correlation between greater ulnar nerve cross-sectional area at the elbow and presence of cubital tunnel syndrome diagnosed by electrodiagnostic criteria.

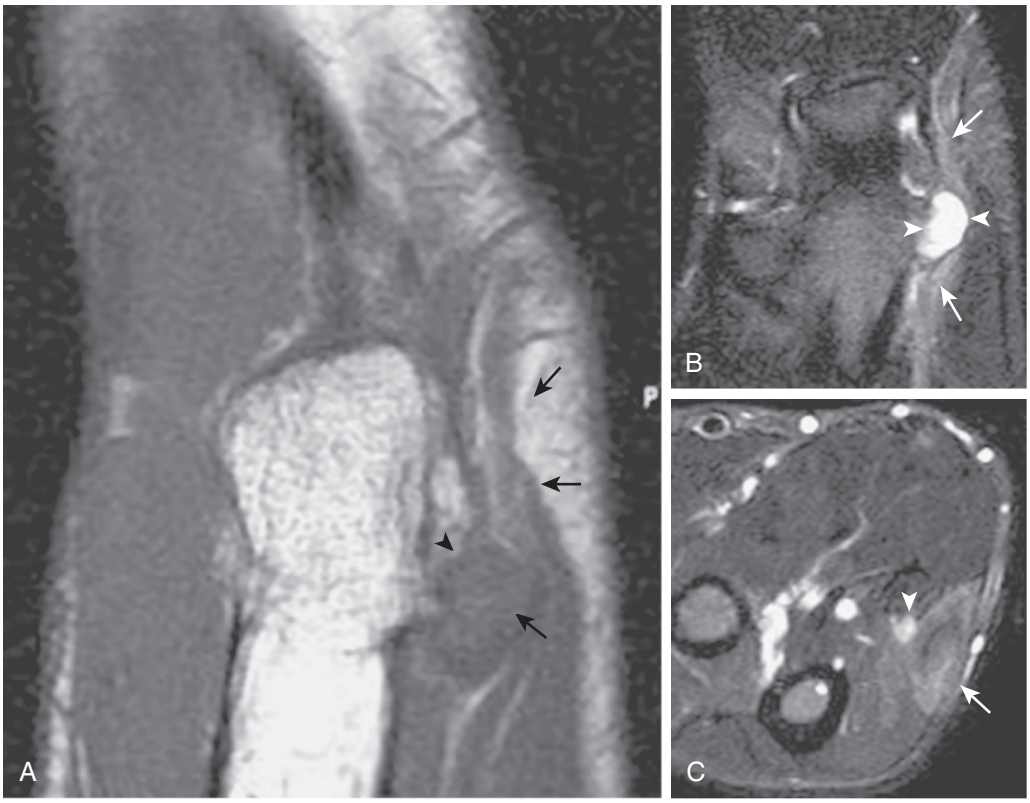

FIG. E2 Cubital tunnel syndrome. Coronal T1-weighted **(A)** and coronal short tau inversion recovery **(B)**. Magnetic resonance (MR) images show a ganglion cyst *(arrowheads)* within the cubital tunnel, producing compression and displacement of the ulnar nerve *(arrows)*. **(C),** Axial T2-weighted MR image distal to the elbow joint demonstrates an enlarged and hyperintense ulnar nerve *(arrowhead)* and early denervation with edema of the flexor carpi ulnaris muscle *(arrow)*. (From Pope TL et al: *Musculoskeletal imaging*, ed 2, Philadelphia, 2014, Saunders.)

- MRI (Fig. E2) may be useful in patients in whom history, physical examination, and electrophysiologic studies fail to support the diagnosis.

ELECTRODIAGNOSTIC STUDIES

Nerve conduction tests and electromyography are useful to confirm the clinical diagnosis and can help localize the site of compression.

Rx TREATMENT

- Nonsurgical options:
  1. Activity modification; avoiding prolonged/repetitive flexion of elbow
  2. Anterior shell splint limiting flexion to 45 degrees to be worn at night
  3. Elbow pads to relieve pressure; physical and occupational therapy
  4. Pain control and alleviation of sensory symptoms using NSAIDs, tricyclic antidepressants, or anticonvulsants
- If nonsurgical options fail to control symptoms or if the patient has significant muscle weakness or atrophy, then surgical options are available:
  1. Endoscopic cubital tunnel release
  2. Ulnar nerve decompression in situ
  3. Anterior transposition of the ulnar nerve
- Common causes for failed surgical management include:
  1. Technical factors such as incomplete decompression or creation of a new area of compression
  2. Incorrect diagnosis or a concomitant double crush lesion such as thoracic outlet syndrome, cervical radiculopathy, or Guyon canal syndrome
  3. Biologic causes such as severe preoperative nerve damage or perineural scarring

DISPOSITION

- There is a tendency toward spontaneous recovery with mild or moderate or intermittent symptoms if provocative causes are avoided.
- If muscle atrophy has developed, recovery of strength may be incomplete despite treatment, suggesting the importance of prompt diagnosis and appropriate treatment.

REFERRAL

Surgical referral is needed in cases of failed nonsurgical management. Patients with constant symptoms or muscle atrophy usually require surgical treatment.

PEARLS & CONSIDERATIONS

- A thorough history and physical examination and knowledge of the sensory and motor innervation of the upper extremity are usually sufficient to make the diagnosis.
- Patients with mild, intermittent symptoms can have spontaneous recovery if provocative causes are avoided.
- Nonsurgical management should be attempted, but if symptoms are persistent or if significant hand muscle weakness or atrophy is present, then surgery may be indicated.
- In patients with advanced findings, electromyogram/nerve conduction studies can help predict nerve and muscle function recovery after surgery.
- Surgical decompression has been shown to be successful in most cases. More recently, endoscopic decompression techniques have been described.

Cushing Disease and Syndrome ALG PTG

BASIC INFORMATION

DEFINITION

- Cushing syndrome is the occurrence of clinical abnormalities associated with glucocorticoid excess as a result of exaggerated adrenal cortisol production or long-term glucocorticoid therapy.
- Cushing disease is Cushing syndrome caused by pituitary adrenocorticotropic hormone (ACTH) excess.

ICD-10CM CODES

E24 Cushing syndrome
E24.2 Drug-induced Cushing syndrome
E24.3 Ectopic ACTH syndrome
E24.8 Other Cushing syndrome
E24.9 Cushing's syndrome, unspecified
E24.9 Pituitary-dependent Cushing disease

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Hypertension
- Central obesity with rounding of the facies (moon facies); thin extremities. Fig. 1 illustrates the distribution of adipose tissue in Cushing syndrome
- Hirsutism, menstrual irregularities, hypogonadism
- Skin fragility, ecchymoses, red-purple abdominal striae (Fig. E2), acne, poor wound healing, hair loss, facial plethora, hyperpigmentation (with ACTH excess). The frequency of individual findings in Cushing syndrome is summarized in Table 1
- Psychosis, emotional lability, paranoia
- Muscle wasting with proximal myopathy

NOTE: The previous characteristics are not commonly present in Cushing syndrome caused by ectopic ACTH production. Many of these tumors secrete a biologically inactive ACTH that does not activate adrenal steroid synthesis. These patients may have only weight loss and weakness.

ETIOLOGY

- Iatrogenic from long-term glucocorticoid therapy (common).

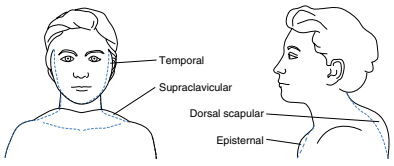

FIG. 1 Distribution of adipose tissue in Cushing syndrome. Rounding of the cheeks and prominent bitemporal fat produce the characteristic moon facies. Fat also may accumulate bilaterally above the clavicles (supraclavicular collar), in front of the sternum (episternal area, or dewlap), and over the back of the neck (dorsal cervical fat pad, or buffalo hump). In these drawings, the dotted line depicts normal contours of patients without Cushing syndrome. (From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.)

- Pituitary ACTH excess (Cushing disease; 60%).
- Adrenal neoplasms (30%).
- Ectopic ACTH production (neoplasms of lung, pancreas, kidney, thyroid, thymus; 10%).
- Table E2 summarizes the incidence of tumors associated with the ectopic adrenocorticotropic hormone syndrome.
- A classification of causes of Cushing syndrome is described in Table E3.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Alcoholic pseudo-Cushing syndrome (endogenous cortisol overproduction)
- Obesity associated with diabetes mellitus
- Adrenogenital syndrome

WORKUP

- Initial tests include the overnight low-dose dexamethasone suppression test (LDST), 24-hour urine free cortisol (UFC), and late-night (LN) salivary cortisol. The LN and UFC tend to be more convenient.
- Late-night salivary cortisol: A single midnight serum cortisol level (normal diurnal variation leads to a nadir around midnight) >7.5 mcg/dl has been reported as 96% sensitive and 100% specific for the diagnosis of Cushing syndrome. This test assesses the normal diurnal rhythm of cortisol (lost in Cushing syndrome) and is not useful in patients who have inconsistent sleep patterns or do shift work. It can also be affected by tobacco use and use of topical corticosteroids.
- In patients with a clinical diagnosis of Cushing syndrome, the classic initial screening test is the overnight dexamethasone suppression test:
  1. Dexamethasone 1 mg PO given at 11 PM.
  2. Plasma cortisol level measured 9 hr later (8 AM).
  3. Plasma cortisol level <5 mcg/100 ml excludes Cushing syndrome.
- Serial measurements (two or three consecutive measurements) of 24-hr urinary free cortisol and creatinine (to ensure adequacy of collection) are undertaken if overnight dexamethasone test is suggestive of Cushing syndrome. Persistent elevated cortisol excretion (>300 mcg/24 hr) indicates Cushing syndrome.
- The low-dose (2 mg) dexamethasone suppression test is useful to exclude pseudo-Cushing syndrome if the previous results are equivocal. Corticotropic-releasing hormone (CRH) stimulation after low-dose dexamethasone administration (dexamethasone-CRH test) is also used to distinguish patients with suspected Cushing syndrome from those who have mildly elevated urinary free cortisol level and equivocal findings.
- The high-dose (8 mg) dexamethasone test and measurement of ACTH by radioimmunoassay are useful to determine the etiology of Cushing syndrome.
  1. ACTH undetectable or decreased and lack of suppression indicate adrenal cause of Cushing syndrome.
  2. ACTH normal or increased and lack of suppression indicate ectopic ACTH production.
  3. ACTH normal or increased and partial suppression suggest pituitary excess (Cushing disease).
- Bilateral inferior petrosal sinus sampling (BIPSS) can be used to distinguish pituitary Cushing disease from the ectopic ACTH syndrome.

TABLE 1 Cushing Syndrome—Frequency of Individual Findings

Physical Finding†	Frequency (%)‡
Vital Signs	
Hypertension	64-88
Body Habitus	
Moon facies	67-92
Central obesity	44-97
Buffalo hump	34-75
Skin Findings	
Thin skin	27
Plethora	28-94
Hirsutism, women	48-81
Ecchymoses	23-75
Red or purple striae	46-68
Acne	21-52
Extremity Findings	
Proximal muscle weakness	39-68
Edema	15-66
Other	
Significant depression	12-40

†*Diagnostic standard*: For Cushing syndrome, elevated daily cortisol or corticosteroid metabolites, or both, with loss of circadian rhythm and with abnormal dexamethasone suppression tests.
‡Results are overall mean frequency or, if statistically heterogeneous, the range of values.
From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.

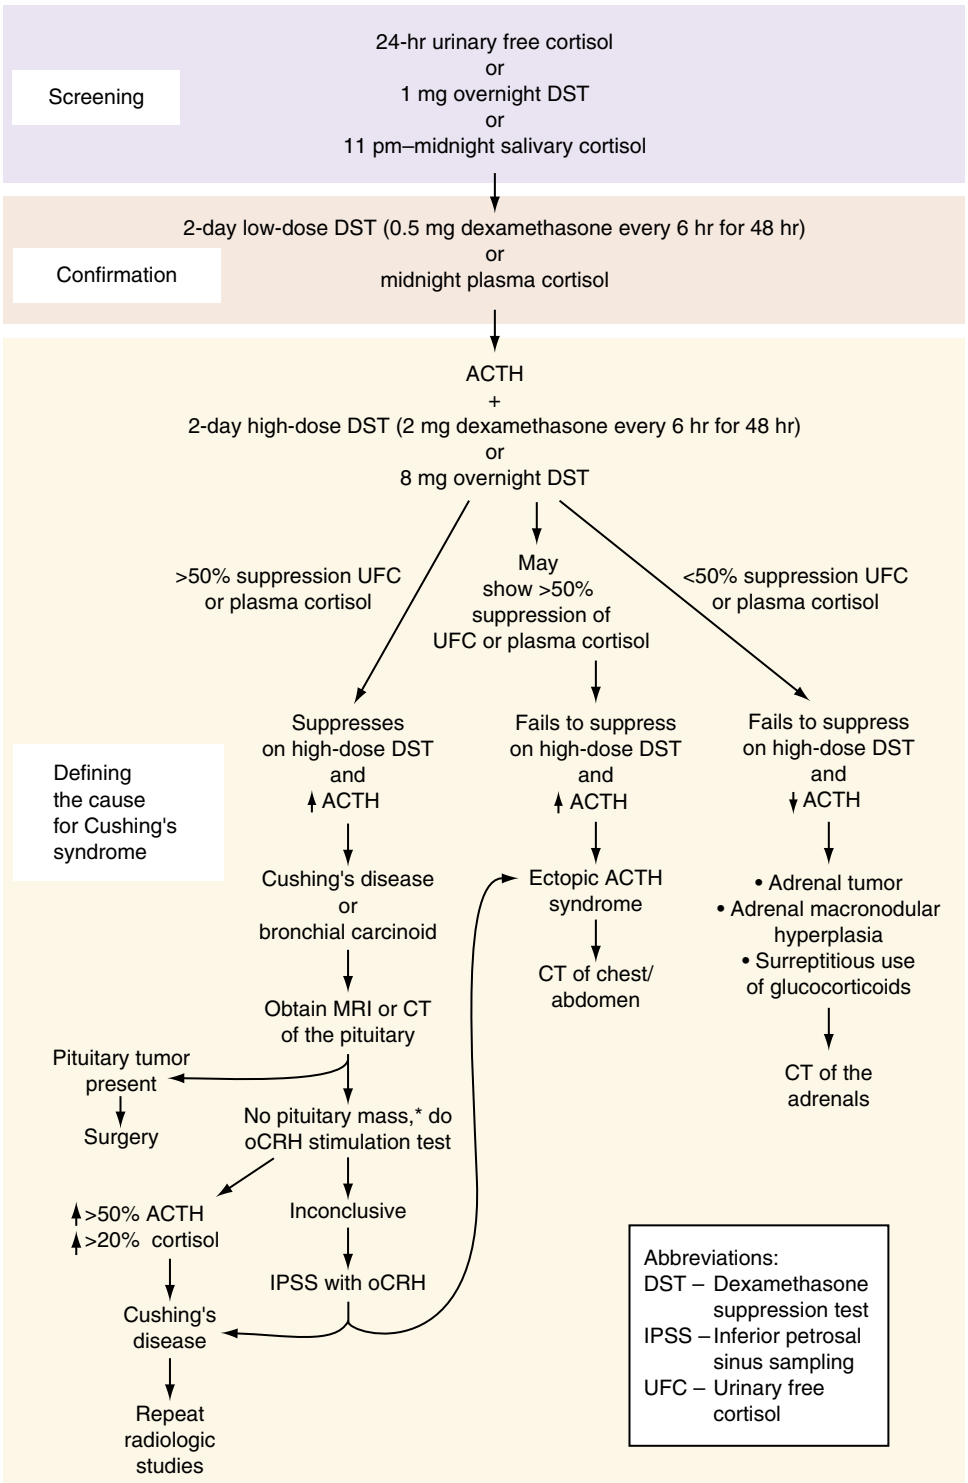

FIG. 3 Algorithm for the evaluation of Cushing syndrome. All screening tests must be followed by a confirmatory test. If there is no pituitary mass, obtain a chest radiograph and chest CT to rule out bronchial carcinoid before proceeding to IPSS. *ACTH,* Adrenocorticotropin; *CT,* computed tomography; *oCRH,* ovine corticotropin-releasing hormone; *MRI,* magnetic resonance imaging. (From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods,* ed 23, Philadelphia, 2017, Elsevier.)

LABORATORY TESTS

- Hypokalemia, hypochloremia, metabolic alkalosis, hyperglycemia, hypercholesterolemia.
- Increased 24-hr urinary free cortisol (>100 mcg/24 hr).
- Table 4 describes the differential diagnosis of hormonal values seen in Cushing syndrome.
- Fig. 3 describes an algorithm for the evaluation of Cushing syndrome.

IMAGING STUDIES

- CT scan or MRI of adrenal glands in suspected adrenal Cushing syndrome (Fig. E4).
- MRI of pituitary gland with gadolinium is the preferred procedure for localizing a pituitary edema in suspected pituitary Cushing syndrome.
- Additional imaging studies to localize neoplasms of the lung, pancreas, kidney, thyroid, or thymus in patients with ectopic ACTH production.

Rx TREATMENT

GENERAL Rx

The definitive treatment of Cushing syndrome is surgical removal of the tumor causing excessive production of cortisol:

- Pituitary adenoma: Transsphenoidal microadenomectomy is the therapy of choice in adults. Pituitary irradiation is reserved for patients not cured by transsphenoidal surgery. In children, pituitary irradiation may be considered as initial therapy because 85% of children are cured by radiation. Stereotactic radiotherapy (photon knife or gamma knife) is effective and exposes the surrounding neuronal tissues to less irradiation than does conventional radiotherapy. Total bilateral adrenalectomy is reserved for patients not cured by transsphenoidal surgery or pituitary irradiation

TABLE 4 Differential Diagnosis of Hormonal Values Seen in Cushing Syndrome

Cause	Plasma ACTH	Plasma Cortisol (PM)	High-Dose or Overnight Dexamethasone Suppression
Pituitary-dependent	N—slightly ↑	↑	Yes
Adrenal disease	↓—undetectable	↑	No
Ectopic Cushing*	↑↑↑	↑↑	Usually no
Pseudo-Cushing	N—slightly ↑	N–↑	Usually yes

ACTH, Adrenocorticotropin; *N,* normal.
*ACTH levels may overlap with values seen in pituitary-dependent disease.
From McPherson RA, Pincus MR (eds): *Henry's clinical diagnosis and management by laboratory methods,* ed 23, St Louis, 2017, Elsevier.

- Adrenal neoplasm:
  1. Surgical resection of the affected adrenal
  2. Glucocorticoid replacement for approximately 9 to 12 mo after the surgery to allow time for the contralateral adrenal gland to recover from its prolonged suppression
  3. In nonsurgical candidates, suppression of adrenal steroid production can be accomplished with ketoconazole. Mifepristone, an antiprogestin, can also be used for control of hyperglycemia secondary to hypercortisolism in adults with endogenous Cushing syndrome. It should be avoided in women who are or who could become pregnant
- Bilateral micronodular or macronodular adrenal hyperplasia: Bilateral total adrenalectomy
- Ectopic ACTH:
  1. Surgical resection of the ACTH-secreting neoplasm
  2. Control of cortisol excess with metyrapone, aminoglutethimide, mifepristone, or ketoconazole
  3. Control of the mineralocorticoid effects of cortisol and 11-deoxycorticosteroid with spironolactone
  4. Bilateral adrenalectomy: A rational approach to patients with indolent, unresectable tumors

DISPOSITION

Prognosis is favorable in patients with surgically amenable disease.

PEARLS & CONSIDERATIONS

COMMENTS

Screening for multiple endocrine neoplasia type I should be considered in patients with Cushing disease.

TABLE E3 Classification of Causes of Cushing Syndrome

ACTH-Dependent Causes
Cushing disease (pituitary-dependent)
Ectopic ACTH syndrome
Ectopic CRH syndrome
Macronodular adrenal hyperplasia
Iatrogenic (treatment with 1-24 ACTH)
ACTH-Independent Causes
Adrenal adenoma and carcinoma
Primary pigmented nodular adrenal hyperplasia and Carney syndrome
McCune-Albright syndrome
Aberrant receptor expression (gastric inhibitory polypeptide, interleukin-1β)
Iatrogenic (e.g., pharmacologic doses of prednisolone, dexamethasone)
Pseudo-Cushing Syndromes
Alcoholism
Depression
Obesity

ACTH, Adrenocorticotropic hormone; *CRH,* corticotropin-releasing hormone.
From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.

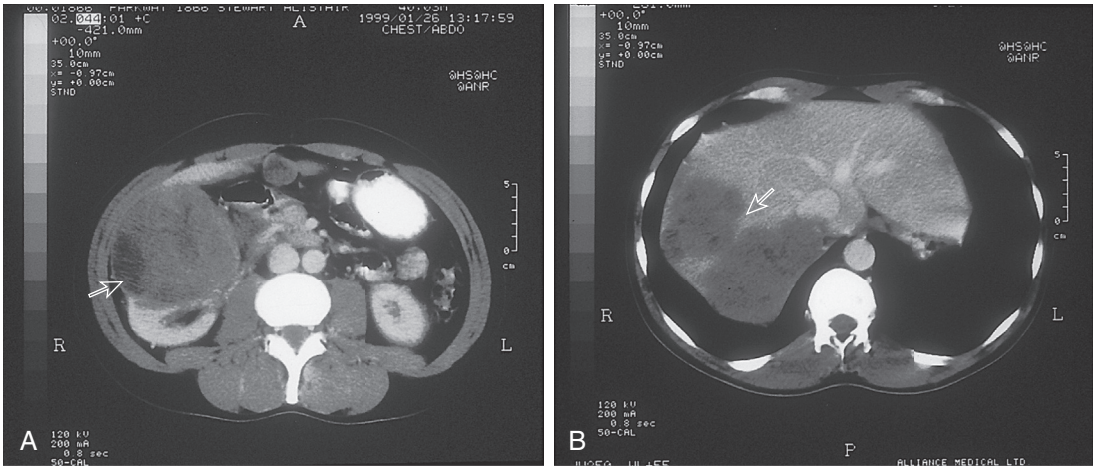

FIG. E4 Computed tomography scan of a patient with rapidly progressing Cushing syndrome caused by an adrenal carcinoma. An irregular right adrenal mass is shown **(A),** and a large liver metastasis is evident **(B).** (From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.)

BASIC INFORMATION

DESCRIPTION

Cutaneous larva migrans (CLM) is a syndrome defined clinically and parasitologically by subcutaneous larval migration of nematodes. Creeping eruption is the cardinal manifestation. It includes neither diseases in which creeping eruption is due to nonlarval forms of parasites nor diseases without creeping eruptions from subcutaneous migration of larval parasites. Because animal hookworms are the most common cause, some people use the term "hookworm-related cutaneous larva migrans" (HrCLM) instead. Table E1 describes other clinical syndromes associated with unusual helminth infections in humans.

SYNONYMS

CLM
Creeping eruption
Plumber's itch
Creeping verminous dermatitis
Sand worm eruption
Duck hunter's itch
Hookworm-related cutaneous larva migrans HrCLM

ICD-10CM CODES

B76.8	Other hookworm diseases
B76.9	Hookworm disease, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALANCE: Commonly seen in tropical and subtropical countries. In the U.S., it is most prevalent in southeastern states. Florida has the most cases among these states.
PREDOMINANT AGE: More often seen in children than adults.
GENETICS: Has no racial or sexual predilection.
PEAK INCIDENCE: Peak incidence is seen during rainy season.

- Second to pinworm among helminth infection in developed countries.
- Most common tropically acquired dermatosis.
- Most common imported ectoparasites in travelers returning to the U.S. after a holiday.

RISK FACTORS

Hobbies and occupations that involve contact with warm, moist, sandy soil:

- Tropical or subtropical climate travels
- Barefoot beach goers or sunbathers
- Children playing in sandboxes
- Carpenters, electricians, plumbers, farmers, gardeners, pest exterminators

ETIOLOGY

- Animal hookworms
- *Ancylostoma braziliense* (commonest cause)
- *Ancylostoma caninum*
- *Uncinaria stenocephala*
- *Bunostomum phlebotomum*
- *Pelodera strongyloides*
- *Gnathostoma* species
- *Strongyloides stercoralis*
- *Spirulina* species

PATHOGENESIS

The infection is usually acquired via skin contact with the soil or sand contaminated with feces of infected dogs or cats. The filariform larva is the infective form. It penetrates the skin and migrates within the epidermis by releasing protease and hyaluronidase. The inflammatory reaction along the cutaneous tract of their migration results in creeping eruptions. The larvae are believed to lack the collagenase enzymes required to penetrate the basement membrane to invade the dermis. In contrast to cats and dogs, humans are incidental host. Thus, the larvae are unable to complete their natural cycles in humans. The larvae die without treatment and are resorbed within weeks to months of invasion. This explains why CLM is a self-limiting disease and rarely has systemic features.

CLINICAL FEATURES

- Often associated with a history of sunbathing, walking barefoot on a beach, or similar activity in a tropical location.
- Incubation period is around 1 to 6 days.
- Intense pruritus at the site of invasion within hours of invasion.
- Many patients report a stinging sensation, which they may misinterpret as a puncture or insect bite.
- Erythematous papules develop at the larval penetration site. Feet, buttocks, and thighs are most commonly affected anatomical locations.
- The most frequent and cardinal finding of HrCLM is *creeping dermatitis*, which takes a few days to develop. It is defined as an erythematous, slightly elevated, linear, or serpiginous track that is 3 mm in width and may be up to 15 to 20 cm in length. The mean number of lesions per person varies from one to three. The creeping track associated with the larva migration may extend a few millimeters to few centimeters daily (Fig. E1). These eruptions last 2 to 8 wk without treatment.

TABLE E1 Clinical Syndromes Associated with Unusual Helminth Infections in Humans

Clinical Syndrome	Parasite	Usual Host
Visceral larva migrans	*Toxocara canis*	Canines
	Toxocara cati	Felines
	Baylisascaris procyonis	Raccoons
Eosinophilic gastroenteritis	*Anisakis* spp.	Sea mammals
	Phocanema spp.	Sea mammals
	Ancylostoma caninum	Canines
Cutaneous larva migrans	*Ancylostoma braziliense*	Canines, felines
	Ancylostoma caninum	Canines, felines
	Uncinaria stenocephala	Canines, felines
Eosinophilic meningitis	*Angiostrongylus cantonensis*	Rats
	Gnathostoma spinigerum	Felines, other mammals
Pulmonary or cutaneous nodules	*Dirofilaria* spp.	Canines, other mammals
Abdominal angiostrongyliasis	*Angiostrongylus costaricensis*	Cotton rats
Capillariasis	*Capillaria philippinensis*	Birds
Diarrhea	*Nanophyetus salmincola*	Mammals, birds
Swimmer's itch	*Trichobilharzia* spp.	Birds

FIG. E1 Cutaneous larva migrans characterized by a serpiginous erythematous migratory lesion caused by an infection with dog hookworm. (Courtesy Dr. Timothy Berger, San Francisco. In Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

- Edema and vesicobullous lesions along the course of the larva.
- Rare presentation is hookworm folliculitis. It is characterized by numerous (20 to 100) follicular, erythematous, and pruritic papules and pustules, located mainly in the buttocks. Generally numerous short tracks are seen arising from these follicular lesions.
- In case of rare pulmonary involvement, dry cough and wheezing develop 1 wk after the dermal invasion.

Dx DIAGNOSIS

Diagnosis is made on clinical grounds and history of potential exposure. Clinical characteristics of the creeping trails (length, width, speed of migration, location, duration) help differentiate HrCLM from other causes of creeping dermatitis.

- Blood tests are not necessary for diagnosis. Theoretically, blood test could detect eosinophilia and elevated IgE level.
- Biopsy specimens usually show an eosinophilic inflammatory infiltrate but not the migratory parasite. For this reason, biopsy is not indicated to establish the diagnosis. Nonetheless, in case of hookworm folliculitis, skin biopsy specimens may reveal nematode larvae in the follicular canal.
- Stool studies and serology are not helpful.
- Radiography of the chest is indicated when migratory pulmonary infiltrates are suspected.
- A new technology, optical coherence tomography, has been found to identify the larvae in the epidermis, allowing direct removal.

DIFFERENTIAL DIAGNOSIS

- Superficial thrombophlebitis
- Mondor disease
- Lichen striatus
- Phytophotodermatitis
- Herpes zoster
- Migratory myiasis
- Scabies
- Loiasis
- Dracunculiasis
- Cercarial dermatitis
- Onchocerciasis
- Dirofilariasis
- Contact dermatitis
- Creeping hair
- Jelly fish stings
- Fascioliasis
- Bacterial folliculitis
- Tinea pedis/corporis
- Impetigo
- Erythema chronicum migrans of Lyme disease
- Ground itch
- Toxocariasis

Rx TREATMENT

- Oral albendazole and ivermectin are the first-line drug treatments.
- Oral administration is preferred in the presence of extensive lesions or when topical application fails.
- Topical application should cover the tracks and area covering up to 2 cm from the leading edge.
- Albendazole should be given (400 mg orally per day for 3 to 5 days).
- At times, when oral drugs are contraindicated, topical 10% albendazole creams are applied twice a day for a period of 10 days.
- Ivermectin should be given (200 mcg/kg given as a single dose).
- Thiabendazole should be given (25 to 50 mg/kg divided into twice-daily doses for 2 days).
- Because of its higher side effect profile when given orally, it is more often applied topically (10% to 15% cream or aqueous suspension of 500 mg/5 ml) four times a day for 5 to 10 days.
- Mebendazole should be given (100 mg orally twice for 3 days).
- Cryotherapy with liquid nitrogen is obsolete. It is ineffective as the larva is usually located 1 to 2 cm beyond the visible end of the trail, and the larva is capable of withstanding temperature as low as –21° C (–5º F) for more than 5 minutes. Moreover, this procedure is painful and can lead to chronic ulcerations.
- Specific antihelmintic therapy for pulmonary involvement is generally not required because the illness is usually mild and self-limiting.
- In the case of hookworm folliculitis, treatment is more difficult than the traditional form and necessitates repeated courses of oral antihelmintic agents.
- Antihistamines and topical steroids relieve intense pruritus.
- Antibiotics are indicated for bacterial superinfection.
- Generally, there should be no attempt to extract the worm.

COMPLICATIONS

- Secondary bacterial infection
- Erythema multiforme
- Migratory eosinophilic pneumonitis (Loeffler syndrome)
- Eosinophilic enteritis

PROGNOSIS

Self-limiting benign disease. Even without treatment, most cases resolve within 4 to 8 wk.

PREVENTION

- Prohibit pets such as dogs and cats walking on the beaches in tropical areas.
- Avoid allowing pets in sandboxes.
- Deworm household pets.
- Clean up pet droppings.
- Wear protective footwear while walking on the beach.
- Avoid tropical beaches frequented by dogs and cats.
- When lying on tropical beaches potentially frequented by dogs and cats, areas of sand washed by the tide are preferable to dry sand, and mattresses are preferable to towels.
- Towels and clothes should not touch the ground when hung up for drying.

AUTHOR: **Hemant K. Satpathy, MD**

BASIC INFORMATION

DEFINITION

Blue or purple skin discoloration due to increased circulating levels of deoxygenated blood

SYNONYMS

Methemoglobinemia
Sulfhemoglobinemia
Acrocyanosis
Pseudocyanosis

ICD-10CM CODES

R23.0	Cyanosis
P28.2	Cyanotic attacks of the newborn
I73.8	Acrocyanosis
I73.89	Other specified peripheral vascular diseases

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PEAK INCIDENCE: Unknown
PREVALENCE: Unknown
PREDOMINANT SEX AND AGE: Unknown
GENETICS: None
RISK FACTORS: Congenital heart disease, high altitude, hypercoagulable state, cardiopulmonary disease, cirrhosis, exposure to aniline dyes, lidocaine use

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History: Onset; time of day of symptoms; prior episodes of cyanosis; recent medication use; associated symptoms, including fever or cough; past medical history (PMHx) of congenital heart disease, cardiopulmonary disease, neurologic condition that results in decreased respiratory effort including seizures, breath-holding spells; family history of congenital heart disease
- Physical examination: Bluish discoloration of perioral skin, conjunctivae, and oral mucosa suggests central cyanosis; peripheral cyanosis will result in discoloration of extremities and nail beds; trauma to chest wall or upper airway may cause central cyanosis due to lung injury or obstruction; tachypnea and retractions are seen in patients with respiratory causes of cyanosis, as well as abnormal lung examination findings (wheezes, crackles); tachycardia frequently accompanies cyanosis in children; bradycardia in the setting of cyanosis can indicate pending circulatory collapse

ETIOLOGY

Various causes are responsible for this clinical finding (see "Differential Diagnosis"). Investigation for the underlying cause is critical to determining appropriate treatment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Cyanosis should be separated into central or peripheral causes to guide the differential diagnosis.

Central cyanosis

- Decreased arterial O_2 saturation
  1. Decreased atmospheric pressure—high altitude
  2. Impaired pulmonary function—hypoventilation, V/Q mismatch, impaired O2 diffusion
- Anatomic shunts—fistulae (cerebral, pulmonary, hepatic, peripheral), cyanotic congenital heart disease
- Hemoglobin with low O_2 affinity
- Hemoglobin abnormalities—methemoglobinemia (hereditary), sulfhemoglobinemia (acquired), carboxyhemoglobinemia (not true cyanosis)

Peripheral cyanosis

- Low cardiac output states (cardiogenic shock, hypovolemia with or without bleeding, sepsis)
- Environmental exposures: Air, water
- Arterial occlusion: Thrombosis, embolism, vasospasm (Raynaud), peripheral vascular disease
- Venous obstruction
- Redistribution of blood flow from extremities
- Cyanide-related nitroprusside toxicity (initially, skin may be "cherry red" due to increased venous hemoglobin levels, progressing to cyanosis that accompanies shock)

WORKUP

- Fig. E1 outlines the approach to a patient with central cyanosis. The evaluation of peripheral cyanosis is summarized in Fig. E2.
- Examine patient's circulation/airway/breathing (CAB) and arterial blood gas (ABG), administer supplemental O_2; if concern for shock or patient otherwise unstable, obtain emergency medical services immediately for management of airway and breathing as needed, as well as for additional evaluation of shock (hypovolemic, septic, cardiogenic).
- If improvement with O_2, obtain chest x-ray to evaluate cardiac silhouette:
  1. Normal cardiac silhouette suggests decreased pulmonary function from infiltrates, effusion, edema, pulmonary embolism (PE), or arteriovenous fistulae.
  2. Enlarged cardiac silhouette may suggest cardiogenic shock; obtain electrocardiogram or echocardiogram to further evaluate.
  3. If no improvement with supplemental O_2 (PaO_2 <100 or SaO_2 <70), obtain chest x-ray and methemoglobin, carbon monoxide, and cyanide levels.
  4. If respiratory distress, evaluate for pneumothorax, upper airway obstruction, or bronchospasm.
  5. If no respiratory distress, evaluate for chronic methemoglobinemia, sulfhemoglobinemia, G6PD deficiency, or cyanotic heart disease.

LABORATORY TESTS

- Deoxygenated hemoglobin in the capillary blood is elevated to ≥5 g/dl
- Complete blood count to evaluate for erythrocytosis, polycythemia, or anemia
- D-dimer if pulmonary embolism is suspected
- Peripheral smear to look for red blood cell count morphology and fragments
- Thiocyanate levels if suspected nitroprusside toxicity

IMAGING STUDIES

- Chest x-ray to evaluate for new pulmonary infiltrates, effusions, edema, or consolidations
- ECG for those with abnormal cardiac examination findings
- Echocardiography for infants and children with suspected congenital heart disease
- Compression ultrasonography of lower extremity or chest computed tomography angiography if deep venous thrombosis or PE suspected as cause for cyanosis

TREATMENT

NONPHARMACOLOGIC THERAPY

Decontamination with soap and water after discontinuing offending agent

ACUTE GENERAL Rx

- Administer high-flow oxygen first and monitor response in all patients
- Methylene blue (1 to 2 mg/kg IV over 5 minutes) if patients have symptomatic hypoxia or methemoglobin level >30% in methemoglobinemia
- Phlebotomy and crystalloid fluid expansion to achieve hematocrit <45% if polycythemia
- Elevate head of bed and oxygen for superior vena cava syndrome; radiation/chemotherapy/vascular stenting if caused by malignancy
- Intravenous fluid resuscitation if hypovolemia is present
- Cyanotic patients with altered mental status often have decreased oxygen saturation due to disordered breathing or neuromuscular weakness causing respiratory depression. Such patients typically cannot maintain their airway and will require advanced airway support unless their underlying cause of coma can be treated rapidly (dextrose for hypoglycemia, naloxone for opiod overdose, benzodiazepine for seizures). Transient central cyanosis is a common feature of breath-holding spells and seizures
- Provide guideline-directed medical therapy for congestive heart failure, arrhythmias, or poor cardiac output
- Supportive care and antidotes if toxin-mediated cyanosis is present

DISPOSITION

- Admit patients with first episode or unexplained cyanosis
- Discharge patients with peripheral cyanosis from vasoconstriction, methemoglobin <15%, and primary pulmonary disease

REFERRAL

- Pediatric cardiology if children have first episode of congestive heart failure or newly diagnosed congenital heart disease as suggested by abnormal ECG and/or chest radiograph findings

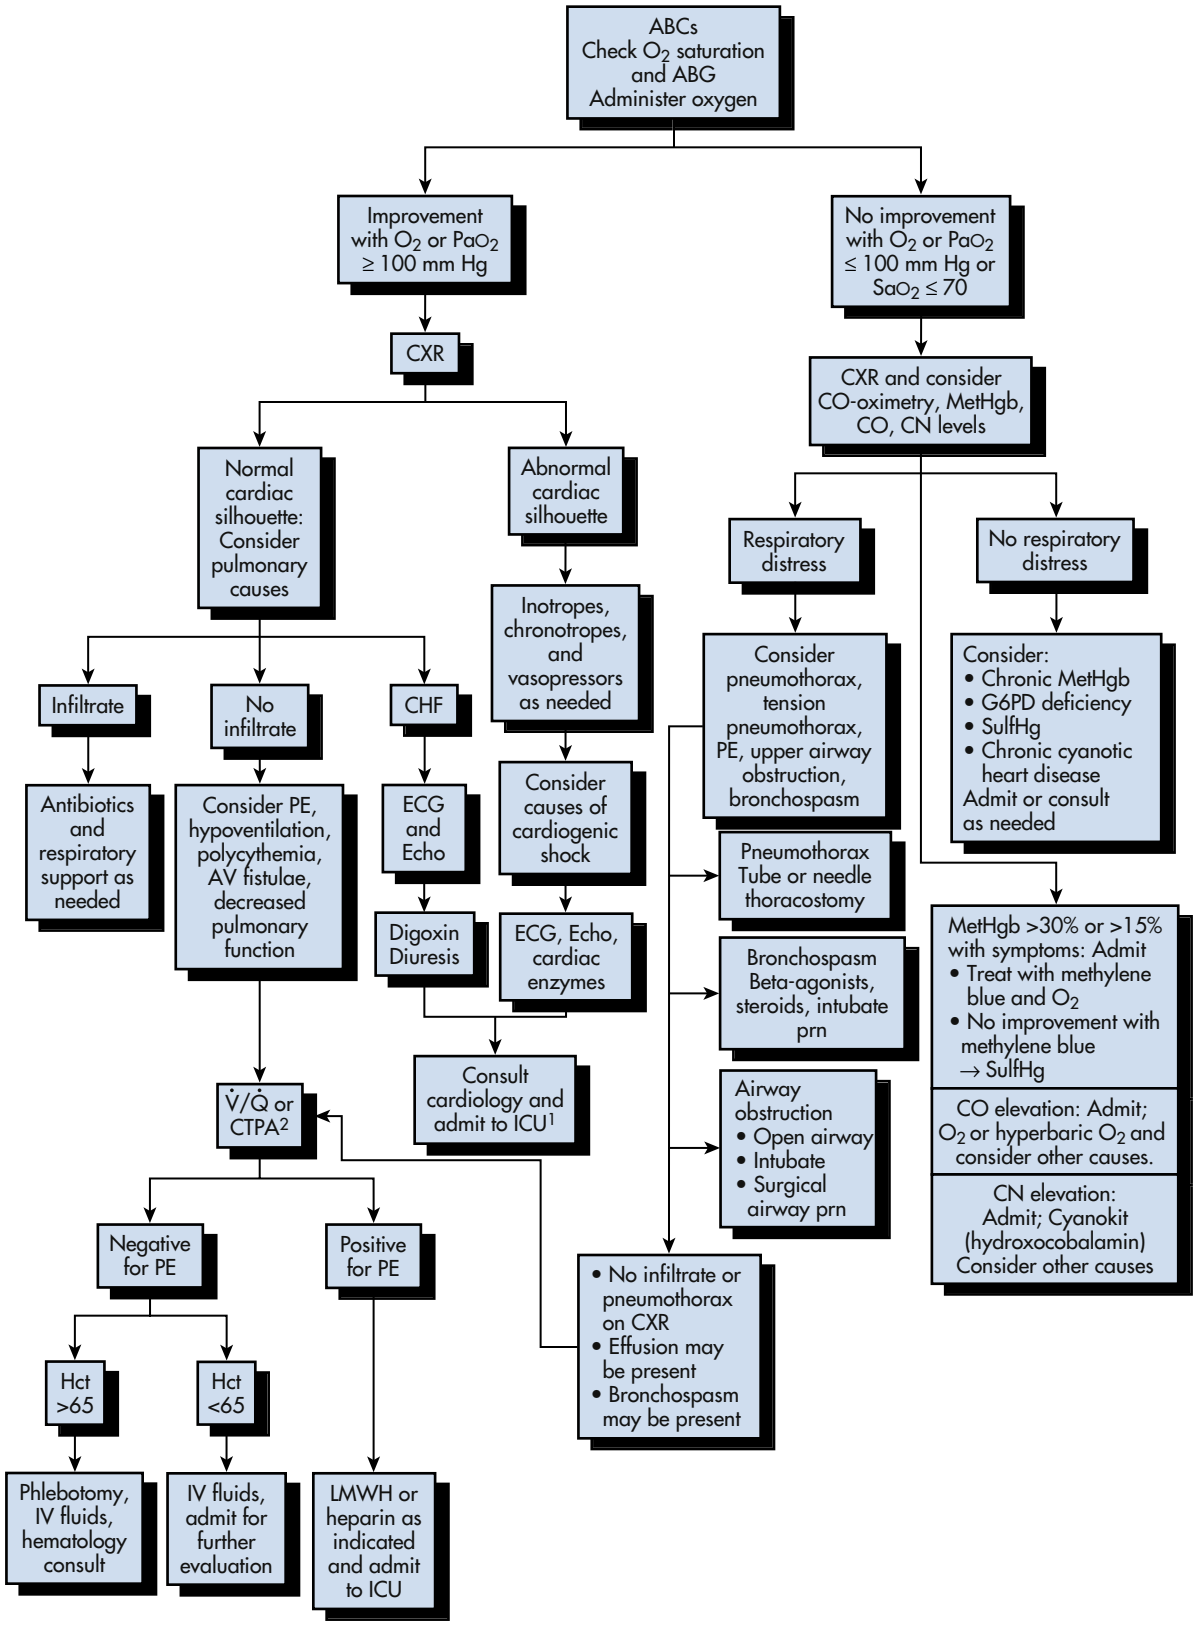

FIG. E1 Approach to central cyanosis. *ABCs*, Airway, breathing, circulation; *ABG*, arterial blood gas; *CHF*, congestive heart failure; *CN*, cranial nerve; *CO*, carbon monoxide; *CTPA*, computed tomography pulmonary angiogram; *CXR*, chest x-ray; *Echo*, echocardiogram; *ECG*, electrocardiogram; *Hct*, hematocrit; *ICU*, intensive care unit; *IV*, intravenous; *LMWH*, low-molecular-weight heparin; *MetHgb*, methemoglobin; *PE*, pulmonary embolism; *prn*, as needed; *V/Q*, ventilation/perfusion. (From Walls RM, Hockberger RS, Gausche-Hill M: *Rosen's emergency medicine: concepts and clinical practice,* ed 9, Philadelphia, 2018, Elsevier.)

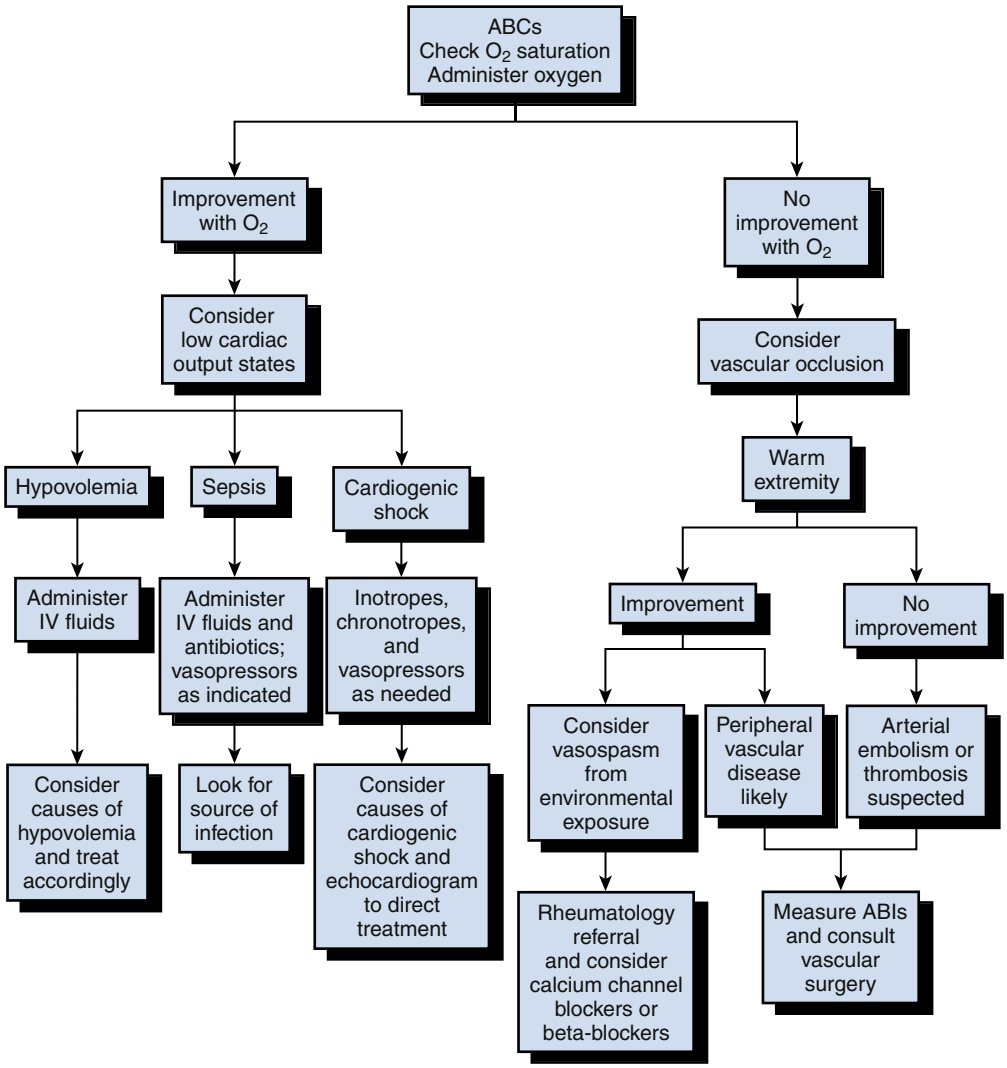

FIG. E2 Approach to peripheral cyanosis. *ABCs*, Airway, breathing, circulation; *ABI*, ankle-brachial index; *IV*, intravenous. (From Walls RM, Hockberger RS, Gausche-Hill M: *Rosen's emergency medicine: concepts and clinical practice,* ed 9, Philadelphia, 2018, Elsevier.)

- Congenital vascular surgery evaluation if acute arterial occlusion is suspected or confirmed
- Suspected intensive care unit and/or cardiology assessment if cyanosis is due to acute cardiovascular or pulmonary collapse from shock
- Consider rheumatology for Raynaud phenomenon to assess for systemic autoimmune disorder

PEARLS & CONSIDERATIONS

- In all patients with cyanosis, evaluate CAB, O_2 saturation, and ABG; provide supplemental O_2 to all patients with cyanosis.
- An increase in PaO_2 >100 or resolving cyanosis suggests oxygen diffusion defect.
- All patients with new-onset or unexplained cyanosis require hospitalization.
- Methylene blue in patients with methemoglobinemia if levels >30% or symptomatic hypoxia.
- Failure of methemoglobinemia to improve with methylene blue indicates sulfhemoglobinemia.
- In infants with or who have a clinical suspicion for a ductal-dependent congenital heart defect, prostaglandin E1 (alprostadil) should be administered until a definitive diagnosis or treatment is established.

PREVENTION

- Avoid offending agents.
- Avoid excessive exposure to cold air or water.

PATIENT & FAMILY EDUCATION

- Avoid excessive exposure to cold air or water if diagnosed with Raynaud phenomenon.
- Return to the emergency department if cyanosis is accompanied by dyspnea, altered mentation, or chest pain.

AUTHOR: **Juan Guerra, DO**

Cyclic Vomiting Syndrome

BASIC INFORMATION

DEFINITION

Cyclic vomiting syndrome (CVS), an idiopathic disorder primarily seen in children, is characterized by recurrent, stereotypical episodes of vomiting with varying asymptomatic periods.

SYNONYM

CVS

ICD-10CM CODES
G43.A0 Cyclical vomiting, not intractable
G43.A1 Cyclical vomiting, intractable

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE & PREVALENCE:

- Cross-sectional study of school-age children in Aberdeen, Scotland, estimated that 1.6% fulfilled diagnostic criteria.
- Average age of time of diagnosis: 9.6 yr.
- Average age of onset of symptoms: 5.3 yr.
- This study showed gender ratio was equivalent, although isolated reports say it may be more common in girls.
- In adults, no population studies exist to extrapolate prevalence. In one study with 17 patients followed over a 10-yr interval, it was found that average age of onset was 35 yr, but diagnosis was 41 yr. Gender distribution was again found to be equal.

GENETICS: Mutations in mitochondrial DNA (mtDNA) have been associated with cyclical vomiting syndrome and neuromuscular disease in pediatric patients. These mutations were also more commonly associated with migraines, irritable bowel syndrome, and hypothyroidism. Evidence shows that the mtDNA mutations seen in pediatric patients have a maternal inheritance pattern.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- There is a stereotypical pattern to the vomiting episodes. They normally begin in the early morning hours and may involve a prodrome that includes pallor, nausea, abdominal pain, or lethargy.
- High rates of emeses per hour with the peak in the first hour with a decline in the next 4 to 8 hr. These episodes normally last up to 24 hr.
- Many patients may have neurologic symptoms, including headache, photophobia, or vertigo, which supports the genetic relation between CVS and migraines.

ETIOLOGY

- mtDNA mutations that were also associated with migraines in pediatric patients with two mtDNA polymorphisms in particular, 16519T and 3010A, that are expressed in high frequency in subjects with CVS. In adults, CVS is not associated with these polymorphisms.
- Sympathetic hyperresponsiveness and autonomic dysregulation may contribute to the pathogenesis of CVS. Elevated corticotropin, cortisol, vasopressin, and catecholamines have been described in patients with vomiting, lethargy, and hypertension. Studies in animals suggest that corticotropin-releasing factor induces gastric stasis, leading to emesis. Stress responses, which are mediated by the hypothalamic-pituitary-adrenal axis, can therefore potentially induce episodes of vomiting. Triggers of stress responses can be infectious, psychological, or physical.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute porphyria
- Abdominal migraines
- Diabetic ketoacidosis
- *Helicobacter pylori* infection
- Cannabis hyperemesis syndrome
- Jamaican vomiting sickness
- Munchausen syndrome by proxy
- Mechanical obstruction
- Gastrointestinal malignancies
- Intestinal malrotation

WORKUP

- CVS is a clinical diagnosis because there are no biochemical markers or imaging that exist to make the diagnosis. The North American Society of Pediatric Gastroenterology, Hepatology, and Nutrition (NASPGHAN) has set forth criteria (all criteria must be met). Box E1 summarizes criteria. In adults, Rome IV criteria should be met to make diagnosis. Box E2 summarizes Rome IV criteria. Supportive criteria in addition to either set of guidelines include a personal or family history of migraine headaches. Rome IV also divides patients with prolonged excessive cannabis use from CVS into cannabinoid hyperemesis syndrome (CHS). It also differentiates chronic nausea vomiting syndrome from CVS by distinct temporal characteristics of weekly acute episodes.
- All patients with suspected CVS should be questioned about cannabis use to rule out cannabis hyperemesis syndrome.

SUPPORTIVE CRITERION

History or family history of migraine headaches

LABORATORY TESTS

In the evaluation for possible GI disease as an etiology of vomiting, screening blood work should be performed. CBC, basic metabolic panel (BMP), liver function tests, pancreatic amylase and lipase, and erythrocyte sedimentation rate (ESR) should be done. Screening for endocrine and metabolic disorders is also warranted and can include lactic acid, ammonia, amino acids, adrenocorticotropic hormone (ACTH), and antidiuretic hormone (ADH) as well as urinary ketones, organic acids, porphobilinogen, and aminolevulinic acid. Drug screening should also be considered if CHS is a possibility.

IMAGING STUDIES

An upper GI series with small bowel follow-through, CT/MRI of the head, and endoscopy should be performed in between episodes. In adults, a CT of the abdomen and pelvis should be done in addition to the mentioned testing to exclude malignancy. Additional testing may include antroduodenal manometry to assess for neuropathy or myopathy, esophageal pH testing to rule out vomiting as an atypical presentation of GERD, and CT of head to rule out space-occupying lesions.

TREATMENT

- Treatment of CVS includes avoidance of certain triggers that precipitate attacks as well as pharmacologic therapy divided into prophylactic, abortive, and supportive treatment.
- Patients with regular use of cannabis should be asked to abstain for a short period and if symptoms resolve or improve then cannabis hyperemesis syndrome is likely.

NONPHARMACOLOGIC THERAPY

- Avoidance of dietary triggers such as chocolate, cheese, or monosodium glutamate (MSG) may prevent episodes.
- Stress management techniques for psychosocial stressors may decrease the frequency of episodes exacerbated by stress.

ACUTE GENERAL Rx

Treatment can be considered as prophylactic, abortive, or supportive.

- Prophylactic therapy is reserved for patients who have more than one attack per month or with attacks that are severe enough to cause hospitalization. A trial of prophylactic antimigraine medications is recommended even in the absence of personal or family history of migraine headaches. Prophylactic therapy includes cyproheptadine, amitriptyline, propranolol, erythromycin, and topiramate. Some specialists recommend starting amitriptyline at 0.5 mg/kg per day in children older than 5 yr. It often is increased to 1 mg/

Box E1 North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition (NASPGHAN) Criteria for Cyclic Vomiting Syndrome

- At least five episodes over any interval or a minimum of three attacks over a 6-mo period
- Episodic attacks of intense nausea and vomiting lasting from 1 hour to 10 days and occurring at least 1 wk apart
- Stereotypical in the individual patient
- Vomiting during attacks occurs at least four times per hour for at least 1 hour
- A return to baseline health between episodes

Box E2 Rome IV Diagnostic Criteria for Cyclic Vomiting Syndrome

Must include all of the following:
- Stereotypical episodes of vomiting regarding onset (acute) and duration (<1 wk)
- At least two acute-onset episodes in the past 6 mo, each occurring at least 1 wk apart and persisting less than 1 wk
- Absence of nausea and vomiting between episodes but other, milder symptoms can occur between cycles

kg per day, with effects typically taking a few months to become evident.
- There is emerging evidence that carnitine and coenzyme Q10 along with strict dietary protocol can reduce episodes.
- Abortive therapy is used during episodes. Agents that are used in migraine attacks such as triptans have also been found to be effective in aborting episodes in CVS. If abortive therapy fails, antiemetic therapy with ondansetron can be used as supportive therapy. If attack is severe, ondansetron may be used in conjunction with a benzodiazepine or diphenhydramine.

DISPOSITION

If episode is severe, the patient may need hospital admission. Treatment includes IV fluids, antiemetics, and analgesics. Otherwise, this can be managed on an outpatient basis.

REFERRAL

Referral should be made to a gastroenterologist for thorough investigation of vomiting until definitive diagnosis of CVS can be established. If certain neurologic findings or laboratory study results suggest a metabolic disorder, early referral to a metabolic specialist or neurologist should be considered.

PEARLS & CONSIDERATIONS

COMMENTS

CVS is a clinical diagnosis that is seen in pediatric and adult populations. Laboratory testing and appropriate imaging should be done to rule out other differential diagnoses. A thorough history including family history, onset and duration of episodes, alarming symptoms, and so on as well as a complete physical examination will allow clinician to narrow differential diagnoses.

PREVENTION

There is emerging evidence of carnitine and coenzyme Q10 in a certain subtype of patients to prevent frequent attacks. Prophylactic therapy includes pharmacologic agents stated earlier. Avoidance of stress and dietary triggers are also warranted if this can be identified as causative etiology.

PATIENT & FAMILY EDUCATION

Families are encouraged to view https://.cvsaonline.org for more information and education about the disease.

Cystic Fibrosis PTG ALG

BASIC INFORMATION

DEFINITION

Cystic fibrosis (CF) is an autosomal recessive disorder characterized by dysfunction of chloride channels of exocrine glands.

ICD-10CM CODES

- E84.0 Cystic fibrosis with pulmonary manifestations
- E84.11 Meconium ileus in cystic fibrosis
- E84.19 Cystic fibrosis with other intestinal manifestations
- E84.8 Cystic fibrosis with other manifestations
- E84.9 Cystic fibrosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- CF is the most common fatal hereditary disorder among Caucasians of Northern European descent in the U.S. (one case per approximately 3000) and the second most common life-shortening childhood-onset inherited disorder in the U.S., behind sickle cell disease.
- Worldwide it affects 80,000 children and adults.
- Median age at diagnosis is 5.3 mo. Median survival is now greater than 40 yr due to advancements in treatment.
- Carrier screening is associated with a decrease in incidence of CF.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Meconium ileus
- Failure to thrive in children
- Increased anterior/posterior chest diameter
- Basilar crackles and hyperresonance to percussion
- Digital clubbing
- Chronic cough
- Abdominal distention
- Greasy, foul-smelling feces
- Clinical manifestations of CF are summarized in Box E1
- The frequency of selected GI manifestations in CF is summarized in Table E1
- See Box E1

ETIOLOGY

CF is an autosomal-recessive disease caused by mutations to the gene encoding for the CFTR protein on chromosome 7; over gene mutations organized into six classes (Table E2) have been associated with CF. About half of patients in the U.S. with CF are homozygous for the Phe508del mutation in *CFTR*, and more than 90% have at least one Phe508del allele. These mutations result in abnormalities in chloride transport and thus water flux across the surface of epithelial cells (Fig. E1); the resulting abnormally viscous secretions cause obstruction of glands and ducts in various organs and subsequent damage to exocrine tissue (recurrent pneumonia, atelectasis, bronchiectasis, diabetes mellitus, biliary cirrhosis, cholelithiasis, intestinal obstruction, increased risk of gastrointestinal malignancies).

BOX E1 Clinical Manifestations of CF

Upper Respiratory
Sinusitis
Mucous membrane hypertrophy, nasal polyposis

Lower Respiratory
Atelectasis
Emphysema
Infections
Bronchitis, bronchopneumonia, bronchiectasis, lung abscess
Respiratory failure, right-sided heart failure

GI
Bile salt deficiency
Pancreatic insufficiency
GERD
PUD
Meconium ileus
Volvulus
Peritonitis
Ileal atresia
Distal intestinal obstruction syndrome
Fecal masses
Intussusception
Rectal prolapse

Pancreatic
Pancreatitis
Nutritional failure
Diabetes mellitus
Calcification
Maldigestion with steatorrhea and azotorrhea
Vitamin deficiencies

Hepatobiliary
Mucus hypersecretion
Gallstones, atrophic gallbladder
Focal biliary cirrhosis
Portal hypertension ± esophageal varices
Hypersplenism

Reproductive
Females: Increased viscosity of vaginal mucus, decreased fertility
Males: Sterility; absent ductus deferens, epididymis, and seminal vesicles

Skeletal
Retardation of bone age
Demineralization
Hypertrophic pulmonary osteoarthropathy

Ophthalmologic
Venous engorgement
Retinal hemorrhage

Other
Salt depletion through excessive loss of salt through skin
Heat stroke
Hypertrophy of apocrine glands

GERD, Gastroesophageal reflux disease; *GI,* gastrointestinal; *PUD,* peptic ulcer disease.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fortran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E1 Frequency of Selected GI Manifestations in CF*

Organ	Manifestation	Frequency in All Patients (%)	Frequency in Adults (%)
Pancreas	Total achylia	85-90	85-90*
	Abnormal glucose tolerance	20-30	20-30
	Partial or normal function	10-15	10-15
	Pancreatitis	1-2 (all CF) 22 (PS-CF)	2-3
	Diabetes mellitus	4-7	4-7
Intestine	Meconium ileus	10-25	
	Rectal prolapse	1-2	
	Distal intestinal obstruction syndrome	3	18
	Intussusception	1	1-2
Liver	Fatty liver	7	20-60
	Focal biliary cirrhosis	2-3	11-70
	Portal hypertension	2-3	28
Biliary tract	Gallbladder abnormal, nonfunctional, or small	25	5-20
	Gallstones	8	10-25
	Bile duct strictures	1-20	1-20
Esophagus	GERD	Unknown	80

CF, Cystic fibrosis; *GERD,* gastroesophageal reflux disease; *PS-CF,* CF with pancreatic sufficiency.
*Frequency may depend on the genotype.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Immunodeficiency states
- Celiac disease
- Asthma
- Recurrent pneumonia
- Primary ciliary dyskinesia

WORKUP

A diagnosis of CF requires proof of both CFTR dysfunction (i.e., elevated sweat chloride ≥60 mmol/L measured twice, two disease-causing mutations

TABLE E2 Classes of Cystic Fibrosis Transmembrane Conductance Regulator Mutations

Class	Effect on CFTR	Functional CFTR	Presence of CFTR on Cell Membrane
I	Defective protein production due to premature termination of CFTR messenger RNA	No	No
II	Impaired protein processing due to misfolding (e.g., ΔF508 deletion)	No	No, CFTR is degraded in the cytoplasm
III	Defective regulation with reduced channel opening time (e.g., G551D mutation)	No	Yes
IV	Impaired function causing reduced chloride transport	Yes, but reduced in function	Yes
V	Reduced synthesis of normally functioning CFTR	Yes, but reduced in number	Reduced in number
VI	Impaired membrane insertion or stability	Yes, but reduced in number	Reduced in number

CFTR, Cystic fibrosis transmembrane conductance regulator; *RNA,* ribonucleic acid.
From Weinberger SE: *Principles of pulmonary medicine*, ed 7, Philadelphia, 2019, Elsevier.

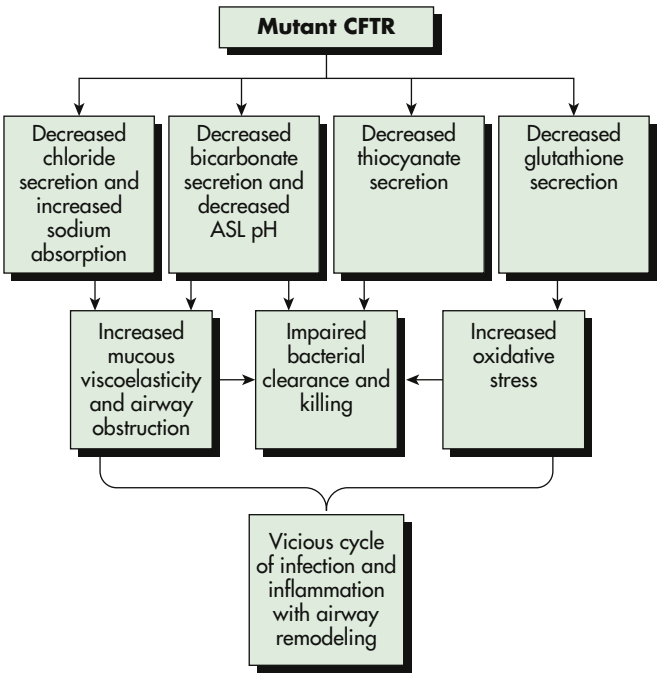

FIG. E1 Schema of mutant cystic fibrosis transmembrane conductance regulator (CFTR) mechanisms of chronic airway disease. CFTR conducts several anions including chloride, bicarbonate, thiocyanate, and glutathione. The loss of CFTR function impacts critical airway epithelial functions: (1) It increases the risk for dehydration of airway surface liquid (ASL) with loss of chloride efflux and associated increased sodium channel activity. (2) The loss of secreted bicarbonate and/or acidic pH of the ASL increases mucous viscoelasticity, resulting in failure of mucociliary transport. (3) Acidic pH in the ASL impairs normal innate immune clearance of bacteria. (4) Loss of thiocyanate impairs lactoperoxidase bacterial killing. (5) Loss of glutathione secretion depletes the antioxidant capacity of the airway, resulting in increased inflammation, increased mucous secretion, and increased mucous viscoelasticity. These factors lead to a vicious cycle of infection and inflammation that is progressive. *ASL,* Airway surface liquid; *CFTR,* cystic fibrosis transmembrane conductance regulator. (From Kliegman, RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.)

in CFTR from each parental allele, or abnormal nasal potential difference) and one or more phenotypic features consistent with CF (e.g., chronic suppurative obstructive lung disease, pancreatic insufficiency). Table E3 describes diagnostic criteria for CF. Conditions suggesting the diagnosis of CF in adults and recommended diagnostic studies are described in Table E4.

LABORATORY TESTS

- Pilocarpine iontophoresis (sweat chloride test): Diagnostic of CF in children if sweat chloride is >60 mmol/L (>80 mmol/L in adults) on two separate tests on consecutive days. Repeat testing may be necessary because not all infants have sufficient quantities of sweat for reliable testing. Indications for sweat test and conditions with associated high electrolyte levels are summarized in Table E5. Table E6 describes conditions associated with false-positive and false-negative sweat test results.
- DNA testing may be useful for confirming the diagnosis and providing genetic information for family members.
- Sputum culture and sensitivity and Gram stain (frequent bacterial infections with *Staphylococcus aureus* [both MSSA and MRSA], *Pseudomonas aeruginosa* [most common virulent respiratory pathogen], *Stenotrophomonas maltophilia,* and *Burkholderia cepacia*).
- Bronchoalveolar lavage (BAL) may be used to aid in the early diagnosis of pulmonary infection in nonexpectorating patients; however, evidence for its clinical benefit is lacking. Trials have shown that among infants diagnosed with CF, BAL-directed therapy did not result in a lower prevalence of *P. aeruginosa* infection or lower total CF-CT score when compared with standard therapy at age 5 yr.
- Low albumin level, increased 72-hr fecal fat excretion.
- Pulse oximetry or arterial blood gases: Hypoxemia.
- Pulmonary function studies: Decreased total lung capacity, forced vital capacity, pulmonary diffusing capacity.

IMAGING STUDIES

- Chest x-ray (Fig. E2): May reveal focal atelectasis, peribronchial cuffing, bronchiectasis, increased interstitial markings, hyperinflation
- High-resolution chest CT scan (Fig. E3): Bronchial wall thickening, cystic lesions, ring shadows (bronchiectasis)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Mucus clearance (i.e., using postural drainage techniques, chest percussion, pneumatic vest, acapella)
- Encouragement of regular exercise and proper nutrition (daily caloric intake of 120%-200% of healthy population)
- Psychosocial evaluation and counseling of patient and family members

ACUTE GENERAL Rx

- Primary goal of CF treatment in regard to pulmonary disease is to maintain lung function as near to normal as possible by controlling respiratory infections and clearing airways of mucus.
- Antibiotic therapy is based on the results of sputum Gram stain and culture and sensitivity. *S. aureus* infections are treated with either cefazolin 1.5 g q6h or nafcillin 2 g 4-6h. MRSA should be treated with vancomycin 45-60 mg/kg/day in 3 divided doses

TABLE E3 Diagnostic Criteria for Cystic Fibrosis (CF)

Presence of typical clinical features (respiratory, gastrointestinal, or genitourinary)

or

A history of CF in a sibling

or

A positive newborn screening test

plus

Laboratory evidence for CFTR (CF transmembrane regulator) dysfunction:

Two elevated sweat chloride concentrations obtained on separate days

or

Identification of two CF mutations

or

An abnormal nasal potential difference measurement

CFTR, Cystic fibrosis transmembrane conductance regulator.
From Kliegman, RM: *Nelson textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

TABLE E4 Approach to Diagnosis of Cystic Fibrosis in Adult Patients

Conditions Suggesting the Diagnosis of Cystic Fibrosis in Adults	Recommended Diagnostic Studies
Recurrent pancreatitis	Sweat electrolyte determination
Male infertility	Extended CFTR mutation analysis
Chronic sinusitis	Nasal potential difference
Nasal polyposis	High-resolution CT scan to identify bronchiectasis
Nontuberculous mycobacterial infection	CT scan of sinuses for polyposis
Allergic bronchopulmonary mycosis	Sputum induction or bronchoalveolar lavage to identify bacterial and fungal pathogens
Bronchiectasis	

CFTR, Cystic fibrosis transmembrane conductance regulator; *CT,* computed tomography.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

TABLE E5 Sweat Test (Quantitative Pilocarpine Iontophoresis): Indications and Conditions with High Electrolyte Levels

Indications	Conditions with High Sweat Electrolyte Levels
Siblings with CF	CF
Chronic pulmonary symptoms	Ectodermal dysplasia
Persistent cough	Glycogen storage disease, type 1
Recurrent respiratory infection	Adrenal insufficiency
Bronchitis	Familial hypoparathyroidism
Bronchiectasis	Fucosidosis
Lobar atelectasis	Pitressin-resistant diabetes insipidus
Failure to thrive (stunting of growth)	Mucopolysaccharidosis
Rectal prolapse	Familial cholestasis syndrome
Nasal polyposis	Environmental deprivation syndrome
Intestinal obstruction of newborn	Acute respiratory disorders (croup, epiglottitis, viral pneumonia)
Meconium ileus	Chronic respiratory disorders (bronchopulmonary dysplasia)
Jaundice in early infancy	α_1-Antitrypsin deficiency
Cirrhosis in childhood or adolescence	
Portal hypertension	
Adult males with aspermia or azoospermia	
Heat stroke	
Hypoproteinemia	
Hypoprothrombinemia	

CF, Cystic fibrosis.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E6 Conditions Associated with False-Positive and False-Negative Sweat Test Results

With False-Positive Results	With False-Negative Results
Eczema (atopic dermatitis)	Dilution
Ectodermal dysplasia	Malnutrition
Malnutrition/failure to thrive/deprivation	Edema
Anorexia nervosa	Insufficient sweat quantity
Congenital adrenal hyperplasia	Hyponatremia
Adrenal insufficiency	Cystic fibrosis transmembrane conductance regulator mutations with preserved sweat duct function
Glucose-6-phosphatase deficiency	
Mauriac syndrome	
Fucosidosis	
Familial hypoparathyroidism	
Hypothyroidism	
Nephrogenic diabetes insipidus	
Pseudohypoaldosteronism	
Klinefelter syndrome	
Familial cholestasis syndrome	
Autonomic dysfunction	
Prostaglandin E infusions	
Munchausen syndrome by proxy	

From Kliegman, RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

or with linezolid 600 mg q12h. *P. aeruginosa* infections can be treated with piperacillin-tazobactam 4.5 g q6h plus ciprofloxacin 750 mg PO q12h. Treatment of CF exacerbations should be aimed at least at mucoid *P. aeruginosa* and *S. aureus* (i.e., piperacillin-tazobactam and ciprofloxacin). A recent study using azithromycin maintenance in children with CF for 6 mo found less use of additional antibiotics and improvement in some aspects of pulmonary function. Additional studies will be necessary to determine if azithromycin should be used as a primary therapy or rescue treatment. Inhaled antibiotics (aztreonam or tobramycin) can also be used and can achieve high airway concentration with lower systemic side effects. Intermittent administration of inhaled tobramycin has been reported to be beneficial in CF.

- Bronchodilators for patients with airflow obstruction.
- Long-term pancreatic enzyme replacement.
- Alternate-day prednisone (2 mg/kg) possibly beneficial in children with CF (decreased hospitalization rate, improved pulmonary function). Glucocorticoids are used in selected patients during an exacerbation that has characteristics of an acute asthmatic episode (e.g., chest tightness, wheezing, acute symptomatic response to inhaled beta-adrenergic agonists). Routine use of corticosteroids not recommended in adults. Boys with CF who have received alternate-day treatment with prednisone have shown persistent growth impairment after treatment is discontinued.
- Proper nutrition and vitamin supplementation (including fat-soluble vitamins A, D, E, and K).
- The mucolytic recombinant human deoxyribonuclease (DNase [dornase alfa]) 2.5 mg qd or bid given by aerosol for patients ≥6 yr of age with viscid sputum. It lowers the viscosity of sputum. It is useful to improve mucociliary clearance by liquefying difficult-to-clear pulmonary secretions. It is, however, very expensive. It is most beneficial in patients with forced vital capacity values >40% of predicted. Its cost can be decreased by using alternate-day rhDNase therapy.
- Newer treatment modalities act by improving production, intracellular processing, and/or function of the defective CFTR protein. Ivacaftor (a CFTR potentiator) is FDA approved for oral treatment of CF in patients 2 yr and older with the G551D mutation (5% of patients with CF). It can decrease the frequency of pulmonary exacerbations and improve lung function. Cost is a significant limiting factor. A new combination drug, tezacaftor-ivacaftor, has been reported to work as well or better than ivacaftor for most of the same mutations as were approved for ivacaftor. Tezacaftor-ivacaftor is approved only for patients aged 12 yr and above. Another combination treatment, lumacaftor-ivacaftor, has been FDA-approved for patients aged 12 yr and above who are homozygous for the F508del mutation in the *CFTR* gene. Most recommendations call for

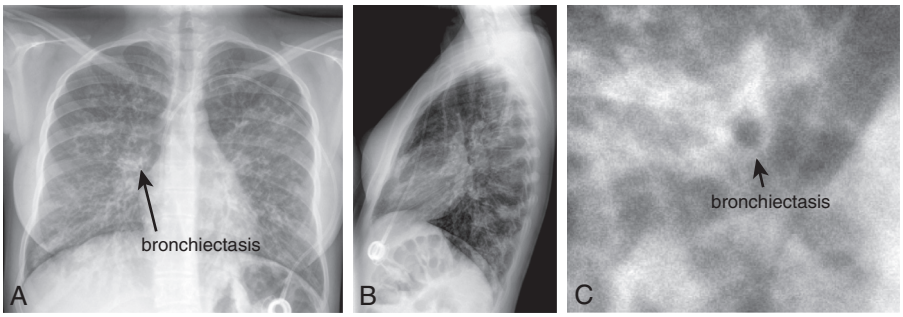

FIG. E2 Cystic fibrosis. Cystic fibrosis is aptly named. Chest x-ray findings include increased interstitial density of fibrosis and cystic changes of lung parenchyma similar to chronic obstructive pulmonary disease. Bronchiectasis (dilation of bronchi, potentially eroding into bronchial arteries and presenting with hemoptysis) may be visible on chest x-ray as large and thickened bronchioles, particularly when viewed in short axis (when bronchioles are oriented perpendicular to the frontal plane). This 15-yr-old with cystic fibrosis presented with cough and dyspnea. Does she have pneumonia? Comparison with prior x-rays showed no changes. **A,** Posterior-anterior chest x-ray. **B,** Lateral chest x-ray. **C,** Close-up of **A** showing bronchiectasis. (From Broder JS: *Diagnostic imaging for the emergency physician*, Philadelphia, 2011, Saunders.)

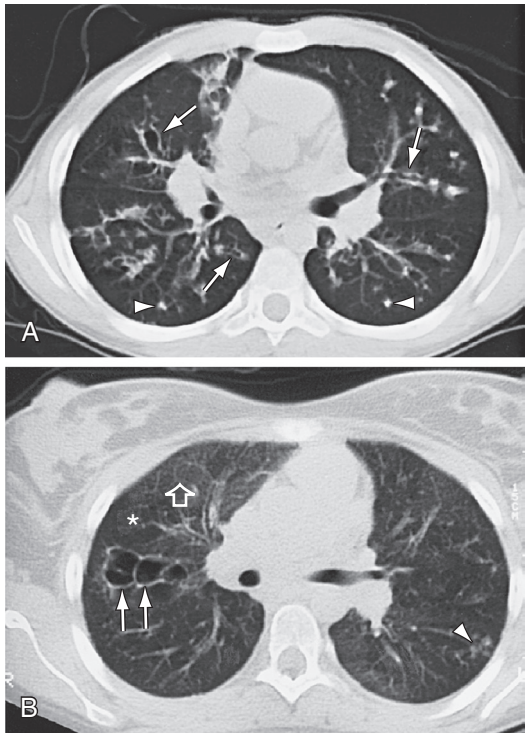

FIG. E3 CT scans of the chest in cystic fibrosis. A, A 12-yr-old boy with moderate lung disease. Airway and parenchymal changes are present throughout both lungs. Multiple areas of bronchiectasis *(arrows)* and mucous plugging *(arrowheads)* can be seen. **B,** A 19-yr-old girl has mostly normal lung with one area of saccular bronchiectasis in the right upper lobe *(arrows)* and a focal area of peripheral mucous plugging in the right lower lobe *(arrowhead).* Lung density is heterogenous, with areas of normal lung *(open arrow)* and areas of low attenuation reflecting segmental and subsegmental air trapping *(asterisk).* (From Kliegman, RM: Nelson *textbook of pediatrics,* ed 21, Philadelphia, 2020, Elsevier.)

the use of tezacaftor-ivacaftor for residual function mutations and F508del homozygotes mutations >12 yr of age. If the patient's genotype is unknown, an FDA-cleared CF mutation test should be used to detect the presence of the F508del mutation on both alleles of the *CFTR* gene. Recent phase 3 trials involving the next-generation cystic fibrosis transmembrane conductance regulator (CFTR) corrector VX-659 in triple combination with tezacaftor and ivacaftor resulted in significant improvements for patients with Phe508del-MF or Phe508del-Phe508del genotypes. Based on these results, VX-659 triple combination regimens have the potential to treat the underlying cause of disease in ~90% of patients with CF.

- Limitations of use: Efficacy and safety have not been established in patients with CF other than those homozygous for the F508del mutation.
- Treatment of impaired glucose tolerance and diabetes mellitus.

CHRONIC Rx

- Pneumococcal and influenza vaccination.
- Chronic treatment with oral antibiotics to control infection is not recommended with two exceptions (see below).
- Azithromycin is recommended for many patients due to its benefits from antiinflammatory and/or antibacterial properties. Should be started on patients ≥6 yr of age with persistent *P. aeruginosa* in airway cultures for inhibition of neutrophil migration and elastase production.
- Chronic treatment with nebulized antibiotics (aztreonam or tobramycin) can be used daily for *P. aeruginosa* colonization.

DISPOSITION

- Bronchiectasis develops early in the course of cystic fibrosis, being detectable in infants as young as 10 wk of age, and is persistent and progressive. Recent data[1] reveal that neutrophil elastase activity in BAL fluid in early life is associated with early bronchiectasis in children with cystic fibrosis.
- More than 50% of children with CF live beyond age 20 yr. During the past 2 decades, survival among patients with late-stage CF has lengthened substantially. Survival has improved at the rate of 1.8% annually during the past decade. This is believed due to increased use of NBH DNase.
- Lung transplantation is the only definitive treatment; 3-yr survival after transplantation exceeds 50%.
- Obstructive azoospermia is present in >98% of postpubertal males.
- The SERPINA Z allele is a risk factor for liver disease in CF. Patients who carry the Z allele are at a greater risk of developing severe liver disease with portal hypertension.

REFERRAL

- Lung transplantation is advised in selected patients. Indications for lung transplantation include FEV_1 <30% of predicted, rapidly progressive respiratory deterioration, increasing number of hospital admissions, massive hemoptysis, recurrent pneumothorax, arterial partial pressure of oxygen <55 mm Hg, arterial partial pressure of carbon dioxide >50 mm Hg, multidrug-resistant organisms (although most centers will deny transplant to patients with *Burkholderia* colonization), and wasting. Young female patients should be referred earlier because of overall poorer prognosis. Selected patients must undergo double lung transplant.
- For screening of family members with DNA analysis.

[1]Sly PD et al: Risk factors for bronchiectasis in children with cystic fibrosis, *N Engl J Med* 368:1963-1970, 2013.

PEARLS & CONSIDERATIONS

COMMENTS

- Clinicians should think of CF in any patient with bronchiectasis plus any of the following: Male infertility, recurrent idiopathic pancreatitis, recurrent nasal polyposis.
- Genetic testing for CF should be offered to adults with a positive family history of CF, couples currently planning a pregnancy, and couples seeking prenatal care.
- Inhalation of hypertonic saline (5 ml of 7% sodium chloride qid) has been reported to produce a sustained acceleration of mucus clearance and improved lung function.
- The prevalence of MRSA in the respiratory tract of individuals with CF has increased dramatically over the past decade and is associated with worse survival.

BASIC INFORMATION

DEFINITION

Cysticercosis is an infection caused by the tissue deposition of larval forms of the pork tapeworm *Taenia solium. T. solium* cysts, or cysticerci, may accumulate in any human tissue, including the eyes, spinal cord, skin, muscle, heart, and brain. Central nervous system (CNS) involvement is common and is known as neurocysticercosis. Humans most commonly acquire cysticercosis via fecal-oral transmission from human tapeworm carriers or via ingestion of larval cysts in infected pork or tapeworm eggs in contaminated water or soil. Larvae in the gastrointestinal tract migrate hematogenously to tissues, where they encyst, forming cysticerci.

SYNONYMS

Cysticerciasis
Taeniasis
Pork tapeworm

ICD-10CM CODES	
B69	Cysticercosis
B69.0	Cysticercosis of central nervous system
B69.1	Cysticercosis of eye
B69.81	Myositis in cysticercosis
B69.89	Cysticercosis of other sites
B69.9	Cysticercosis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- *T. solium* infection is worldwide in distribution. Tapeworm infection and cysticercosis are endemic in developing countries where pigs are raised as a food source, including developing countries of Central America, South America, and parts of Africa and Asia.
- Serologic studies from endemic areas of Latin America and Africa have demonstrated seroprevalence rates of 4% to 24% in native populations.
- Neurocysticercosis is most common in the United States in areas with large immigrant populations from countries where the disease is endemic.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- After ingestion of *T. solium* eggs or cysts, humans may remain asymptomatic for years.
- Cysticerci in muscles and skin may form subcutaneous nodules without erythema, warmth, or tenderness, mimicking lipomas or subcutaneous cysts.
- Neurocysticercosis, the presence of cysts within the brain parenchyma, is usually asymptomatic. Symptoms develop due to the inflammatory response to degeneration of cysts, which can result in focal encephalitis, vasculitis, chronic meningitis, and cranial nerve palsies.
- Seizures are the most common manifestation of neurocysticercosis, occurring in 70% to 90% of symptomatic cases. Headache and focal neurologic deficits can also occur.
- Up to 40% of patients with epilepsy in endemic areas have neurocysticercosis.
- In 10% to 20% of cases of neurocysticercosis, cysts lodge within the ventricular system and result in obstructive hydrocephalus, causing acute intracranial hypertension. Symptoms are caused by the presence of the parasite itself, ependymal inflammation, and/or fibrosis, each of which blocks the circulation of cerebrospinal fluid (CSF). Death may occur from progressive hydrocephalus, cerebral edema, or intractable seizures.
- Ocular cysticercosis occurs in less than 5% of infections and is generally asymptomatic. Inflammation in response to degenerating cysticerci may result in chorioretinitis, vasculitis, or retinal detachment, threatening vision.
- Cysticercosis cellulosae cutis presents with multiple firm, nontender subcutaneous nodules mimicking lipomas or epidermoid cysts.

ETIOLOGY

- *T. solium* has a complex two-host life cycle.
- Humans are the only definitive host and harbor the adult worm in the intestine (taeniasis). However, both humans and pigs can serve as intermediate hosts and harbor the larvae or cysticerci.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Epilepsy of unknown etiology
- Migraine
- CNS vasculitis
- Primary neoplasia of CNS
- Chronic CNS infections, including toxoplasmosis, coccidioidomycosis, tuberculosis, and cryptococcosis
- Brain abscess
- CNS involvement with sarcoidosis or systemic lupus erythematosus

WORKUP

Comprehensive clinical history: Obtain information on current and previous travel and residence, including geographic area, sanitary conditions, and consumption of undercooked pork.

LABORATORY TESTS

- Serum antibody detection by enzyme-linked immunoelectrotransfer blot (EITB) assay has a sensitivity of 98% and a specificity of 100% in patients with more than one cyst but has less predictive value in patients with a single cyst, in which up to 38% can be falsely negative. The same assay can be performed in CSF, with lower sensitivity. Antibodies detected by EITB can persist for years after successful therapy, limiting the usefulness of this assay in following patients after treatment. In endemic regions, a negative test result is useful in ruling out disease but a positive result is a marker of exposure, not necessarily symptomatic infection.
- Circulating *T. solium* antigens (B158/B60 monoclonal antibody-based sandwich ELISA, Ag-ELISA) can be detected in serum and CSF, providing a marker of viable organisms, even when CNS lesions are calcified and presumed to be inactive. This method may be particularly useful in monitoring patients after therapy. Antigen levels usually fall within 3 mo of successful treatment.
- Polymerase chain reaction (PCR) detection of *T. solium* DNA has been developed, with a reported sensitivity of 96.7%, but it is not widely available.
- Definitive diagnosis is based on the histopathologic demonstration of cysticerci in the tissue involved. Fine-needle aspiration cytology may be useful in diagnosing infection.
- Peripheral eosinophilia is usually absent.
- Stool examination for ova and proglottids of *T. solium* is insensitive and not specific for the diagnosis of cysticercosis.
- CSF examination in neurocysticercosis is usually unremarkable, but may demonstrate pleocytosis, with lymphocytic or eosinophilic predominance, low glucose, and elevated protein.

IMAGING STUDIES

- Plain radiographs of the extremities may reveal calcified cysts in patients with soft tissue or muscle involvement.
- High-resolution ultrasound may be useful in detecting subcutaneous cysts containing scoleces.
- For diagnosis of neurocysticercosis, CT and MRI are most commonly used.
- Brain CT (Fig. E1) has a sensitivity and specificity of 95% and can identify living cysticerci, which appear as hypodense lesions, as well as degenerating cysts, which appear as isodense or hyperdense lesions with surrounding edema. CT is the best method for detecting calcification associated with prior infection, which suggests inactivity.
- Brain MRI is the most accurate technique to assess the extent of infection, location, and evolutionary stage of the parasites. MRI provides detailed images of living and degenerating cysts, perilesional edema, as well as small cysts or those located in the ventricles, brainstem, and cerebellum. However, MRI has a low sensitivity for detecting calcified lesions, which are the most common neuroimaging finding in endemic populations.

TREATMENT

ACUTE GENERAL Rx

Asymptomatic cysticercosis:

- There is no evidence that administering antiparasitic therapy is beneficial.

Symptomatic neurocysticercosis:

- The goals of treatment are to control seizures and mass effect from cysticercal lesions, control intracranial hypertension, and reduce the size of active cysts.
- Treatment decisions in neurocysticercosis should be individualized. Initial measures should focus on the symptomatic management, considering antiparasitic therapy when appropriate.

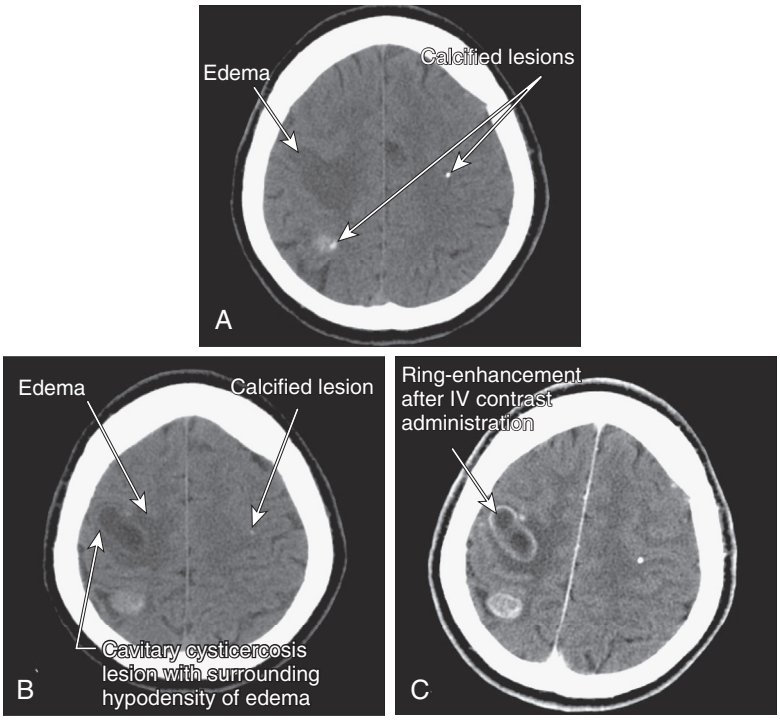

FIG. E1 Neurocysticercosis. This 40-yr-old Bolivian man presented with left-hand weakness. **A, B,** Noncontrast head computed tomography (CT) scan, brain windows. **C,** CT scan with contrast moments later; compare this with **(B)**. A slice through the same level of the brain before contrast administration. Hypodense lesions are present, with surrounding hypodensity *(dark gray)* representing edema. Scattered calcifications also are seen, a common feature of old neurocysticercosis lesions. Administration of intravenous contrast leads to ring enhancement, a feature of many infectious and inflammatory conditions, including neurocysticercosis, brain abscess, and toxoplasmosis. (From Broder JS: *Diagnostic imaging for the emergency physician*, Philadelphia, 2011, Saunders.)

- Patients with active lesions, with evidence of surrounding edema and/or inflammation, generally warrant treatment with antiparasitics, corticosteroids, and anticonvulsants.
  1 Patients who have seizures or are considered at risk for recurrent seizures based on imaging should be treated with anticonvulsants.
  2 Corticosteroids may decrease inflammation and edema and should be given whenever antiparasitic therapy is given.
  3 Antiparasitic therapy is indicated in the treatment of symptomatic patients with multiple viable brain parenchymal cysticerci. Despite treatment, only 30% to 50% of lesions resolve within 6 mo.
  4 Calcified cysticerci are generally inactive and do not warrant antiparasitic treatment.
  5 Antiparasitic therapy is often unnecessary in patients with single cysts, which are usually self-limited and resolve spontaneously within 6 mo.

Antiparasitic therapy:

- Patients with one or two viable parenchymal or subarachnoid cysts should be treated with albendazole 15 mg/kg/day PO divided twice daily for 10 to 14 days.
- Patients with three or more viable cysticerci should receive combination therapy with praziquantel (50 mg/kg per day) and albendazole (15 mg/kg per day) for 14 days.
- Praziquantel, while active against *Taenia solium,* is no longer preferred treatment for cysticercosis.
- Patients should receive prednisolone (2 mg/kg/day) or dexamethasone (0.15 mg/kg/day) orally before initiation of antiparasitic therapy.
- Antiparasitics should be used cautiously in patients with massive cysticercal infection of the brain parenchyma (≥50 cysts) or cysticercal encephalitis. These patients should be managed initially with corticosteroids, and perhaps mannitol, to control intracranial hypertension. Once the inflammation and edema have resolved by MRI, antiparasitics can be administered.

Surgical therapy:

- Surgery may be indicated in patients with obstructive hydrocephalus or giant cysts with associated intracranial hypertension.
- Minimally invasive neurosurgery (neuroendoscopy) for cyst removal and ventricular shunt formation has greatly improved the management of intraventricular neurocysticercosis.
- Extraparenchymal neurocysticercosis, including ocular, subarachnoid, and intraventricular disease, carries a poor prognosis and requires a more aggressive approach. When feasible, complete surgical excision of lesions remains the definitive therapy.

CHRONIC Rx

- Prolonged antiparasitic therapy does not improve outcomes in neurocysticercosis and may delay calcification of lesions. Antiepileptic medications should be continued for 2 yr or 6 to 12 mo after CT/MRI resolution of viable cysts, before tapering. In some cases, antiepileptic therapy needs to be continued indefinitely.
- Rare patients with neurocysticercosis develop chronic or recurrent perilesional inflammation, requiring long-term, high-dose steroid therapy. Methotrexate has been reported to be of use as a steroid-sparing agent in this setting.

DISPOSITION

- In seizure-free, stable neurocysticercosis, outpatient management is appropriate.
- Patients with seizures should be restricted from driving.

REFERRAL

- Infectious diseases consultation
- Neurology consultation in patients with seizures
- Neurosurgical consultation if extraparenchymal neurocysticercosis or obstructive hydrocephalus is present

PREVENTION

- Eradication of taeniasis/cysticercosis is possible with implementation of meat inspection, improvement of pig husbandry, and improvement of socioeconomic conditions in endemic areas.
- A porcine vaccine against *T. solium* has been developed and successfully implemented in Peru, Mexico, and Australia.
- There is currently no human vaccine to prevent tapeworm infection or cysticercosis.

PATIENT & FAMILY EDUCATION

- Pork should be inspected for the presence of cysticerci, which are visible in raw meat.
- Pork must be well cooked.
- Proper disposal of human excreta and handwashing are of utmost importance to break the transmission cycle in households.

Cytomegalovirus Infection

BASIC INFORMATION

DEFINITION

Infection with cytomegalovirus (CMV), a herpes virus, is common in the general population, with multiple mechanisms for transmission, often during childhood and adolescence. CMV is associated with pregnancy and can be a congenital disease. CMV is also associated with immunocompromised states and may be life-threatening.

SYNONYMS

CMV
Heterophil-negative mononucleosis
Cytomegalic inclusion disease virus

ICD-10CM CODES

B25.9	Cytomegaloviral disease, unspecified
P35.1	Congenital cytomegalovirus infection
Z20.820	Contact with and (suspected) exposure to varicella

EPIDEMIOLOGY & DEMOGRAPHICS

- Seroprevalence is widespread: 60% to 90% antibody positivity in adults.
- Increased infection develops perinatally, in day care exposure, and then during reproductive age, related to sexual activity.

ROUTES OF TRANSMISSION

- Blood transfusions
- Sexually transmitted diseases (STDs) via uterus, cervix, and semen
- Perinatally via breast milk
- Transplant of organs—bone marrow, kidneys, liver, heart, or lung
- Saliva

PHYSICAL FINDINGS & CLINICAL PRESENTATION

CHILDREN: Congenital—25% of infected children with symptoms if congenital:
- Petechial rash
- Jaundice and/or hepatosplenomegaly
- Lethargy
- Respiratory distress
- CNS involvement, seizures

Postnatal acquisition:
- CMV mononucleosis
- Pharyngitis, croup, bronchitis, pneumonia

HEALTHY ADULTS: Common:
- May be asymptomatic
- CMV mononucleosis similar to EBV mononucleosis
- Fever—lasting 9 to 30 days—mean of 19 days

Less common:
- Exudative pharyngitis
- Lymphadenopathy, hepatitis, splenomegaly
- Interstitial pneumonia (rare)
- Nonspecific rash
- Thrombocytopenia/hemolytic anemia

Rare:
- Guillain-Barré syndrome
- Meningoencephalitis
- Myocarditis

IMMUNOSUPPRESSED PATIENTS:
- Febrile mononucleosis
- GI ulcerations, hepatitis, pneumonitis, retinitis, encephalopathy, meningoencephalopathy
- HIV associated—dementia, demyelination, retinitis, acalculous cholecystitis, adrenalitis, diarrhea, enterocolitis, esophagitis
- Diabetes associated with pancreatitis
- Adrenalitis associated with HIV

ETIOLOGY

- Human herpesvirus (HHV)-5
- CMV infection can remain latent and reactivate with immunosuppression

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Congenital:
- Acute viral, bacterial, parasitic infections including other congenitally transmitted agents (toxoplasmosis, rubella, syphilis, pertussis, croup, bronchitis)

Acquired:
- EBV mononucleosis
- Viral hepatitis—A, B, C
- Cryptosporidiosis
- Toxoplasmosis
- *Mycobacterium avium* infections
- Human herpesvirus 6
- Acute HIV infection

WORKUP

- Laboratory confirmation combined with clinical findings often with leukopenia, thrombocytopenia, lymphocytosis. Diagnostic modalities include serologic assays, PCR, detection of CMV PP25 antigen in leukocytes, isolation of virus from body fluids and urine, and cytopathic demonstration of "owl eye" intracellular inclusions.
- Serology:
  1. Detection of CMV-IgM antibodies suggests recent infection. CMV-IgG antibodies usually appear 2 to 3 wk after infection.
  2. Molecular assays (PCR viral loads): On plasma.
  3. CMV antigenemia assays: Detects antibodies to the pp65 protein of the virus in peripheral blood leukocytes. These tests and the PCR tests are used in immunocompromised, AIDS, and transplant patients.
- Cultures: Using human fibroblast cultures of blood, CSF, urine, BAL, and biopsy specimens but can take 1 to 6 wk.
- Funduscopic—necrotic patches with white granular component of retina.
- Biopsy—"owl eye" inclusion bodies on tissue sample.
- HIV.

IMAGING STUDIES

- Chest radiograph—if pneumonitis suspected, consider bronchoscopy
- Endoscopy—if GI involvement
- CT scan/MRI—if CNS involvement

TREATMENT

NONPHARMACOLOGIC THERAPY

- Strict hand washing and standard precautions limit CMV transmission in health care facilities.
- Antiretroviral therapy (ART) in patients with CD4 count $<50/mm^3$ for the goal of CD4 $>100/mm^3$ for a 3- to 6-mo period.

ACUTE GENERAL Rx

Antiviral therapy with intravenous ganciclovir or oral valganciclovir is appropriate in immunocompromised patients. It can also be used in immunocompetent patients with severe disease.

For compromised hosts with CMV retinitis or pneumonitis:
- Ganciclovir 5 mg/kg q12h IV × 14 to 21 days, then valganciclovir: 900 mg PO q24h or alternative regimen
- Ganciclovir intraocular implant plus valganciclovir 900 mg PO q24h or alternative regimen
- Foscarnet 90 mg/kg q12h × 14 to 21 days, then 90 mg to 120 mg/kg IV q24h or alternative regimen
- Cidofovir 5 mg/kg IV q day × 14 days, then 5 mg/kg IV q 2 wk
- Fomivirsen-salvage therapy for CMV retinitis 300 μg injected into vitreous

DISPOSITION

- CMV infection in patients who are immunocompromised (especially those with AIDS, bone marrow and solid organ transplant recipients, and disorders of cell-mediated immune function) will need expert, long-term follow-up by an infectious disease specialist or immunologist familiar with the care of such patients.
- CMV mononucleosis, hepatitis, pharyngitis, etc. in immunologically normal hosts are usually self-limiting infections requiring no special follow-up plans.

REFERRAL

- To an ophthalmologist if CMV retinitis is present
- To an infectious disease specialist or AIDS specialist for patients who are HIV-positive with CMV disease
- To a cellular immunologist or transplant specialist in the case of CMV infection in a transplant recipient
- To a pediatric infectious disease specialist for congenital CMV infection

PEARLS & CONSIDERATIONS

CMV is ubiquitous in the environment and is asymptomatically shed by latently infected persons with CMV infection, making it difficult to protect patients who are immunocompromised from acquiring this infection.

BASIC INFORMATION

DEFINITION

Venous thromboembolism is any thromboembolic event occurring within the venous system. Deep vein thrombosis (DVT) is the development of thrombi in the deep veins of the extremities or pelvis.

SYNONYMS

DVT
Venous thromboembolism (VTE) (VTE includes DVT and pulmonary embolism [PE])
Deep venous thrombosis
VTE

ICD-10CM CODES

I82.401	Acute embolism and thrombosis of unspecified deep veins of right lower extremity
I82.402	Acute embolism and thrombosis of unspecified deep veins of left lower extremity
I82.403	Acute embolism and thrombosis of unspecified deep veins of lower extremity, bilateral
I82.621	Acute embolism and thrombosis of deep veins of right upper extremity
I82.622	Acute embolism and thrombosis of deep veins of left upper extremity
I82.623	Acute embolism and thrombosis of deep veins of upper extremity, bilateral

EPIDEMIOLOGY & DEMOGRAPHICS

- Annual incidence of VTE is 0.1% to 0.27%, affecting up to 5% of the population during their lifetimes.
- The risk of recurrent thromboembolism is higher among men than women.
- In the U.S., there are approximately 900,000 DVT events annually. About 5% to 15% of persons with untreated DVT die from pulmonary embolism.
- Venous thromboembolism occurs in nearly 2 cases per 1000 pregnancies and is a leading cause of maternal mortality and morbidity.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pain and swelling of the affected extremity
- In lower extremity DVT: Leg pain on dorsiflexion of the foot (***Homan* sign**)
- Physical examination may be unremarkable in early DVT

ETIOLOGY

The etiology is often multifactorial (prolonged stasis, coagulation abnormalities, vessel wall trauma (Fig. 1). The following are risk factors for DVT:

- Prolonged immobilization (>3 days)
- Postoperative state
- Trauma to pelvis and lower extremities for lower extremity DVT; central line placement for upper extremity DVT
- Birth control pills, high-dose estrogen therapy; conjugated equine estrogen but not esterified estrogen is associated with increased risk of DVT; estrogen plus progestin is associated with doubling the risk of venous thrombosis. The use of bevacizumab is also significantly associated with an increased risk of developing DVT in cancer patients receiving this drug
- Visceral cancer (lung, pancreas, alimentary tract, genitourinary tract)
- Occult cancer is detected in 1 in 20 patients within a year of receiving a diagnosis of unprovoked VTE
- Age >60 yr
- History of thromboembolic disease
- Hematologic disorders (e.g., factor V Leiden mutation [FVL], antithrombin III deficiency, protein C deficiency, protein S deficiency, heparin cofactor II deficiency, sticky platelet syndrome, G20210A prothrombin mutation, lupus anticoagulant, dysfibrinogenemias, anticardiolipin antibody, hyperhomocysteinemia, concurrent homocystinuria, high levels of factors VIII, XI, and single nucleotide polymorphisms [SNPs] such as CYP4V2). A classification of hypercoagulable states is described in Table 1
- Pregnancy and early puerperium
- Obesity (BMI >30)
- Congestive heart failure
- Surgery, fracture, or injury involving lower leg or pelvis
- Plaster cast immobilization
- Surgery requiring >30 min of anesthesia
- Gynecologic surgery (particularly gynecologic cancer surgery)
- Recent travel (within 2 wk, lasting ≥2 hr). Every 2 hr spent traveling increases VTE risk by 18%
- Smoking and abdominal obesity
- Central venous catheter or pacemaker insertion
- Superficial vein thrombosis (10% risk of DVT within 3 mo), varicose veins
- Collagen vascular disease
- Nephrotic syndrome
- Myeloproliferative disorders
- Testosterone therapy
- Long-term exposure to particulate air pollution is also associated with altered coagulation function and DVT risk
- Varicose veins

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Postphlebitic syndrome
- Superficial thrombophlebitis
- Ruptured Baker cyst
- Cellulitis, lymphangitis, Achilles tendinitis
- Hematoma
- Muscle or soft tissue injury, stress fracture
- Varicose veins, lymphedema
- Arterial insufficiency
- Abscess
- Claudication
- Venous stasis

WORKUP

- The clinical diagnosis of DVT is inaccurate. Pain, tenderness, swelling, or color changes are not specific for DVT.
- Clinical prediction rules can be used to establish pretest probability of DVT. The Wells prediction rules for DVT and for pulmonary embolism are described in Table 2. These rules perform better in younger patients without a history of DVT and in those without comorbidities. In younger patients without

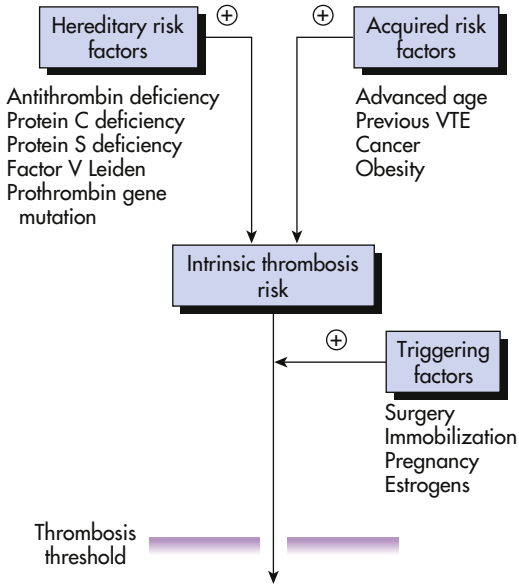

FIG. 1 Thrombosis threshold. Hereditary and acquired risk factors combine to create an intrinsic risk for thrombosis in each individual. This risk is increased by extrinsic triggering factors. If the intrinsic and extrinsic forces exceed a critical threshold at which thrombin generation overwhelms protective mechanisms, thrombosis occurs. *VTE,* Venous thromboembolism. (From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.)

TABLE 1 Classification of Hypercoagulable States

Hereditary	Mixed	Acquired
Loss of Function		
Antithrombin deficiency	Hyperhomocysteinemia	Advanced age
Protein C deficiency		Previous venous thromboembolism
Protein S deficiency		Surgery
Gain of Function		Immobilization
Factor V Leiden		Obesity
Prothrombin gene mutation		Cancer
Elevated factor VIII, IX, or XI levels		Pregnancy, puerperium
		Drug-induced: L-asparaginase, hormonal therapy

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine,* ed 11, Philadelphia, 2019, Elsevier.

TABLE 2 Wells Scoring Scheme for Pre-Test Probability of Deep Vein Thrombosis*

Clinical Feature	Points
Risk Factors	
Active cancer	1
Paralysis, paresis, or recent plaster immobilization of the lower extremities	1
Recently bedridden >3 days or major surgery, within 4 wk	1
Signs	
Localized tenderness along the distribution of the deep venous system	1
Entire leg swollen	1
Asymmetric calf swelling (>3 cm difference, 10 cm below tibial tuberosity)	1
Asymmetric pitting edema	1
Collateral superficial veins (nonvaricose)	1
Alternative Diagnosis	
Alternative diagnosis as likely or more likely than deep venous thrombosis	–2

*Interpretation of score: High probability if 3 points or more, moderate probability if 1 or 2 points, and low probability if 0 points or less.

From Wells PS, et al.: Value of assessment of pretest probability of deep-vein thrombosis in clinical management. *Lancet* 350:1795–1798, 1997. In McGee S: *Evidence-based physical diagnosis*, ed 4, Philadelphia, 2018, Elsevier.

associated comorbidities and a low pretest probability using Wells criteria and a negative high-sensitivity D-dimer test, the diagnosis of DVT can be reasonably excluded.

- Compression ultrasonography (CUS; Fig. E2) is preferred as the initial study to diagnose DVT in patients with intermediate to high pretest probability. An initial negative test limited to the proximal leg should be repeated after 5 days (if the clinical suspicion of DVT persists) to exclude DVT that is propagating proximally from the calf. Comprehensive ultrasonography (whole-leg CUS) is a more extensive test that examines the deep veins from the inguinal ligament to the level of the malleolus. Literature reports indicate that it may be safe to withhold anticoagulation after negative results on comprehensive duplex ultrasonography in nonpregnant patients with a suspected first episode of symptomatic DVT of the leg.

LABORATORY TESTS

- Laboratory tests are not specific for DVT.
- Baseline prothrombin time (INR), partial thromboplastin time, and platelet count should be obtained on all patients.
- D-dimer testing is sensitive but not specific for DVT. A negative result (D-dimer <0.5 mcg/ml) can exclude the diagnosis in a patient with low probability of DVT, but a positive result (≥0.5 mcg/ml) mandates additional testing with venous ultrasonography.
- Laboratory evaluation of young patients with DVT, patients with recurrent thrombosis without obvious causes, and those with a family history of thrombosis should include protein S (both total and free PS), protein C, fibrinogen, antithrombin III level, lupus anticoagulant, anticardiolipin antibodies, anti-b2 glycoprotein1, factor V Leiden, factor VIII, factor IX, and fasting plasma homocysteine levels. It is important to remember that the lupus anticoagulant assay and antithrombin, protein C, protein S, and dysfibrinogenemia testing cannot be properly interpreted if a patient is already on warfarin, whereas anticardiolipin antibody test, prothrombin G20210A factor VII:C, factor V Leiden, and PT polymorphism can be performed when a patient is on warfarin.

IMAGING STUDIES

- Compression ultrasonography (CUS) is generally preferred as the initial study because it is noninvasive and can be repeated serially (useful to monitor suspected acute DVT); it offers good sensitivity for detecting proximal vein thrombosis (in the popliteal or femoral vein). Its disadvantages are poor visualization of deep iliac and pelvic veins and poor sensitivity in isolated or nonocclusive calf vein thrombi. Whole-leg compression ultrasound can generally exclude proximal and distal DVT in a single evaluation. Withholding anticoagulation following a single negative whole-leg CUS is associated with a relatively low risk of venous thromboembolism (3.5% of inpatients will develop DVT) during a 3-mo follow-up.
- Contrast venography is the gold standard for evaluation of DVT of the lower extremity. It is, however, invasive and painful and rarely used in clinical practice. Additional disadvantages are the increased risk of phlebitis, new thrombosis, renal failure, and hypersensitivity reaction to contrast media; it also gives poor visualization of the deep femoral vein in the thigh and the internal iliac vein and its tributaries.
- Magnetic resonance direct thrombus imaging (MRDTI) is an accurate noninvasive test for diagnosis of DVT. It is particularly useful in suspected DVT patients with leg casts, which prevent CUS, and in pregnant patients with positive D-dimer and negative CUS. Current limitations are its cost and lack of widespread availability.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Gradual resumption of normal activity. Immobility promotes stasis and propagation of DVT. Patients should get up and walk as tolerated. The theoretical risk that ambulation may dislodge thrombi in the legs, precipitating PE, is unfounded.
- Patient education on anticoagulant therapy and associated risks.

ACUTE GENERAL Rx

- Direct oral anticoagulants (DOACs) apixaban or rivaroxaban are prepared as monotherapy for initial treatment of DVT. These new anticoagulants (Table 3) are noninferior to warfarin, do not require periodic lab monitoring, and have a relatively low bleeding risk. They are preferred agents for extended treatment of venous thromboembolism if cost is not a significant issue.

TABLE 3 Comparison of Dabigatran, Rivaroxaban, Apixaban, and Edoxaban

	Dabigatran	Rivaroxaban	Apixaban	Edoxaban
Target	Thrombin (IIa)	Factor Xa	Factor Xa	Factor Xa
Active drug	No	Yes	Yes	Yes
Onset time (hr)	0.5-2	2-4	3-4	1-3
Half-life (hr)	12-17	5-13	~12	9-11
Renal excretion (%)	80	33	27	50

Hoffman R, et al.: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2017, Elsevier.

BOX 1 Contraindications to Outpatient Treatment of Venous Thromboembolism[a]

- Active or high risk of bleeding
- Recent surgery (within 7 days)
- Cardiopulmonary instability
- Severe symptomatic venous obstruction
- High risk of pulmonary embolism
- Thrombocytopenia (platelets <50,000/μL)
- Other medical or surgical condition requiring inpatient management
- Medical noncompliance
- Geographic or telephone inaccessibility
- Poor hepatic function (international normalized ratio ≥1.5)
- Unstable renal function (e.g., rising serum creatinine)
- Poor home health care support environment

[a]Not an all-inclusive list.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

- When apixaban or rivaroxaban are not available or contraindicated, initial treatment of DVT requires therapeutic doses of heparin (low-molecular-weight heparin [LMWH] or unfractionated). LMWH is preferred due to ease of administration, less hemorrhage, and significantly fewer deaths. Unfractionated heparin is preferred in patients with renal insufficiency because LMWH is predominantly excreted in the urine.
- LMWH is generally administered for 5 to 7 days. Recommended dose of enoxaparin is 1 mg/kg q12h SC. Once-daily fondaparinux, a synthetic analogue of heparin, is also as effective and safe as twice-daily enoxaparin in the initial treatment of patients with symptomatic DVT. Once systemic anticoagulation is initiated, vitamin K antagonist warfarin is initiated. Warfarin is titrated to maintain an INR between 2 and 3. After ≥5 days, heparin is stopped and warfarin is continued as monotherapy. Long-term LMWH may be preferable to warfarin in patients with cancer or those whose INR is difficult to control.
- Outpatient treatment of DVT is appropriate for patients without thrombophilic conditions or substantial comorbidity. Exclusions from outpatient treatment of DVT (Box 1)include patients with potential high complication risk (e.g., active or high risk of bleeding, hemoglobin <7, platelet count <50,000, guaiac-positive stool, recent cerebrovascular accident or noncutaneous surgery, noncompliance).
- Compression stockings are effective in reducing the incidence of postthrombotic syndrome and should be used starting within 1 mo of proximal DVT and continued for at least 1 yr after diagnosis.
- Insertion of an inferior vena cava filter to prevent pulmonary embolism is recommended in patients with contraindications to anticoagulation (e.g., hemorrhagic stroke, active internal bleeding, pregnancy), HIT in a patient with an active VTE/PE, recurrent PE despite adequate anticoagulant therapy, emergent surgery in patient with DVT, presence of free-floating iliofemoral thrombus, lower IVC thrombosis (incipient embolization), and chronic pulmonary (thromboembolic) hypertension with limited pulmonary reserve. Table 4 summarizes indications for IVC filter placement.
- Thrombolytic therapy (streptokinase) can be used in rare cases (unless contraindicated) in patients with extensive iliofemoral venous thrombosis and a low risk of bleeding. There are concerns about hemorrhagic complications related to the large doses of thrombolytics required in systemic thrombolysis for DVT (2% to 10% risk of major hemorrhagic complications).
- Other treatment modalities for DVT include surgical thrombectomy and catheter-directed thrombolysis (CDT). Thromboreduction by surgical thrombectomy is effective but invasive and expensive. CDT is also invasive, carries a bleeding risk, and will generally require ICU admission.

CHRONIC Rx

- The optimal duration of anticoagulant therapy varies with the cause of DVT and the patient's risk factors. The risk of recurrence is low if VTE is provoked by surgery, intermediate if provoked by a nonsurgical risk factor, and high if unprovoked. These risks should determine whether patients with VTE should undergo short-term vs. indefinite treatment.
- Therapy for 3 mo is generally satisfactory in patients with reversible risk factors (low-risk group). A high D-dimer level measured after 3 mo of anticoagulation in patients with unprovoked DVT should favor a longer duration of therapy. The American College of Chest Physicians Guidelines suggests that patients with first unprovoked VTE receive indefinite anticoagulation unless their bleeding risk is high.
- The risk of recurrence in patients with a first unprovoked VTE who have negative D-dimer results is not low enough to justify stopping anticoagulant therapy in men but may be low enough in some cases to justify stopping therapy in women who were taking estrogen at the time of initial VTE.[1]
- Anticoagulation for 6 mo is recommended for patients with idiopathic venous thrombosis or medical risk factors for DVT (intermediate-risk group). About 20% of patients with unprovoked venous thromboembolism have a recurrence within 2 yr after the withdrawal of oral anticoagulant therapy. Use of daily low-dose aspirin after discontinuation of anticoagulant treatment may provide a modest reduction in DVT risk.
- Indefinite anticoagulation is necessary in patients with DVT associated with active cancer; long-term anticoagulation is also indicated in patients with inherited thrombophilia (e.g., deficiency of antithrombin III, protein C or S antibody), high factor VIII levels, antiphospholipid antibody, and those with recurrent episodes of idiopathic DVT (high-risk group). Long-term anticoagulation should also be considered in the presence of comorbidities such as paroxysmal nocturnal hemoglobinuria (PNH), SLE (especially with nephrotic syndrome), some myeloproliferative disorders, IBD, and Cushing syndrome.
- Measurement of D-dimer after withdrawal of oral anticoagulation may be useful to estimate the risk of recurrence in selected patients. In patients with a first unprovoked DVT, positive D-dimer test results after cessation of anticoagulation predict recurrence, regardless of test timing or patient's age. Patients with a first spontaneous DVT and a D-dimer level <250 mg/ml after withdrawal of oral anticoagulation have a low risk of DVT recurrence. Risk is lower in women than in men. In patients who have completed at least 3 mo of anticoagulation for a first episode of unprovoked DVT and after approximately 2 yr of follow-up, a negative D-dimer result is associated with a 3.5% annual risk of recurrent disease, whereas a positive D-dimer result is associated with an 8.9% annual

[1]Kearon C, et al.: D-Dimer testing to select patients with a first unprovoked venous thromboembolism who can stop anticoagulant therapy: a cohort study. *Ann Intern Med* 162:27–34, 2015.

risk for recurrence. Hence, elevated D-dimer levels would be an indication for prolonged therapy (for 1 or 2 more yr at a minimum).
- The presence of residual thrombosis on ultrasonography when anticoagulant therapy is discontinued is also associated with an increased risk for subsequent recurrent DVT; a recent trial showed that tailoring the duration of anticoagulation on the basis of the persistence of residual thrombi on ultrasonography may reduce the rate of recurrent DVT. Additional trials are needed before this approach can be adapted for all patients.
- Patients with DVT and pulmonary embolism are at high risk of recurrence whenever anticoagulation is discontinued; therefore, many experts recommend prolonged anticoagulation in this population group, especially if other risk factors for recurrence are present.

PEARLS & CONSIDERATIONS

COMMENTS

- The prevalence of occult cancer is low among patients with a first unprovoked venous embolism. Routine screening with CT of the abdomen and pelvis does not provide a clinically significant benefit.[2]
- When using heparin, there is a risk of heparin-induced thrombocytopenia (HIT) (with unfractionated more so than with LMWH). Platelet count should be obtained initially and repeated every 3 days while on heparin.
- Therapeutic options for cancer-associated venous thromboembolism are summarized in Box 2.
- ***ISOLATED DEEP VEIN THROMBOSIS OF THE CALF:*** The American College of Chest Physicians Guidelines suggest (1) anticoagulation in patients with severe symptoms or risk factors for proximal extension, and (2) repeat sonogram in 2 wk in lower risk patients and anticoagulation only in those patients whose DVTs extend proximally.
- ***PROPHYLAXIS OF DVT:*** Recommended in all patients at risk (e.g., low-molecular-weight heparin [enoxaparin 30 mg SC bid or fondaparinux 2.5 mg SC daily] after major trauma, postsurgery of hip and knee; enoxaparin 40 mg SC qd post–abdominal surgery in patients with moderate to high DVT risk; gradient elastic stockings alone or in combination with intermittent pneumatic compression [IPC] boots following neurosurgery). Graduated compression stockings (GCSs) are effective for preventing air-travel-related DVT and in reducing the risk of DVT in patients hospitalized for conditions other than stroke. The type of GCSs is also important because proximal DVT occurs more often in patients with stroke who wear below-knee stockings than in those who wear high-length stockings. The new oral anticoagulants (rivaroxaban, apixaban, etc.) are effective for thromboprophylaxis after THR and TKR. However, their clinical benefits over LMWH are marginal. Betrixaban is the first FDA-approved once-daily oral direct factor Xa inhibitor for prophylaxis of VTE in adults hospitalized for an acute medical illness with risk factors for VTE and moderately or severely restricted mobility. Apixaban appears to be as effective as LMWH for thromboprophylaxis in cancer patients but poses similar risk of bleeding and should be used with caution in patients with GI malignancies, thrombocytopenia, or renal impairment. Common regimens for venous thromboembolism prevention are summarized in Table 5. Box 3 describes traditional absolute and relative contraindications to pharmacologic

[2]Carrier M, et al.: Screening for occult cancer in unprovoked venous thromboembolism, *N Engl J Med* 373:697–704, 2015.

TABLE 4 Indications for Inferior Vena Cava Filter Placement

	Indications for IVC Filter Placement	Examples
1.	DVT and contraindication to anticoagulation (A)	Hemorrhage while on anticoagulation
2.	DVT and failure of anticoagulation (A)	Recurrent DVT or PE despite anticoagulation, inability to achieve or maintain adequate anticoagulation
3.	DVT and low cardiopulmonary reserve or high mortality risk from possible PE (R)	Severe pulmonary hypertension, right heart failure, known large right-to-left shunt
4.	Populations with very high risk for PE (R)	Some postbariatric, orthopedic, or neurosurgical patients or multitrauma patients. Patients with expected prolonged immobilization
5.	High risk for life-threatening PE (R)	Large, unstable (free-floating) IVC clot
6.	DVT and high fall risk (R)	
7.	Prophylaxis during catheter-directed thrombolysis of DVT (R)	

There are two absolute indications for IVC filter placement: First, if the patient is at risk for PE (i.e., DVT) but for whatever reason he/she is not a candidate for systemic anticoagulation (i.e., hemorrhage); and second, if the patient developed a PE, new DVT, or an extension of DVT while on proper anticoagulation. There are a number of relative indications for filter placement. They are presented in rows 3 through 7. In every case the decision to place a filter compels careful consideration of the risks and benefits and may require multidisciplinary input.

(A), Absolute; *DVT,* deep vein thrombosis; *IVC*, inferior vena cava; *PE*, pulmonary embolism; *(R),* relative.

BOX 2 Therapeutic Options for Cancer-Associated Venous Thromboembolism (VTE)

Acute VTE Treatment Options
- Unfractionated heparin: 80 units/kg intravenous bolus followed by 18 units/kg/hr infusion adjusted to aPTT ratio
- Dalteparin, 200 units/kg subcutaneously every 24 hr
- Enoxaparin, 1 mg/kg subcutaneously every 12 hr
- Tinzaparin, 175 units/kg subcutaneously every 24 hr
- Fondaparinux, 5-10 mg subcutaneously every 24 hr (5 mg for weight <50 kg, 7.5 mg for weight 50-100 kg, and 10 mg for weight >100 kg)
- Initial rivaroxaban dose 15 mg twice daily; switch to 20 mg once daily after 3 wk
- Dabigatran 150 mg bid after 5 days of parenteral agent
- Apixaban 10 mg bid × 7 days followed by 5 mg bid[a]
- Edoxaban 60 mg once daily after 5 days of parenteral agent
- Vena caval filter

Chronic VTE Treatment Options
- Dalteparin, 200 units/kg subcutaneously every 24 hr for 1 mo then 150 units/kg subcutaneously every 24 hr
- Enoxaparin, 1 mg/kg every 12 hr or 1.5 mg/kg subcutaneously every 24 hr
- Tinzaparin, 175 units/kg subcutaneously every 24 hr
- Vitamin K antagonists (e.g., warfarin) adjusted for an INR of 2-3
- Rivaroxaban 20 mg once daily; consider 10 mg once daily if appropriate
- Dabigatran 150 bid after 5 days of parenteral agent
- Apixaban 10 mg bid initial × 7 days followed by 5 mg bid[a]
- Edoxaban 60 mg once daily after 5 days of parenteral agent
- Vena cava filter

Rivaroxaban should be used with caution in patients with cancer, given the limited information on this medication in patients with cancer.

[a]No data currently available for use in the cancer population.

aPTT, Activated partial thromboplastin time; *bid,* twice daily; *INR,* international normalized ratio.

From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

and mechanical venous thromboembolism prophylaxis.

- ***RECURRENT THROMBOEMBOLISM:*** The risk of recurrent venous thromboembolism in heterozygous carriers of factor V Leiden and a first spontaneous venous thromboembolism is similar to that of noncarriers of factor V Leiden; therefore, heterozygous patients should receive secondary thromboprophylaxis for a similar length of time as patients without factor V Leiden. Management of recurrent venous thromboembolism in patients with cancer is summarized in Table 6.
- ***POSTTHROMBOTIC SYNDROME:*** Approximately 20% to 50% of patients with DVT develop postthrombotic syndrome characterized by leg edema, pain, venous ectasia, skin induration, and ulceration. Patients with extensive DVT and those with more severe postthrombotic manifestations 1 mo after DVT have poorer long-term outcomes. Recent trials have shown that compression stockings after DVT do not prevent postthrombotic syndrome.
- Exercise following DVT is reasonable because it improves flexibility of the affected leg and does not increase symptoms in patients with postthrombotic syndrome.
- ***UPPER EXTREMITY DVT:*** It is less common than lower extremity DVT and is seen more frequently in patients requiring central venous catheters or wires. It confers risk for mortality, recurrent thromboembolic events, and postthrombotic syndrome similar to that of lower extremity DVT. It is classified as primary upper extremity DVT ***(Paget-Schroetter syndrome)***, defined as a thrombus in the axillary and subclavian veins in absence of identifiable thrombosis risk factors. It accounts for 20% of upper extremity DVT cases and may be due to an underlying anatomic abnormality at the thoracic outlet in combination with local hypercoagulability due to venous stretching or perivascular fibrosis from recurrent venous compression. Secondary upper extremity DVT is defined as any DVT related to a predisposing factor (e.g., insertion of central venous catheter, wires, or other devices, malignancy). In patients with secondary upper extremity DVT removal of the catheter is not routinely recommended but is warranted if there is a catheter malfunction or infection, if anticoagulation therapy is contraindicated or has failed, or if the catheter is no longer needed. Anticoagulation therapy in upper extremity DVT consists of use of vitamin K antagonists, except in patients with cancer, for whom LMWH is preferred. Optimal duration of anticoagulation treatment in upper extremity DVT is 3 to 6 mo (including in those in whom a central catheter has been removed).
- ***DVT THERAPY IN PREGNANCY:*** Vitamin K antagonists such as warfarin are

TABLE 5 Common Regimens for Venous Thromboembolism Prevention

Condition	Prophylaxis
Hospitalization with medical illness	Unfractionated heparin 5000 units SC bid or tid *or* Enoxaparin 40 mg SC qd *or* Dalteparin 2500 units or 5000 units SC qd *or* Fondaparinux 2.5 mg SC qd with normal renal function (in patients with a heparin allergy such as heparin-induced thrombocytopenia) *or* Graduated compression stockings or intermittent pneumatic compression for patients with contraindications to anticoagulation Consider combination pharmacologic and mechanical prophylaxis for high-risk patients
General surgery	Unfractionated heparin 5000 units SC bid or tid *or* Enoxaparin 40 mg SC qd *or* Dalteparin 2500 or 5000 units SC qd
Major orthopedic surgery	Warfarin (target INR 2 to 3) *or* Enoxaparin 30 mg SC bid *or* Enoxaparin 40 mg SC qd *or* Dalteparin 2500 or 5000 units SC qd *or* Fondaparinux 2.5 mg SC qd *or* Rivaroxaban 10 mg qd *or* Aspirin 81 mg qd *or* Dabigatran 220 mg qd *or* Apixaban 2.5 mg twice daily *or* Intermittent pneumatic compression (with or without pharmacologic prophylaxis)

bid, Twice daily; *INR,* international normalized ratio; qd, every day; *SC*, subcutaneous; *tid,* three times a day.

BOX 3 Traditional Absolute and Relative Contraindications to Pharmacologic and Mechanical Venous Thromboembolism Prophylaxis[a]

Contraindications to Pharmacologic Prophylaxis
- Active, recent, or high risk of clinically significant bleeding
- Thrombocytopenia (platelet count <50,000/μL)
- Systemic coagulopathy (e.g., disseminated intravascular coagulation, international normalized ratio >1.4, or activated partial thromboplastin time ratio >1.2, excluding lupus inhibitors)
- Known congenital bleeding disorders (e.g., hemophilia A or B and von Willebrand disease)
- Known functional acquired or congenital platelet disorder (e.g., Bernard-Soulier syndrome and uremic platelet dysfunction)
- Heparin-induced thrombocytopenia (for unfractionated or low-molecular-weight heparin)

Contraindications to Mechanical Prophylaxis
- Acute or recent deep venous thrombosis (within 3 mo)
- Arterial insufficiency in target limb
- Open lower extremity wound

[a]List not inclusive.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 6 Management of Recurrent Venous Thromboembolism in Patients with Cancer

Causes	Management
Extrinsic vascular compression (causes sluggish flow)	Relieve vascular compression due to tumor, nodal masses, or anatomic abnormalities (i.e., May-Thurner syndrome/iliac vein compression, thoracic outlet syndrome) with surgical decompression, vascular stents, or other
Intrinsic vascular obstruction	Remove central venous catheter or devices responsible for sluggish flow
Trousseau syndrome	Switch to LMWH
Heparin-induced thrombocytopenia	Discontinue unfractionated or LMWH and start a direct thrombin inhibitor (preferred) or fondaparinux
Therapeutic resistance	If the patient is taking warfarin, switch to LMWH If the patient is taking LMWH, check to ensure the correct full weight-based dose is being used, switch to twice-daily dosing (if administration is once daily), consider checking LMWH (anti-Xa) level, initiate an empiric 25% dose increase, or switch to fondaparinux

LMWH, Low-molecular-weight heparin.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

contraindicated in pregnancy. Low-molecular-weight heparins are safe and effective. Typical agents used in pregnancy include dalteparin (200 IU per kilogram of body weight daily or 100 IU per kilogram twice daily) or enoxaparin (1.5 mg per kilogram daily or 1 mg per kilogram twice daily).

- ***REVERSAL OF ANTICOAGULATION:*** Vitamin K (1 mg PO or 2 mg IV) can be used to reverse elevated INR (3 to 6) from warfarin when elective or urgent procedures are needed. The administration of vitamin K can take more than 24 hr to fully restore vitamin K dependent coagulation factors II, VII, IX, and X. The American College of Chest Physicians recommends the following guidelines for managing elevated INRs or bleeding in patients receiving vitamin A antagonist therapy:
  1. INR between 4.5 and 10 and no significant bleeding: Omit dose and monitor the next day, routine use of vitamin K is not recommended.
  2. INR >10 and no significant bleeding: Hold vitamin K antagonist, give 5 to 10 mg orally of vitamin K. Monitor the next day and use additional vitamin K if necessary. Resume therapy at lower dose when INR therapeutic.
  3. Serious bleeding at any elevation of INR: Hold vitamin K antagonist and supplement with prothrombin complex concentrates (PCC). Give vitamin K (10 mg by slow IV infusion over 30 min to reduce the risk of anaphylaxis). Vitamin K1 can be repeated every 12 hr. PCC composition in the U.S. (3-factor PCC) includes clotting factors II, IX, and X but minimal amounts of factor VII (unlike PCC products available outside of the U.S. [4-factor PCC], which have a significant amount of factor VII). In order to replace the low factor VII, some clinicians in the U.S. will also give fresh frozen plasma (FFP) in addition to vitamin K and PCC in patients with life-threatening warfarin-related bleeding.
- ***SPECIFIC REVERSAL AGENTS FOR NON–VITAMIN K ANTAGONIST ANTICOAGULANTS*** (**Table 7**):
  1. Idarucizumab, an antibody fragment given at a dose of 5 g IV, has been shown to completely reverse the anticoagulant effect of dabigatran within minutes.
  2. The anticoagulant activity of factor Xa inhibitors apixaban, rivaroxaban, and edoxaban can be rapidly reversed with IV administration of andexanet alfa.
  3. These reversal agents are very expensive (over $20,000 for each use).

TABLE 7 Reversal Agents for Direct Oral Anticoagulants

Feature	Idarucizumab	Andexanet Alfa	Ciraparantag
Structure	Humanized antibody fragment	Recombinant human factor Xa variant	Synthetic, small cationic molecule
Mass (Da)	47,776	39,000	573
Mechanism of action	Binds dabigatran with high affinity	Competes with factors Xa (and IIa) for binding	Binds via hydrogen bonding
Target	Dabigatran	Rivaroxaban, apixaban, edoxaban and heparins	Dabigatran, rivaroxaban, apixaban, edoxaban and heparins
Administration	Intravenous bolus	Intravenous bolus followed by a 2-hour infusion	Intravenous bolus
Measurement of reversal	Activated partial thromboplastin time, diluted thrombin time, or ecarin clotting time or chromogenic assay	Calibrated anti-factor Xa assays	Whole-blood clotting time
Elimination	Renal (catabolism)	Not reported	Not reported
Cost	$3500 per dose in the U.S.	Unknown; likely to be at least as much as idarucizumab	Likely to be low

From Zipes DP: *Braunwald's heart disease, a textbook of cardiovascular medicine*, ed 11, Philadelphia, 2019, Elsevier.

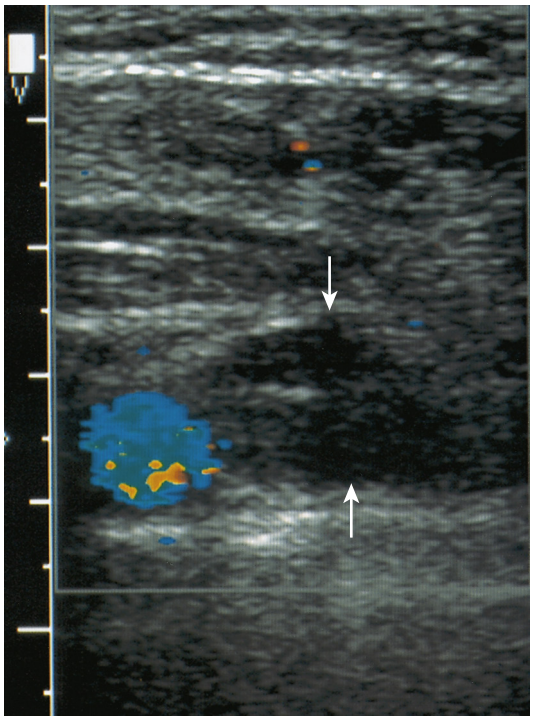

FIG. E2 Doppler ultrasound appearance of deep vein thrombosis. The superficial femoral vein is filled with echogenic material representing thrombus, and no flow can be identified in the vein on Doppler evaluation. Flow can be identified in the adjacent artery on color Doppler evaluation *(arrows).* (From Crawford MH, et al.: [eds]: *Cardiology,* ed 2, St Louis, 2004, Mosby.)

BASIC INFORMATION

DEFINITION

Delayed puberty is clinically defined as the absence of or incomplete development of secondary sexual characteristics by an age at which 95% of the population begins to mature sexually. For girls, a delay is defined as an absence of breast development by age 13 or primary amenorrhea by age 16. For boys, a delay is classified as an absence of testicular enlargement by age 14.

SYNONYM

Pubertal delay

ICD-10CM CODE
E30.0 Delayed puberty

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The actual prevalence and incidence for children presenting with delayed puberty is unknown. Delayed puberty is more common in boys.

GENETICS: Constitutional pubertal delay (CPD) often runs in families. Although specific gene mutations have yet to be identified, studies have shown that 50% to 75% of patients with CPD have at least one parent who experienced a delay in puberty. The inheritance pattern for CPD is thought to be autosomal dominant.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Girls with pubertal delay have an absence of breast development by age 13, absence of menarche by age 16, or absence of menarche within 3 yr of thelarche. Boys with pubertal delay show no evidence of testicular enlargement, further defined as testes <2.5 cm, by age 14. Absence of pubic and/or axillary hair is common, as is lack of growth spurt.
- Patients with a constitutional delay in puberty are short in stature with a normal growth rate and otherwise good health.
- Boys often fall below the 10th percentile on a height chart with normal rate of growth between 4 and 6 cm per yr.

ETIOLOGY

Causes for pubertal delay (Fig. E1) can be separated into four categories (from most to least common):

1. Constitutional delay, which is a temporary delay in puberty that is seen mostly in boys and is genetic. Patients are typically short in stature with normal growth rate and appropriate skeletal age.
2. Functional hypogonadotropic hypogonadism secondary to malnutrition or chronic disease. Celiac sprue, inflammatory bowel disease (IBD), hypothyroidism, diabetes mellitus, cystic fibrosis, and eating disorders such as anorexia nervosa are examples of illnesses that may cause a temporary, reversible delay in puberty. Clinical suspicion is warranted when underweight children present with pubertal delay.
3. Hypergonadotropic hypogonadism caused by primary gonadal failure. Congenital disorders such as cryptorchidism; chromosomal disorders such as gonadal dysgenesis, Klinefelter syndrome, and Turner syndrome; and acquired causes secondary to chemotherapy, pelvic radiation, and gonadal surgery are organic dysfunctions that result in gonadal failure despite adequate hypothalamic-pituitary function. In this group of disorders, luteinizing hormone (LH) and follicle-stimulating hormone (FSH) levels are elevated yet cannot stimulate ovaries and testicles to produce estrogen and testosterone, respectively, leading to hypogonadism and absence of secondary sex characteristics.
4. Permanent hypogonadotropic hypogonadism secondary to genetic or acquired defects along the hypothalamic-pituitary-gonadal (HPG) axis. Kallmann syndrome is a genetic mutation in *KAL1* on the X chromosome and is responsible for the migration of gonadotropin-releasing hormone and olfactory neurons into the hypothalamus. Children with Kallmann syndrome typically present with pubertal delay and anosmia. Other mutations such as *FGFR1* and *DAX1* have been linked to congenital gonadotropin deficiencies and pubertal delay. Acquired defects such as hemochromatosis, sickle cell anemia, and pituitary tumors can cause delayed puberty and other hypothalamic syndromes, including Prader-Willi. Table E1 provides a classification of puberty and sexual infantilism.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Normal or low serum LH and FSH

- Constitutional pubertal delay
- Functional hypogonadotropic hypogonadism:
  1. Malnutrition or eating disorder
  2. Strenuous exercise
  3. Chronic illness (e.g., hypothyroidism, celiac disease, IBD, cystic fibrosis)
- Hypopituitarism:
  1. Panhypopituitarism
  2. Isolated gonadotropin deficiency
  3. Kallmann syndrome (associated with anosmia)
  4. Prader-Willi syndrome
- Hyperprolactinemia:
  1. Pituitary adenoma
  2. Drug-associated (e.g., cannabis, cocaine)

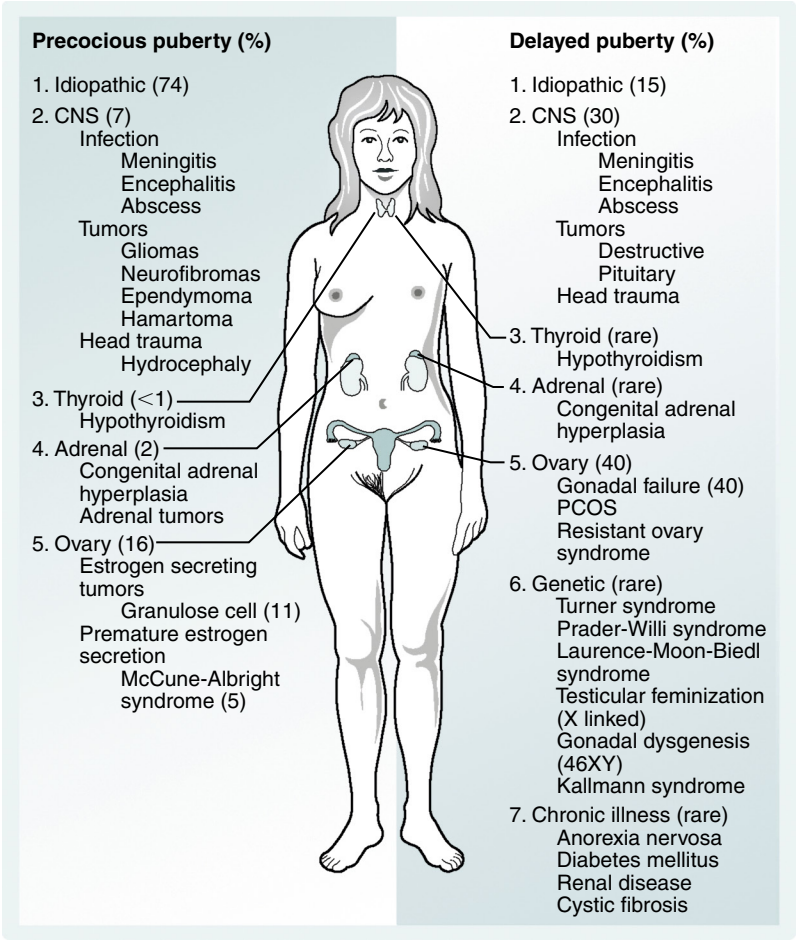

FIG. E1 Causes of precocious puberty and delayed puberty. CNS, Central nervous system; PCOS, polycystic ovarian syndrome. (From Pariseai M: Gynaecological endocrinology. In Pariseai M et al [eds]: *Obstetrics and gynaecology,* St Louis, 2008, Mosby.)

TABLE E1 Differential Diagnostic Features of Delayed Puberty and Sexual Infantilism

Condition	Stature	Plasma Gonadotropins	GnRH Test LH Response	Plasma Gonadal Steroids	Plasma DHEAS	Karyotype	Olfaction
Constitutional delay in growth and adolescence	Short for chron. age, usually appropriate for bone age	Prepubertal, later pubertal	Prepubertal, later pubertal	Low, later normal	Low for chron. age, appropriate for bone age	Normal	Normal
Hypogonadotropic Hypogonadism							
Isolated gonadotropin deficiency	Normal, absent pubertal growth spurt	Low	Prepubertal or no response	Low	Appropriate for chron. age	Normal	Normal
Kallmann syndrome	Normal, absent	Low	Prepubertal or no response	Low	Appropriate for chron. age	Normal	Anosmia; pubertal growth spurt or hyposmia
Idiopathic multiple pituitary hormone deficiencies	Short stature and poor growth since early childhood	Low	Prepubertal or no response	Low	Usually low	Normal	Normal
Hypothalamic-pituitary tumors	Late-onset decrease in growth velocity	Low	Prepubertal or no response	Low	Normal or low for chron. age	Normal	Normal
Primary Gonadal Failure							
Syndrome of gonadal dysgenesis (Turner syndrome) and variants	Short stature since childhood	High	Hyperresponse for age	Low	Normal for chron. age	45,X or variant	Normal
Klinefelter syndrome and variants	Normal to tall	High	Hyperresponse at puberty	Low or normal	Normal for chron. age	47,XXY or variant	Normal
Familial XX or XY gonadal dysgenesis	Normal for age	High	Hyperresponse	Low	Normal for chron. age	46,XX or 46,XY	Normal

chron., Chronologic; *DHEAS*, dehydroepiandrosterone sulfate; *GnRH*, gonadotropin-releasing hormone; *LH*, luteinizing hormone.
From Melmed S et al: *Williams textbook of endocrinology*, ed 12, Philadelphia, 2011, Saunders.

3. Increased serum gonadotropins
- Hypergonadotropic hypogonadism:
  1. Turner syndrome (gonadal dysgenesis)
  2. Klinefelter syndrome
  3. Gonadal dysgenesis
  4. Noonan syndrome
  5. Bilateral gonadal failure:
     a. Primary testicular failure
     b. Anorchia
     c. Premature ovarian failure
     d. Resistant ovary syndrome
     e. Radiation, chemotherapy
     f. Trauma
     g. Infections (e.g., mumps, orchitis)

Other conditions
- Androgen sensitivity syndrome
- Steroidogenic enzyme defects

WORKUP

- Given the extensive differential diagnosis for pubertal delay, a systematic and focused approach is necessary. Table E2 describes a classification of delayed puberty and sexual infantilism. A careful history, including family and social history, can identify eating, exercise habits, chronic illnesses, weight loss, poor weight gain, changes in bowel habits, and parental history of pubertal delay. Figs. E2 and E3 describe an algorithm for the evaluation of delayed puberty in males and females.
- Growth measurement should include height and weight, a growth chart to assess rate of growth, and calculation of the sex-adjusted midparental height that represents the statistically probable adult height for the child.
  1. For boys, add 2.5 inches (6.5 cm) from the mean of the parents' heights. For girls, subtract 2.5 inches (6.5 cm) from the mean of the parents' heights.
  2. Physical exam can reveal signs of sexual maturation, stigmata of congenital syndromes, and nutritional deficiencies. It is important to include a neurologic (visual fields, ophthalmologic), thyroid, respiratory, cardiovascular, and abdominal examination, in addition to evaluation of the Tanner stages of sexual characteristics.

LABORATORY TESTS

- Serum LH, FSH, testosterone, and estradiol can help distinguish disorders of congenital or acquired gonadal failure from other causes. By the age of 10 to 12 yr gonadal failure produces elevated levels of serum LH and FSH. If levels are low or normal, constitutional delay is the most common diagnosis.
- Chromosomal analysis is indicated if there is a suspicion of gonadal dysgenesis or Klinefelter syndrome.
- Screening studies include complete blood count, erythrocyte sedimentation rate, prolactin, thyroid-stimulating hormone, and free thyroxine level.
- Endocrinologist may incorporate further studies such as IGF-1 to screen for growth hormone disorders and GnRH stimulation testing.

IMAGING STUDIES

Bone age skeletal radiograph of the left hand and wrist determines skeletal age, which is delayed in constitutional delay and GnRH deficiency. MRI of the head should be considered if there is high clinical suspicion for tumors of pituitary or hypothalamic origin. Pelvic ultrasound can be helpful in detecting intraabdominal testes and evaluating müllerian anatomy.

Rx TREATMENT

- Treat underlying cause.
- Constitutional delay can be managed with reassurance that the delay will have no effect on the final adult height or overall

TABLE E2 Classification of Delayed Puberty and Sexual Infantilism

Idiopathic (Constitutional) Delay in Growth and Puberty (Delayed Activation of Hypothalamic LRF Pulse Generator)

Hypogonadotropic Hypogonadism: Sexual Infantilism Related to Gonadotropin Deficiency

CNS Disorders

Tumors

- Craniopharyngiomas
- Germinomas
- Other germ cell tumors
- Hypothalamic and optic gliomas
- Astrocytomas
- Pituitary tumors (including MEN-1, prolactinoma)

Other Causes

- Langerhans histiocytosis
- Postinfectious lesions of the CNS
- Vascular abnormalities of the CNS
- Radiation therapy
- Congenital malformations especially associated with craniofacial anomalies
- Head trauma
- Lymphocytic hypophysitis

Isolated Gonadotropin Deficiency

- Kallmann syndrome
- With hyposmia or anosmia
- Without anosmia
- LHRH receptor mutation
- Congenital adrenal hypoplasia (*DAX1* mutation)
- Isolated LH deficiency
- Isolated FSH deficiency
- Prohormone convertase 1 deficiency (PCI)

Idiopathic and Genetic Forms of Multiple Pituitary Hormone Deficiencies Including Prop1 Mutation

Miscellaneous Disorders

- Prader-Willi syndrome
- Laurence-Moon and Bardet-Biedl syndromes
- Functional gonadotropin deficiency
- Chronic systemic disease and malnutrition:
  1. Sickle cell disease
  2. Cystic fibrosis
  3. Acquired immunodeficiency syndrome (AIDS)
  4. Chronic gastroenteric disease
  5. Chronic renal disease
- Malnutrition
- Anorexia nervosa
- Bulimia
- Psychogenic amenorrhea
- Impaired puberty and delayed menarche in female athletes and ballet dancers (exercise amenorrhea)
- Hypothyroidism
- Diabetes mellitus
- Cushing disease
- Hyperprolactinemia
- Marijuana use
- Gaucher disease

Hypergonadotropic Hypogonadism

Males

- The syndrome of seminiferous tubular dysgenesis and its variants (Klinefelter syndrome)
- Other forms of primary testicular failure:
  1. Chemotherapy
  2. Radiation therapy
  3. Testicular steroid biosynthetic defects
  4. Sertoli-only syndrome
  5. LH receptor mutation
  6. Anorchia and cryptorchidism
- Trauma/surgery

Females

- The syndrome of gonadal dysgenesis (Turner syndrome) and its variants
- XX and XY gonadal dysgenesis
- Familial and sporadic XX gonadal dysgenesis and its variants
- Familial and sporadic XY gonadal dysgenesis and its variants
- Aromatase deficiency
- Other forms of primary ovarian failure
- Premature menopause
- Radiation therapy
- Chemotherapy
- Autoimmune oophoritis
- Galactosemia
- Glycoprotein syndrome type 1
- Resistant ovary
- FSH receptor mutation
- LH/hCG resistance
- Polycystic ovarian disease
- Trauma/surgery
- Noonan or pseudo-Turner syndrome
- Ovarian steroid biosynthetic defects

CNS, Central nervous system; *FSH,* follicle-stimulating hormone; *hCG,* human chorionic gonadotropin; *LHRH,* luteinizing hormone–releasing hormone; *LRF,* luteinizing hormone–releasing factor; *MEN,* multiple endocrine neoplasia.

From Styne DM, Grumbach MM: Physiology and disorders of puberty. In Melmed S, Polonsky KS, Larsen PR, Kronenberg HM [eds]: *Williams textbook of endocrinology,* ed 13, Philadelphia, 2016, Elsevier, Table 25.15, p. 1129; and Kliegman RM: *Nelson Textbook of Pediatrics,* ed 21, Philadelphia, 2020, Elsevier.

development. Short-term hormonal therapy can be used to hasten puberty if the delay is causing severe psychosocial difficulties. Oxandrolone orally can be given daily or IM depot testosterone q6wk for 3 to 6 mo for boys to improve velocity of growth. Girls can receive oral estradiol once daily for 3 to 6 mo.

- Malnutrition and chronic disease can best be treated by correcting the underlying etiology. A short (3 to 6 mo) treatment course, as described above, may be indicated for children with psychosocial difficulties.
- Permanent causes of pubertal delay can be treated by inducing puberty with testosterone for boys and estrogen plus progesterone for girls.
- Patients with Turner syndrome will need adjunct growth hormone with or without oxandrolone.
- Gonadotropin deficiency or hypogonadism may require lifelong sex steroid replacement.
- Psychosocial evaluation, support, and treatment as needed.
- Table E3 summarizes the management and treatment of delayed puberty.

REFERRAL

Pediatric endocrinology

PEARLS & CONSIDERATIONS

COMMENTS

- Constitutional delay is the most common cause of pubertal delay and is often associated with a positive family history in parents and/or siblings, but it is a diagnosis of exclusion, so other causes, such as Turner syndrome and systemic disorders, need to be ruled out first.
- Bone age demonstrates more clearly than chronologic age how far an individual has progressed toward maturity and predicts the potential for further growth.
- No studies reliably differentiate constitutional delay from gonadotropin deficiency.

TABLE E3 Management and Treatment of Delayed Puberty

Objective

- Determine site and etiology of abnormality
- Induce and maintain secondary sexual characteristics
- Induce pubertal growth spurt
- Prevent the potential short-term and long-term psychological, personality, and social handicaps of delayed puberty
- Ensure normal libido and potency
- Attain fertility

Therapy

Concerned but Not Anxious or Socially Handicapped Adolescent

- Reassurance and follow-up (tincture of time)
- Repeat evaluation (including serum testosterone or estradiol) in 6 mo

Psychosocial Handicaps, Anxiety, Highly Concerned

Therapy for 4 mo

- *Boys:* Testosterone enanthate 100 mg IM q4wk at 14-14.5 yr of age, or overnight transdermal testosterone patch
- *Girls:* Ethinyl estradiol 5-10 mg/day PO or conjugated estrogens 0.3 mg/day PO or overnight ethinyl estradiol patch at 13 yr of age
- No therapy for 4-6 mo; reevaluate status including serum testosterone or estradiol; if indicated, repeat treatment regimen

IM, Intramuscular; *PO,* by mouth.
From Melmed S et al: *Williams textbook of endocrinology*, ed 12, Philadelphia, 2011, Saunders.

BASIC INFORMATION

DEFINITION

The American Psychiatric Association's *Diagnostic and Statistical Manual*, 5th edition, (DSM-5) defines delirium as:

- Disturbance of consciousness with reduced ability to focus, sustain, or shift attention.
- The disturbance develops over a short period of time (usually hours to days) and tends to fluctuate during the course of a day.
- An additional disturbance in cognition (e.g., memory deficit, disorganization, language, visuospatial ability, or perception).
- A change in cognition or development of a perceptual disturbance that is not better accounted for by a preexisting, established, or evolving dementia.
- There is evidence from history, physical exam, or lab findings that the disturbance is caused by medical condition, substance intoxication or withdrawal (i.e., due to a drug of abuse or to a medication), or exposure to a toxin, or is due to multiple etiologies.

SYNONYMS

Acute confusional state
Toxic or metabolic encephalopathy

THEORIES REGARDING PATHOPHYSIOLOGY

- Neuroinflammation, with increased permeability of the blood-brain barrier
- Acetylcholine deficiency
- Other neurotransmitter imbalances, including excesses of norepinephrine, serotonin, and, most important, dopamine

CLASSIFICATION

Hyperactive, hypoactive, and mixed subtype

ICD-10CM CODES

F05	Delirium, not induced by alcohol and other psychoactive substances
F05.9	Delirium, unspecified
F06.0	Organic hallucinosis
F05.8	Other delirium
F05.0	Delirium not superimposed on dementia
F05.1	Delirium superimposed on dementia

EPIDEMIOLOGY & DEMOGRAPHICS

Nearly 30% of older patients experience delirium at some time during the hospital course. In old surgical patients, the risk varies from 10% to 50%. Hypoactive is more common. Delirium is the most common mental disorder in patients with medical illness. Any age, race, or gender can be affected. Pediatric delirium is often missed but remains important because delirium is associated with longer hospital stays, decreased cognitive performance, and increased mortality. Risk factors include extremes of age, severe pain, illicit substance use, surgery, dementia, and kidney or liver failure (Table 1).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- One of the earliest symptoms is change in level of awareness and ability to focus, sustain, or shift attention. Symptoms may differ both among patients and within one patient. Family members or caregivers report that the patient "isn't acting quite right." Symptoms may include poor attention, sleepiness, agitation, or psychosis.
- Acuteness of presentation helps in differentiating delirium with dementia. Change in cognition, perceptual problems (such as visual, auditory, or somatosensory hallucination usually with lack of insight), memory loss, disorientation, difficulty with speech and language. It is important to ascertain from family member or caregivers the patient's level of functioning before onset of delirium.
- Elderly patients with delirium often do not look sick, but patients with delirium are sick by definition.
- Hyperactive delirium represents only 25% of cases, with the others having hypoactive (quiet) delirium.
- There is often a prodrome phase that later blends into hypoactive delirium or erupts into an agitated confusional state.
- Physical examination should be performed, focusing on signs of infection, dehydration, or chronic disease that may be exacerbated. Vital signs are key. Consider using the Mini-Mental Status Exam or the Montreal Cognitive Assessment.
- Fig. 1 describes an algorithm for evaluation of mental status changes in an older patient.
- Table 2 summarizes delirium assessment tools.

ETIOLOGY

Can be multifactorial; often falls into one of the following categories:

- Drugs: Benzodiazepines are the worst offenders, but other drugs such as narcotics, anticholinergics, beta-blockers, steroids, nonsteroidal antiinflammatory drugs, digoxin, cimetidine can cause delirium; also, withdrawal states such as alcohol withdrawal or benzodiazepine withdrawal can cause delirium
- Infection or inflammation
- Metabolic: Kidney or liver failure, thyroid, adrenal, or glucose dysregulation, anemia, vitamin deficiency such as Wernicke encephalopathy or vitamin B_{12} deficiency, inborn metabolic errors such as porphyrias or Wilson disease
- Stress: Surgery, sleep problems, pain, fever, hypoxia, anesthesia, environmental changes, fecal or urinary retention, burns
- Fluids, electrolytes, nutrition (FEN): Dysregulation of calcium, magnesium, potassium, or sodium; dehydration; volume overload; altered pH
- Brain disorder: CNS infection, head injury, hypertensive encephalopathy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary psychiatric illness
- Focal syndromes
- Dementia
- Sundowning
- Nonconvulsive status epilepticus

Remember, delirium may coexist with any of the above. Table 3 summarizes the differential diagnosis of delirium. Table 4 describes clinical factors that help differentiate delirium and dementia from psychiatric disease.

LABORATORY TESTS

- Complete blood count, electrolytes, liver function tests, ammonia, drug levels (digoxin, lithium)
- Toxicology screen, urinalysis, urine culture
- Thyroid function tests, vitamin B_{12}, and folate levels
- Rapid plasma reagin for syphilis, blood, urine, and spinal fluid culture
- Arterial blood gas
- Lumbar puncture is mandatory when cause of delirium is not obvious

IMAGING STUDIES

- Consider head CT (to look for bleed, trauma, tumor, atrophy, dementia, stroke)
- Chest radiograph (to look for tumor, infection)

TABLE 1 Mnemonic for Risk Factors for Delirium and Agitation

I Watch Death	Delirium
Infection	**D**rugs
Withdrawal	**E**lectrolyte and physiologic abnormalities
Acute metabolic	**L**ack of drugs (withdrawal)
Trauma/pain	**I**nfection
Central nervous system pathology	**R**educed sensory input (blindness, deafness)
Hypoxia	**I**ntracranial problems (CVA, meningitis, seizure)

ELECTROENCEPHALOGRAM

To exclude seizure, confirm diagnosis of metabolic encephalopathy

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The most important consideration is to keep the patient safe by using a variety of methods, including frequent reorientation.
- A quiet, restful, simplified environment with cues to time and location such as clock or calendar is helpful, as well as consistent staff providing both personal and medical care. If possible, encourage familiar family members and friends to keep the patient company.
- Early mobilization and minimized use of physical restraints (use of physical restraints if necessary to ensure safety).
- Visual and hearing aids for patients with these impairments.

ACUTE GENERAL Rx

- Reverse any treatable cause, such as volume repletion for patients with dehydration, antibiotics for urinary tract infection.
- Antipsychotic agents should not be used routinely for preventing or treating delirium. Pharmacologic treatment with antipsychotic agents should be initiated only when symptoms are severe, dangerous, or cause significant distress to the patient. In general these agents are similarly effective and the choice among them is usually made on the basis of side effects. Haloperidol is the least sedating but has a high risk of extrapyramidal side effects; quetiapine has the fewest side effects but is highly sedating.
- Haloperidol can be used with caution to control agitation, with doses ranging from 0.25 to 2 mg IM/IV twice daily, repeating the dose every 20 to 30 min until patient has calmed and using lower doses for the elderly.
- Most antipsychotics can prolong the QT interval and increase the risk of torsades de

TABLE 3 Differential Diagnosis of Delirium

General Cause	Specific Cause
Vascular	Hypertensive encephalopathy Cerebral arteriosclerosis Intracranial hemorrhage or thrombosis Emboli from atrial fibrillation, patent foramen ovale, or endocarditic valve Circulatory collapse (shock) Systemic lupus erythematosus Polyarteritis nodosa Thrombotic thrombocytopenic purpura Hyperviscosity syndrome Sarcoid Posterior reversible encephalopathy syndrome (PRES) Cerebral aneurysm
Infectious	Encephalitis Bacterial or viral meningitis, fungal meningitis (*cryptococcal*, *coccidioidal*, *histoplasma*) Sepsis General paresis Brain, epidural, or subdural abscess Malaria Human immunodeficiency virus Lyme disease Typhoid fever Parasitic (*toxoplasma*, *trichinosis*, *cysticercosis*, *echinococcosis*) Behçet syndrome Mumps
Neoplastic	Space-occupying lesions, such as gliomas, meningiomas, abscesses Paraneoplastic syndromes Carcinomatous meningitis
Degenerative	Dementias Huntington disease Creutzfeldt–Jakob disease Wilson disease
Intoxication	Chronic intoxication or withdrawal effect of drugs, including sedative-hypnotics, opiates, tranquilizers, anticholinergics, dissociative anesthetics, anticonvulsants
Neurophysiologic	Epilepsy Postictal states Complex partial status epilepticus
Traumatic	Intracranial bleeds Postoperative trauma Heat stroke Fat emboli syndrome

Continued

TABLE 3 Differential Diagnosis of Delirium—cont'd

General Cause	Specific Cause
Intraventricular	Normal-pressure hydrocephalus
Vitamin deficiency	Thiamine (Wernicke–Korsakoff syndrome) Niacin (pellagra) B_{12} (pernicious anemia)
Endocrine/metabolic	Diabetic coma and shock Uremia Myxedema Hyperthyroidism Parathyroid dysfunction Hypoglycemia Hepatic or renal failure Porphyria Severe electrolyte or acid/base disturbances Cushing or Addison syndrome Sleep apnea Carcinoid Whipple disease
Autoimmune	Autoimmune encephalitides Steroid-responsive encephalopathy associated with thyroiditis (SREAT)/ Hashimoto encephalopathy Systemic lupus erythematosus Multiple sclerosis
Poisoning	Heavy metals (lead, manganese, mercury) Carbon monoxide Anticholinergics Other toxins
Anoxia	Hypoxia and anoxia secondary to pulmonary or cardiac failure, anesthesia, anemia
Psychiatric	Depressive pseudodementia, catatonia, Bell mania

Stern TA et al: *Massachusetts General Hospital handbook of general hospital psychiatry, ed 7, Philadelphia*, 2017, Elsevier.

pointes. The effect is greatest with IV haloperidol and least with aripiprazole. Aripiprazole is available in tablets, solution, and injection. Starting dose is 1 mg twice a day.

- Risperidone 0.5 mg twice daily (off-label use, non-FDA approved) can also be used with caution with a slow increase to desired dose, not to exceed 1.0 to 2.0 mg.
- Avoid benzodiazepines and meperidine. Drug toxicity accounts for approximately 30% cases of delirium.

CHRONIC Rx

Delirium is not a chronic condition; if assessing a more long-term mental status change, consider other diagnoses.

DISPOSITION

Requires frequent monitoring often necessitating hospital level of care to ensure safety and assess etiology.

REFERRAL

Consider neurologic or psychiatric consultation if not improved in several days or in complicated cases.

PEARLS & CONSIDERATIONS

COMMENTS

Although benzodiazepines are frequently used in hospitalized patients for sedation and are the mainstay of therapy for alcohol withdrawal, they must be used with caution in the elderly because they can have a paradoxical effect on agitation.

PREVENTION (TABLE 5)

- Avoid polypharmacy as much as possible.
- Optimize chronic medical conditions.
- Provide frequent reorientation and a soothing environment for high-risk patients (e.g., lights on during the day, off at night; open curtains during the day so patient can see the weather).
- In patients over 70 without dementia, regular exercise has been associated with lower risk for developing delirium, and early return to physical activity can improve outcomes in ill patients.

PATIENT & FAMILY EDUCATION

Inform about the above preventive techniques, especially polypharmacy risks.

TABLE 4 Clinical Factors That Help Differentiate Delirium and Dementia from Psychiatric Disease

Characteristic	Delirium	Dementia	Psychiatric Illness
Symptoms			
Age at onset	<12 or >40 yr	Usually elderly, >50 yr	13-40 yr
Onset	Acute	Gradual or insidious	Gradual
Symptom course	Rapid, fluctuating	Stable and progressive	Stable
Duration	Days to weeks	Months to years	Months to years
Reversibility	Usually	Rarely	Rarely
History			
Past medical history	Substance abuse, medical illness	Comorbid conditions of aging	Previous psychiatric history
Family history	Unusual	History of dementia	History of psychiatric illness
Physical Examination			
Vital signs	Usually abnormal	Usually normal	Usually normal
Involuntary activity	May have tremors, asterixis, etc.	None unless coexistent disease	None
Mental Status			
Affect	Emotional lability	Flat affect with advanced disease	Flat affect
Orientation	Usually impaired	Impaired with advanced disease	Rarely impaired
Attention	Impaired	Slow to focus	Disorganized
Hallucinations	Primarily visual	Rare	Primarily auditory
Speech	Slow, incoherent, dysarthric	Usually coherent	Usually coherent
Consciousness	Decreased to impaired	Normal (clear)	Alert
Intellectual function	Usually impaired	Impaired	Intact

From Adams JG et al: *Emergency medicine, clinical essentials*, ed 2, Philadelphia, 2013, Elsevier.

TABLE 5 Priorities (Consensus, Evidence-Based, and Speculative) for the Prevention, Management, and Advancement of the Treatment of Delirium

Community-Based Prevention	Hospital-Based Prevention	Hospital-Based Management	Postdischarge Management	Clinical Research Opportunities
Hospital avoidance strategies	Implementation of basic standards (e.g., screening for delirium) Minimization of iatrogenesis*	Implementation of basic standards (e.g., review of medications)*	Responsive, proportionate, and holistic follow-up*	Pragmatic research into optimizing care delivery
Identification and management of frailty	Multicomponent interventions to address frailty† Reorientation† Nutrition† Multidisciplinary care* Physiologic correction† Sensory optimization† Minimization of ward transfers* Avoidance of polypharmacy†	Multicomponent interventions to address frailty* Reorientation* Nutrition* Multidisciplinary care* Physiologic correction* Sensory optimization* Minimization of ward transfers* Reduction of drug burden*	Identification and management of frailty Reduction and cessation of antipsychotics	The interaction between frailty, interventions to ameliorate frailty, and delirium Transference from basic science models to trials of newer therapies Validation of delirium models using advanced imaging
Pleiotropic interventions (e.g., exercise/ nutrition)	Monitor and promote early mobilization†	Monitor and promote early mobilization*	Review of the primary triggers for delirium and other state variables (e.g., mobility)	Delirium, mobility, and response to physical therapy
Early diagnosis and management of dementia	Screening for dementia*	Screening for delirium resolution and residual cognitive impairment	Screening for subsyndromal delirium or dementia*	The interaction between dementia, including non-Alzheimer dementia, and delirium
Education of nursing home facilities and staff	Education of nursing and medical staff*	Education of medical and nursing staff*	Caregiver support and education	The role of education of non-medical staff, families,‡ and general public using multimedia solutions
Integrated geriatric care for planned major surgery	Targeted drug treatments (e.g., melatonin for sleep disturbance)† Family-based screening/ reorientation†	Delirium units Supported early discharge Family-based screening/ reorientation* Management in the nursing home with CGA capability	Adaptive and versatile methods of follow-up such as telemedicine	The role of novel and targeted interventions and models of care supported by assistive technologies
Public health awareness	Audit of care and cycle of care improvement*	Audit of care and cycle of care improvement*	Public health awareness/NGO engagement	Development of key indicators in the management of delirium

CGA, Comprehensive geriatric assessment; *NGO*, nongovernmental organization.
*Consensus role.
†Evidence-based role.
‡Speculative role.

Delirium Tremens PTG

BASIC INFORMATION

DEFINITION

Delirium tremens, also known as withdrawal delirium, is overactivity of the central nervous system after cessation of alcohol intake. The time interval is variable; it usually occurs within 1 wk after reduction or cessation of heavy alcohol intake and persists for 1 to 3 days.

SYNONYMS

Withdrawal delirium
Alcohol withdrawal syndrome
DTs
Alcoholic delirium

ICD-10CM CODE

F10.231 Alcohol dependence with withdrawal delirium

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Up to 500,000 cases annually, 3% to 5% of patients who are hospitalized for alcohol withdrawal meet the criteria for withdrawal delirium
PEAK INCIDENCE: 30 yr and older
PREDOMINANT SEX: Male
PEAK AGE: Teenage yrs and older
GENETICS: More common with patients who have relatives who are alcoholics

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Ethanol withdrawal symptoms usually begin within 8 hours after blood alcohol levels decrease, peak at about 72 hours, and are markedly reduced by days 5 to 7 of abstinence
- Initially: Anxiety, insomnia, tremulousness
- Early: Tachycardia, sweating, anorexia, agitation, headache, gastrointestinal distress
- Late: Seizures, visual hallucinations, delirium

ETIOLOGY

Alcoholism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Coexisting illness
- Trauma
- Drug use

WORKUP

- Frequent rating of symptoms (hallucinations, tremor, sweating, agitation, orientation)
- The Clinical Institute Withdrawal Assessment-Alcohol (CIWA-A) scale can be used to measure the severity of alcohol withdrawal. It consists of the 10 following items:
  1. Nausea
  2. Tremor
  3. Autonomic hyperactivity
  4. Anxiety
  5. Agitation
  6. Tactile disturbances
  7. Visual disturbances
  8. Auditory disturbances
  9. Headache
  10. Disorientation

  The maximum score is 67. Scores <8 indicate mild symptoms; scores 8-15 indicate moderate withdrawal symptoms; and scores >15 indicate severe withdrawal symptoms.

LABORATORY TESTS

- Electrolytes (including magnesium, phosphate)
- Close monitoring of glucose levels
- Drug screen (blood and urine)

IMAGING STUDIES

CT scan of head if there is a history of head trauma.

TREATMENT

NONPHARMACOLOGIC THERAPY

Refer to drug rehabilitation program after patient recovers.

ACUTE GENERAL RX:

- Admission to a detoxification unit where patient can be observed closely.
- Vital signs q30min initially (neurologic signs, if necessary).
- Use of lateral decubitus or prone position if restraints are necessary.
- Nothing by mouth: Nasogastric tube for abdominal distention may be necessary but should not be routinely used.
- Vigorous hydration (4-6 L/day): IV with glucose (Na^+, K^+, PO_4^{-3}, and Mg^{2+} replacement). May be necessary in some patients but commonly there is little support for routine administration of magnesium. Use vigorous hydration with caution in patients with CHF.
- Vitamins: Thiamine 500 mg infused IV over the course of 30 minutes daily for 3 days. The initial dose of thiamine should precede the administration of IV dextrose; multivitamins (may be added to the hydrating solution).
- Sedation (sedation can be achieved using fixed-dose regimen or individualized benzodiazepine administration [see CIWA-Ar score] in "Alcohol Abuse" Chapter):
  1. Initially: Lorazepam 8 mg IM/IV every 15 minutes as needed, after the patient has received 16 mg. If delirium is still severe, administer an 8 mg bolus IV, then administer 10 to 30 mg/hr.[1]
  2. Maintenance (individualized dosage): Chlordiazepoxide, 50 to 100 mg PO q4 to 6h, lorazepam 2 mg PO q4h, or diazepam 5 to 10 mg PO tid; withhold doses or decrease subsequent doses if signs of oversedation are apparent.
  3. Midazolam is also effective for managing DTs. Its rapid onset (sedation within 2 to 4 min of IV injection) and short duration of action (approximately 30 min) make it an ideal agent for titration in continuous infusion.
- In addition to benzodiazepines, administer medications such as the antipsychotic agent haloperidol for uncontrolled agitation or hallucinations (0.5-5 mg IV/IM every 30-60 minutes as needed for severe agitation or hallucinations, not to exceed 20 mg).
- Treatment of seizures: Diazepam 2.5 mg/min IV until seizure is controlled (check for respiratory depression or hypotension) may be beneficial for prolonged seizure activity; IV lorazepam 1 to 2 mg q2h can be used in place of diazepam. In general, withdrawal seizures are self-limited and treatment is not required; the use of phenytoin or other anticonvulsants for short-term treatment of alcohol withdrawal seizures is not recommended.
- Diagnosis and treatment of concomitant medical, surgical, or psychiatric conditions.

CHRONIC Rx

Alcoholics Anonymous has the best record in breaking addiction, but the results are still disappointing.

DISPOSITION

Refer to drug rehabilitation program

REFERRAL

If cardiac arrhythmias are prominent or respiratory distress develops.

PEARLS & CONSIDERATIONS

COMMENTS

- This is a potentially lethal disease if not carefully treated. Mortality rate is 15% in untreated patients, and approximately 1% to 6% of hospitalized patients who have withdrawal delirium die.

Delusional Parasitosis

BASIC INFORMATION

DEFINITION

A fixed belief characterized by a person's preoccupation that his or her skin is infested by insects, worms, or other living organisms.

SYNONYMS

Morgellons disease
Ekbom syndrome

ICD-10CM CODE
F22 Delusional disorders
DSM-5 CODE
297.1 Delusional disorder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PEAK INCIDENCE: Occurs more often later in life
PREVALENCE: The disorder is rare. It has a prevalence estimated at 80 cases per million and appears to have a bimodal distribution peaking around ages 20 to 30 and again over 50.
PREDOMINANT SEX AND AGE: For patients less than age 50, the male/female ratio is 1:1; for patients older than 50, females predominate by a ratio of 3:1.
GENETICS: Unknown
RISK FACTORS: From 5% to 15% of individuals close to patients with delusional parasitosis will be at risk for developing shared psychotic disorder (folie a deux).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients complain of living organisms infesting their skin, sometimes including mucosal tissues.
- Patients have often been to specialists, including dermatologists, allergists, and infectious disease specialists.
- Patients may bring in samples of skin or hair, stating that they have looked at tissue under a microscope and have seen organisms. These samples are often brought in a matchbox ("matchbox sign") or wrapped in plastic wrap ("Saran sign"). This is generally called the "specimen sign."
- Skin may show areas of excoriation.

ETIOLOGY

Unknown: Thought to be mediated through dopaminergic pathways in the brain given the known etiology of other psychotic disorders and the ability of cocaine use to create symptoms of formication (see the following).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary psychiatric disorders include formication, in which patients experience crawling and biting sensations on their skin, although they are not delusional about the cause.
- Substance abuse should be considered. Case reports exist of cocaine and amphetamine use leading to these delusions.
- Delusional symptoms as the result of a primary mood disorder, such as major depression, should be considered.
- Delusional symptoms as the result of a primary psychotic disorder should be ruled out.
- Neuropsychiatric conditions: B_{12} deficiency, dementia, diabetic neuropathy, cardiovascular disease, multiple sclerosis, hyperthyroidism, and brain lesions can all cause similar delusions.
- Other medical causes that deserve workup include severe anemia, organophosphate poisoning, primary skin lesions, systemic diseases that may present with skin lesions, and disorders of infestation. There are case reports of delusional parasitosis being precipitated by herpes zoster.
- Dopaminergic agents, such as those that treat Parkinson disease, have also been shown to cause these symptoms.

WORKUP

- Skin biopsy may exclude dermatitis herpetiformis (although many patients have already been to their primary care doctor and dermatologist and have had a skin biopsy done, likely many times).
- Mineral oil preparation may exclude scabies, and a microscopic examination may exclude louse infestation.
- Thorough history is likely to yield the very fixed nature of the belief and an unwillingness to come to terms with the lack of findings on the exam.

LABORATORY TESTS

- Pruritus workup: Iron studies, LFTs, CBC, UA, TSH, chem 7, folate, B_{12}
- Lumbar puncture (especially when multiple sclerosis is highly suspected)
- CRP (especially when an inflammatory/infectious etiology is suspected)
- Urine toxicology screen to evaluate substance use

IMAGING STUDIES

- Head CT, without contrast
- MRI
- There has been evidence of environmental filaments being placed under the skin

TREATMENT

- Antipsychotics have been shown to lead to full to partial remission in approximately 65% to 75% of those treated with antipsychotics.
- Classically, pimozide (Orap) was the treatment of choice, although it has been associated with QTc prolongation.
- Multiple studies describe the use of second-generation antipsychotics and they have all shown some efficacy in small studies, but these have been shown to cause weight gain and metabolic syndrome.
- Numerous antipsychotics have a black box warning about the risk of sudden death in the elderly and must be administered carefully for patients who have issues with QTc.
- Given all of these issues, a careful risk-benefit analysis is needed, including the assistance of family members of elderly patients.

NONPHARMACOLOGIC THERAPY

- Given the fixed nature of the belief, patients often refuse referral to a mental health specialist.
- A treatment (e.g., Permethrin) should not be recommended "just in case" because it may reinforce the patient belief.
- Repeat visits with medical providers may be helpful to provide assurance and prevent harm from further workup.

ACUTE GENERAL Rx

Antipsychotics (Table E1)

TABLE E1 Antipsychotics

Antipsychotic Drug	Dosage
Haloperidol	0.5-10 mg PO bid
Pimozide	2-12 mg PO qAM
Perphenazine	4-16 mg PO tid
Olanzapine	2.5-10 mg PO bid
Aripiprazole	2.5-20 mg PO qAM
Quetiapine	12.5-200 mg PO bid
Ziprasidone	20-80 mg PO bid
Risperidone	0.5-3 mg PO bid

COMPLEMENTARY & ALTERNATIVE MEDICINE

There is no evidence on the use of complementary or alternative medicine for this disorder.

REFERRAL

Referral to an outpatient psychiatrist may be helpful, but patients are often resistant.

PREVENTION

No preventive measures have been identified.

PATIENT & FAMILY EDUCATION

Psychoeducation may be helpful for the patient and family, although resistance from the patient can be expected.

BASIC INFORMATION

DEFINITION

Dementia with Lewy bodies (DLB) is a neurodegenerative dementia occurring concurrently with or within 1 yr (either before or after) of the onset of parkinsonism. DLB also has other core features including fluctuations in attention and alertness and recurrent vivid visual hallucinations. Diagnostic criteria for dementia syndrome associated with Lewy body pathology are described in Box 1. Patients generally respond to cholinesterase inhibitors, are very sensitive to the adverse effects of neuroleptics, and compared with Parkinson disease patients, are relatively unresponsive to L-dopa.

SYNONYMS

DLB
Lewy body dementia
Diffuse Lewy body disease
Lewy body type senile dementia
Cortical Lewy body disease

ICD-10CM CODE
G31.83 Dementia with Lewy bodies

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Accounts for 10% to 15% of all dementias. DLB is the second most common neurodegenerative cause of dementia after Alzheimer disease.
PEAK INCIDENCE: Affects individuals in their sixth decade or older
PREVALENCE: Estimated 0.7% of individuals older than age 65
PREDOMINANT SEX AND AGE:
- Sex: Male predominance
- Mean age of onset: 75 yr. On average, 10 yr greater for dementia with Lewy bodies (DLB) than Parkinson disease (PD).

GENETICS:
- Most cases are sporadic with a discordance among monozygotic twins, suggesting that either environmental or other epigenetic factors may play a major role in the incidence of DLB.
- Copy number variation of the alpha-synuclein gene (*SNCA*) has been reported in families with DLB. Rare autosomal dominant variants in *LRRK2* have also been reported. These genes are associated with Parkinson disease and Parkinson disease dementia in addition to DLB, suggesting a common molecular etiology with a spectrum of clinical phenotypes.
- The *APOE* ε4 allele has a higher prevalence in DLB than in control individuals, suggesting heightened disease risk conferred by the allele. Conversely, the *APOE* ε2 allele is enriched in control individuals, suggesting a neuroprotective role, or at least the lack of a deleterious effect, for the allele.
- Other factors include glucocerebrosidase genetic mutations, high prevalence of Lewy bodies with presenilin-1 mutations, and polymorphisms of the coding region for the synuclein genes.

RISK FACTORS:
- Male sex
- Advanced age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Importance of recognizing DLB relates to its pharmacologic management, including responsiveness to cholinesterase inhibitors, sensitivity to the adverse effects of neuroleptics, and relative unresponsiveness to L-dopa.
- Onset of dementia is insidious, with core features of fluctuations in cognition, attention, and alertness; recurrent vivid visual hallucinations; and extrapyramidal motor symptoms, along with other features either suggestive or supportive of the clinical diagnosis.
- Syncopal events or unexplained episodes of severe alteration in mentation.
- Repeated falls.
- Detailed neuropsychological assessment demonstrates a characteristic profile of impairments in visuoperceptual, attentional, and executive functions, with relative sparing of episodic memory (in contradistinction to Alzheimer diseases, in which impairment in episodic memory is a hallmark), reflecting a combination of cortical and subcortical damage.

ETIOLOGY

- *SNCA* encodes for a protein normally found at the synapse with a role in vesicle production. In its insoluble form, SNCA aggregates into Lewy bodies found at the cortical and subcortical levels.
- Lewy bodies (Fig. E1) are round, eosinophilic, intracytoplasmic inclusions in the nuclei of neurons.
- Cortical Lewy bodies are found in deep cortical layers of the anterior frontal and temporal lobes, the cingulate gyrus, and insula.
- As in Parkinson disease, Lewy bodies aggregate in the following structures: substantia nigra, locus ceruleus, raphe nuclei, nucleus basalis of Meynert, and brainstem nuclei.
- Fig. 2 shows the relationships among the subtypes of dementia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diagnosis of DLB when dementia occurs before or concurrently with extrapyramidal features—arbitrarily set as the "1-yr rule" vs. Parkinson disease with dementia, which occurs in the setting of well-established Parkinson disease.
- Dementia: Alzheimer disease (AD), vascular dementia, frontotemporal dementia. However, some patients have pathological overlap of AD and DLB or DLB and vascular dementia.
- Parkinsonian features: Parkinson disease dementia, progressive supranuclear palsy (PSP), corticobasal syndrome (CBS), and multisystem atrophy (MSA).
- Rapidly progressive form: Creutzfeldt-Jakob disease (CJD). Lack of cerebellar signs and lack of typical MRI may help distinguish DLB from classic CJD (but not variant form of CJD).
- Psychiatric features: Late-onset psychosis or depression with psychotic features.
- Hallucinations with fluctuations in consciousness: Temporal lobe epilepsy (TLE) or delirium due to metabolic or autoimmune derangement.

WORKUP

- MRI of the brain to evaluate for structural causes of dementia and exclude MRI features of vascular dementia or CJD
- Lumbar puncture to rule out underlying chronic infections, especially if there are atypical features
- Electroencephalogram (EEG) if there is concern about TLE. However, both DLB and TLE may show nonspecific slowing or periodic complexes.

LABORATORY TESTS

Rule out other potential reversible causes for dementia including: Complete blood count, complete metabolic panel, thyroid stimulating hormone, and B12. Consider RPR and HIV testing as well.

IMAGING STUDIES

- MRI typically shows a relative preservation of the hippocampi and medial temporal lobe volumes (in contrast to AD) but generalized atrophy and white matter changes.

BOX 1 Diagnostic Criteria for the Dementia Syndrome Associated with Lewy Body Pathology

The cognitive disturbance is of insidious onset and is progressive, based on evidence from the history or serial cognitive examination
The presence of at least two of the following:
- Parkinsonism (rigidity, resting tremor, bradykinesia, postural instability, parkinsonian gait disorder)
- Prominent, fully formed visual hallucinations
- Substantial fluctuations in alertness or cognition
- Rapid eye movement sleep behavior disorder
- Severe worsening of parkinsonism by antipsychotic drugs
- The disturbance is not better accounted for by a systemic disease or another brain disease

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

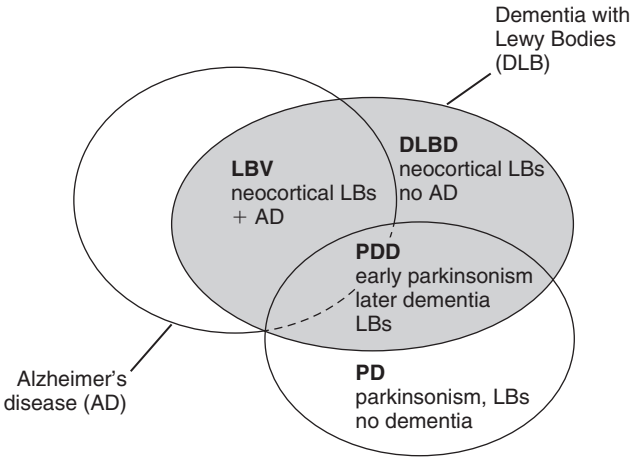

FIG. 2 Relationships among Alzheimer disease (AD), the three subtypes of dementia with Lewy bodies (DLB), and Parkinson disease (PD). Parkinsonism refers to the clinical symptoms of PD (hypokinesia, tremor, and muscular rigidity). *DLBD,* Diffuse Lewy body disease; *LBs,* Lewy bodies; *LBV,* Lewy body variant of Alzheimer disease; *PD,* Parkinson disease; *PDD,* Parkinson disease dementia. (From Lewis KA, et al.: Abnormal neurites containing C-terminally truncated α-synuclein are present in Alzheimer's disease without conventional Lewy body pathology, *Am J Pathol* 177(6):3037–3050, 2010.)

- Functional imaging including single photon emission computed tomography (SPECT) may demonstrate hypoperfusion of the occipital region (specific finding but not sensitive).

Rx TREATMENT

Patient and caregiver education about benefits, side effects, and limitations of treatment is very important. Caregivers may be encouraged to avoid neuroleptics unless the psychotic features either trouble or endanger the patient. If neuroleptics must be used, typical neuroleptics must be avoided.

NONPHARMACOLOGIC THERAPY

- Social interaction and environmental novelty may improve cognitive dysfunction and psychiatric features often exacerbated by low levels of arousal and attention
- Behavioral methods, such as avoiding previously exposed environmental triggers known to cause anxiety, agitation, or aggression
- Physical therapy, mobility aids, and daily exercise

ACUTE GENERAL Rx

Atypical neuroleptic for disabling, persistent, bothersome (to the patient) psychotic features despite initiation of a cholinesterase inhibitor. A very low dose of an atypical antipsychotic (quetiapine 12.5 mg daily) may be started after patient/caregiver education regarding the sensitivity to neuroleptics. However, all neuroleptics do carry a boxed warning from the FDA about the increased mortality risk associated with neuroleptic use in patients with dementia. Patients and/or caregivers should be informed of this risk and allowed to balance the risk against the perceived benefit.

CHRONIC Rx

- Cholinesterase inhibitors for cognitive and behavioral symptoms. Rivastigmine (6 to 12 mg per day orally or 9.5 mg per day by transdermal patch) has shown in randomized controlled trial (RCT) to significantly reduce anxiety, delusions, and hallucinations, as well as significantly improved performance on neuropsychological testing.
- Parkinson disease medications for disabling parkinsonian features. Carbidopa/levodopa is reported to be more effective with fewer side effects than dopamine agonists. Begin at a low dose—25/100 mg three times a day—and slowly titrate over several weeks as tolerated and according to response.
- Selective serotonin reuptake inhibitors are commonly used for depression.
- If rapid eye movement (REM) sleep disorder remains disabling (or patient has not responded to an atypical antipsychotic initiated for psychosis), a trial of low-dose clonazepam (0.25 to 0.5 mg) or melatonin (3 mg) at bedtime remains an option.
- Orthostatic hypotension may be aided by nonpharmacologic therapy such as supportive stockings or pharmacologically by midodrine, fludrocortisone, or droxidopa.
- Memantine demonstrated an improvement in clinical global measure and remains well tolerated but may worsen hallucinations or delusions.
- Avoid anticholinergics (including tricyclic antidepressants) and benzodiazepines, as they can trigger delirium and worsen symptoms.

DISPOSITION

- Survival resembles the progression of AD, but a minority of cases may have a rapid disease course.
- Progression in cognitive decline, similar to AD, by approximately 10% per yr on cognitive testing.

REFERRAL

DLB requires a multidisciplinary approach including the general practitioner, neurologist, neuropsychologist, and/or neuropsychiatrist.

PEARLS & CONSIDERATIONS

COMMENTS

- Clinical presentation helps differentiate DLB from AD. AD presents with early signs of anterograde episodic memory loss without the benefit of cues on neuropsychological testing due to cortical atrophy at the medial temporal lobe region.
- Vascular dementia may also present with evidence of frontal-subcortical features but typically without the core features listed in the criteria above.
- Bed partners may report that individuals with DLB "act out their dreams," sometimes violently, leading to sleeping in separate beds. This history may indicate REM sleep behavior disorder. A history of REM sleep behavior may precede the diagnosis by many yr. However, REM sleep behavior does not necessarily lead to DLB.

PATIENT & FAMILY EDUCATION

- Visual hallucinations (VH) typically consist of innocuous, well-formed, detailed images of animate figures. These are classically labeled Lilliputian, as the hallucinatory images are often relatively small. Unless VH lead to a potential threat to self or others, avoid antipsychotics due to the sensitivity of neuroleptics. Family/friends are often more alarmed by the VH than the patient with DLB.
- Apathy is a common clinical feature of DLB and mimics changes in mood, including depression or excessive daytime somnolence. These features are often noticed by family/friends.

Dengue Fever

BASIC INFORMATION

DEFINITION

Dengue fever (DF) is an infectious disease endemic in most tropical and subtropical countries. It is the most widespread arboviral illness worldwide. The causative agent is the dengue virus, a single positive-stranded RNA virus of the Flaviviridae family, which has four distinct but closely related serotypes (DEN-1, DEN-2, DEN-3, DEN-4). Dengue virus is transmitted by the *Aedes* mosquito. The primary vector is *Aedes aegypti*; the secondary vector is *Aedes albopictus*. Box E1 describes the World Health Organization case classification of dengue.

SYNONYMS

Classic dengue fever
Dengue
Dengue hemorrhagic fever
Dengue shock syndrome
DF

ICD-10CM CODES

A90 Dengue fever [classical dengue]
A91 Dengue hemorrhagic fever

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE AND PREVALENCE: The incidence of dengue is underestimated. Recent estimates indicate 390 million dengue infections per yr, of which 96 million manifest clinically. Attack rates during epidemics range from 1 to 10/1000 per yr and as high as 292/1000 among children in hyperendemic countries. There has been a thirtyfold increased incidence over the past 30 yr. During 2010 to 2017, a total of 5387 dengue cases were reported from U.S. states; 93% were travel-associated. Locally acquired cases were reported from Hawaii (<50 cases), Florida (103), Texas (24), and New York (one). Dengue is endemic in more than 100 countries in the regions of Africa, Asia, and West Pacific. Outbreaks have also occurred in Europe.

Dengue shows cyclical variation with large outbreaks every 3 to 5 yr. DF is confirmed in up to 8% of febrile travelers returning from the tropics.

RISK FACTORS: Travel to endemic regions. Few locally acquired U.S. cases have been documented in Texas, Hawaii, and Florida. The majority of indigenous cases presented as uncomplicated fever, and a minor percentage developed dengue hemorrhage fever (DHF) or dengue shock syndrome (DSS). Local transmission has also been reported in recent yrs in Europe (Southern France, Croatia, and Portugal).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation ranges from asymptomatic infection to shock syndrome.
- Symptomatic DF infection can be classified into three categories:
  1. Undifferentiated fever.
  2. Classic DF: Characterized by acute febrile illness accompanied by symptoms such as headache, retroorbital pain, fatigue, mild respiratory and gastrointestinal symptoms, and myalgias or arthralgias ("break bone fever"); DF usually follows an incubation period of 3 to 14 days and fever typically lasts 5 to 7 days; physical findings may include a maculopapular rash (Fig. E1), lymphadenopathy, pharyngeal erythema, and injected conjunctivae; some patients may experience development of hemorrhagic manifestations with petechiae, purpura (Fig. E2), and rarely, epistaxis, gum bleeding, and gastrointestinal bleeding; during pregnancy, DF has been associated with increased risk for premature labor and birth, uterine hemorrhage, intrautero death, neonatal death, and maternofetal transmission.
  3. DHF/DSS: Occurs in fewer than 3% of infected individuals; early course is similar to presentation of classic dengue, but 4 to 7 days after onset of illness, plasma leakage with hemorrhagic manifestations develops, resulting in hypoproteinemia, peripheral edema, ascites, and pleural and cardiac effusions, and is suggested by a hematocrit increase of 20% during course of illness; thrombocytopenia is also a hallmark, with resultant clinical manifestations such as petechiae, ecchymosis, mucosal hemorrhage, and GI bleeding; may progress to DSS with circulatory collapse, manifested by rapid/weak pulse, profound hypotension, and pulse pressure of <20 mm Hg; warning signs for DHF/DSS include mucosal bleed, abdominal pain, persistent vomiting, abrupt defervescence, change in mental status, and respiratory distress.

ETIOLOGY

After a bite by infected mosquito, the virus replicates in regional lymph nodes and then spreads by blood and the lymphatic system to other tissues. The incubation period is typically 4 to 7 days (range, 3 to 14 days). The most important risk factors for development of severe disease (DHF/DSS) are young age, female sex, prior infection, and viral genotype. The majority of DHF/DSS cases occur during secondary heterologous (different from first exposure) infection or during primary infection in infants born to dengue-immune mothers. In such cases, nonneutralizing cross-reactive antibodies facilitate viral entry into cells, generating higher viral burdens and stronger inflammatory responses. Additionally, T-memory cells from a previous infection are preferentially expanded because of a lower threshold of activation compared with naïve T cells of higher affinity to the current serotype. This results in suboptimal clearance of the virus and quicker, more robust cytokine production, leading to increased vascular permeability and plasma leakage. "Asian" genotypes DEN-2 and DEN-3 are associated with severe disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Influenza
- Measles
- Rubella
- Epstein-Barr virus
- West Nile virus
- HIV conversion
- Malaria
- Zika virus
- Typhoid
- Leptospirosis
- Chikungunya
- Rickettsial diseases
- Early severe acute respiratory syndrome
- Other viral hemorrhagic fevers

DHF is defined by the following World Health Organization (WHO) criteria:

- Fever lasting 2 to 7 days
- Hemorrhagic tendency (spontaneous bleeding or positive tourniquet test)
- Thrombocytopenia
- Evidence of plasma leakage

WORKUP

- Suspicion for DF based on travel, exposure history, and clinical presentation
- Tourniquet test can be performed to look for hemorrhagic manifestations; inflate blood pressure cuff midway between systolic and diastolic blood pressure for 5 min; the test result is positive when more than 20 petechial hemorrhages per square inch are counted on the forearm

BOX E1 World Health Organization Case Classification of Dengue, 2009

Dengue
Acute febrile illness, live in or travel to endemic region, with two or more of the following:
Headache or retroorbital pain
Nausea or vomiting
Rash
Aches and pains
Tourniquet test positive
Leukopenia
Any warning signs (abdominal pain, persistent vomiting, fluid accumulation, mucosal bleeding, lethargy, liver enlargement, increase in hematocrit, falling platelet count with laboratory confirmation)

Severe Dengue including Dengue Shock Syndrome
Severe capillary permeability and plasma leakage leading to dengue shock syndrome
Fluid accumulation and respiratory distress
Severe bleeding
Severe organ involvement (liver, central nervous system, heart, kidneys, and others)

From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.

LABORATORY TESTS

- CBC, liver function tests, chemistries.
- Additional laboratory tests based on differential diagnoses (e.g., malaria smears, monospot/Epstein-Barr virus titers, HIV testing).
- With compatible exposure history and symptom profile, positive anti–dengue IgM suggests recent infection, and positive anti–dengue IgG may indicate past infection.
- Confirm diagnosis with a fourfold increase of IgG and IgM between acute (<6 days after illness onset) and convalescence titers; IgM capture enzyme-linked immunosorbent assay (ELISA) commonly used, but the test result is negative early in the course of disease.
- Identification of DENV from serum by reverse transcriptase polymerase chain reaction (distributed by CDC to departments of health laboratories). Nucleic acid amplification tests (NAATs) are the preferred method of diagnosis.
- Dengue fever and Zika are closely related mosquito-borne flaviviruses with similar transmission cycles, distribution throughout the tropics and subtropics, and disease manifestations. Figs. E3 and E4 illustrate dengue and Zika virus testing recommendations for nonpregnant persons with a clinically compatible illness and risk for infection with both viruses.

IMAGING STUDIES

As dictated by clinical course

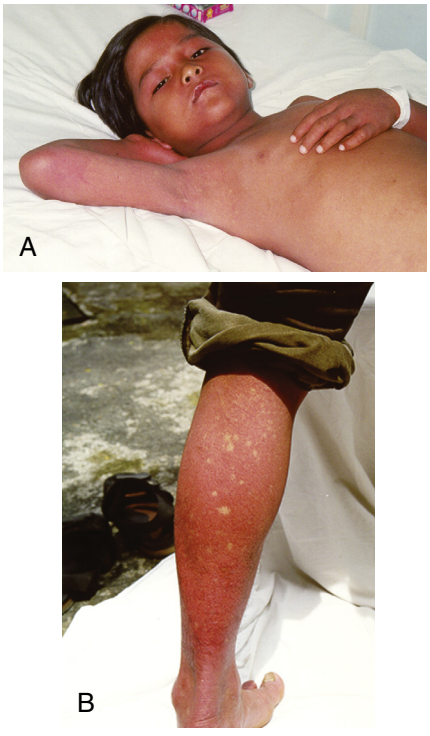

FIG. E1 Characteristic skin manifestations in convalescent dengue. A, Early convalescent macular diffuse rash occurring in the first week after recovery. **B,** Typical convalescent rash with "islands of white in a sea of red." (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.)

Rx TREATMENT

No specific pharmacologic treatment for dengue

NONPHARMACOLOGIC THERAPY

- Treatment is based on supportive measures.
- Mortality rate from DHS/DSS is improved by early and correct fluid replacement.

ACUTE GENERAL Rx

- Therapy is supportive.
- Monitor platelet count and hematocrit at least daily.
- Patients with platelet counts <100,000 have increased risk for DHF and should be monitored as inpatients.
- Hematocrit increase of 20% suggests substantial plasma loss for which patients should be admitted for intensive care and IV fluid replacement.
- Fever should be managed with acetaminophen; aspirin and NSAIDs should be avoided because of their anticoagulant properties.

DISPOSITION

- Classic dengue is usually self-limiting and rarely fatal.
- Of an estimated 500,000 cases of DHF/DSS admitted early, the mortality rate is approximately 2.5%.
- Mortality rate for DHF/DSS is as high as 20% without proper treatment but decreases to <1% with prompt recognition and appropriate treatment.

REFERRAL

- Infectious disease consultation for suspicion of DF
- Referral or transfer to center experienced with DHF/DSS if available

PEARLS & CONSIDERATIONS

COMMENTS

- Health care providers should consider dengue infection in any traveler returning from endemic areas who presents with fever.
- Given the incubation period, dengue infection can be ruled out if onset of symptoms begins 2 wk after individual leaves endemic area.
- Asymptomatic dengue infections are common; however, immunity that results from primary infection increases the risk for DHF/DSS during subsequent infections.
- Serologic testing is complicated by cross-reactions with flaviviruses (including vaccines for yellow fever and Japanese encephalitis).
- Contact the Dengue Branch at the CDC for additional information and testing (www.cdc.gov/dengue).

PREVENTION

- There is no approved vaccine against dengue in the U.S. A live attenuated tetravalent vaccine (CYD-TDV) is available outside the U.S. and recommended for use only in persons previously infected by dengue virus.[1]
- A recent phase 3 trial of a tetravalent dengue vaccine candidate (TAK-003) found it efficacious against symptomatic dengue in countries in which the disease is endemic.[2]
- For travelers, the most effective preventive measure is avoidance of mosquito bites by using protective clothing and insect repellents containing DEET.
- *Aedes* mosquitoes primarily bite during the day and typically live in urban areas.

FIG. E2 Acute skin manifestations of dengue. A, Characteristic minor bleeding near injection sites. **B,** Rash in established dengue shock syndrome. **C,** Severe bleeding after intravenous (IV) injection. Staff should press after IV injections for 5 min to ensure that bleeding stops. (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, WB Saunders.)

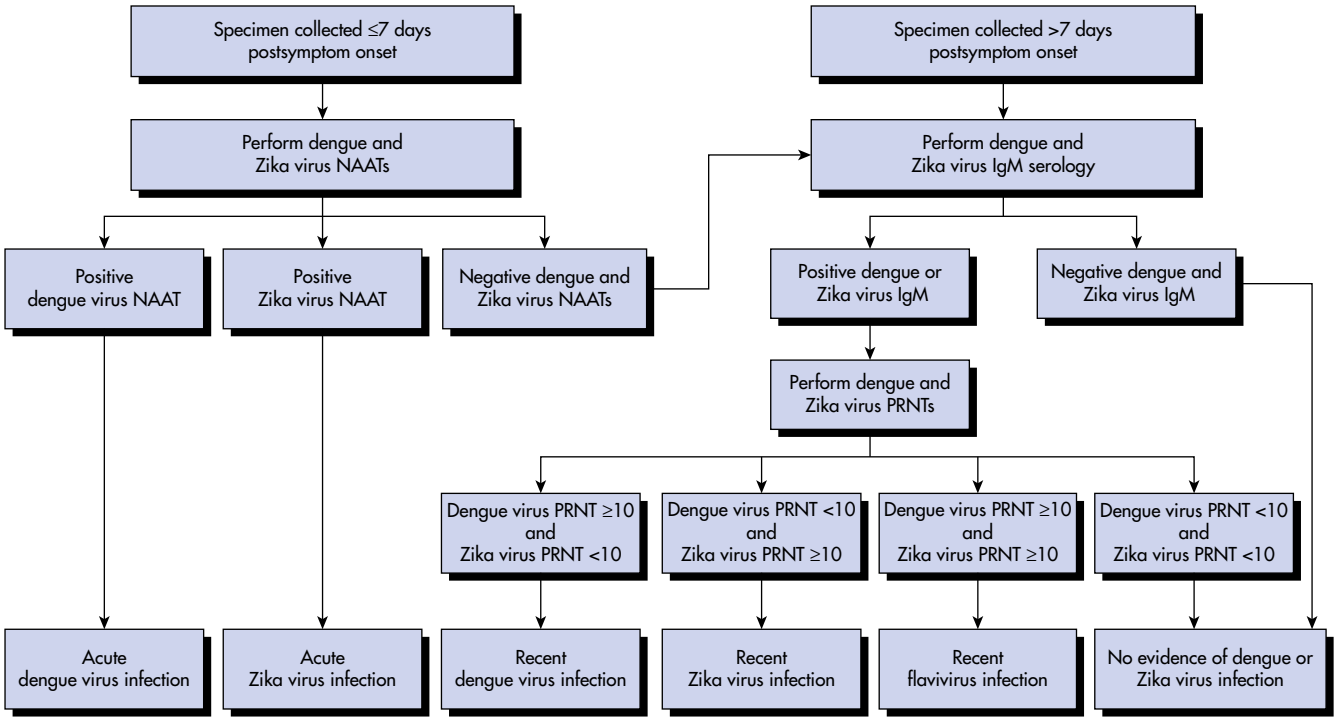

FIG. E3 Dengue and Zika virus testing recommendations for nonpregnant persons with a clinically compatible illness and risk for infection with both viruses. Specimen and test selection: Dengue and Zika virus NAATs, IgM antibody testing, and PRNTs should be performed on serum. Some NAATs also can be performed on plasma, whole blood, cerebrospinal fluid, or urine, and some antibody tests can be performed on plasma, whole blood, or cerebrospinal fluid. Laboratories may choose to perform dengue and Zika virus NAATs and IgM antibody testing simultaneously rather than sequentially, or to perform dengue virus nonstructural protein-1 testing instead of dengue virus NAAT. Indications to repeat assay(s): If the patient's illness has epidemiologic or clinical significance (e.g., first case of local transmission in area, new transmission mode, or unusual clinical syndrome), repeat a positive NAAT on newly extracted RNA from the same specimen. For indeterminate IgM antibody test results, repeat IgM antibody testing or perform PRNT on the same specimen. In areas where PRNTs are not performed, report the indeterminate results and request a second serum specimen for IgM antibody testing. Interpretation of results: Dengue and Zika virus IgM antibodies can be detected in serum for mos after infection. The specific timing of infection cannot be determined. Data on the epidemiology of viruses known to be circulating at the location of exposure and clinical findings should be considered when interpreting the results of serologic diagnostic testing. *IgM,* Immunoglobulin M; *NAAT,* nucleic acid amplification test; *PRNT,* plaque reduction neutralization test. (From Sharp TM et al: Dengue and Zika virus diagnostic testing for patients with a clinically compatible illness and risk for infection with both viruses, *MMWR Recomm Rep* 68[RR-1]:1-10, 2019.)

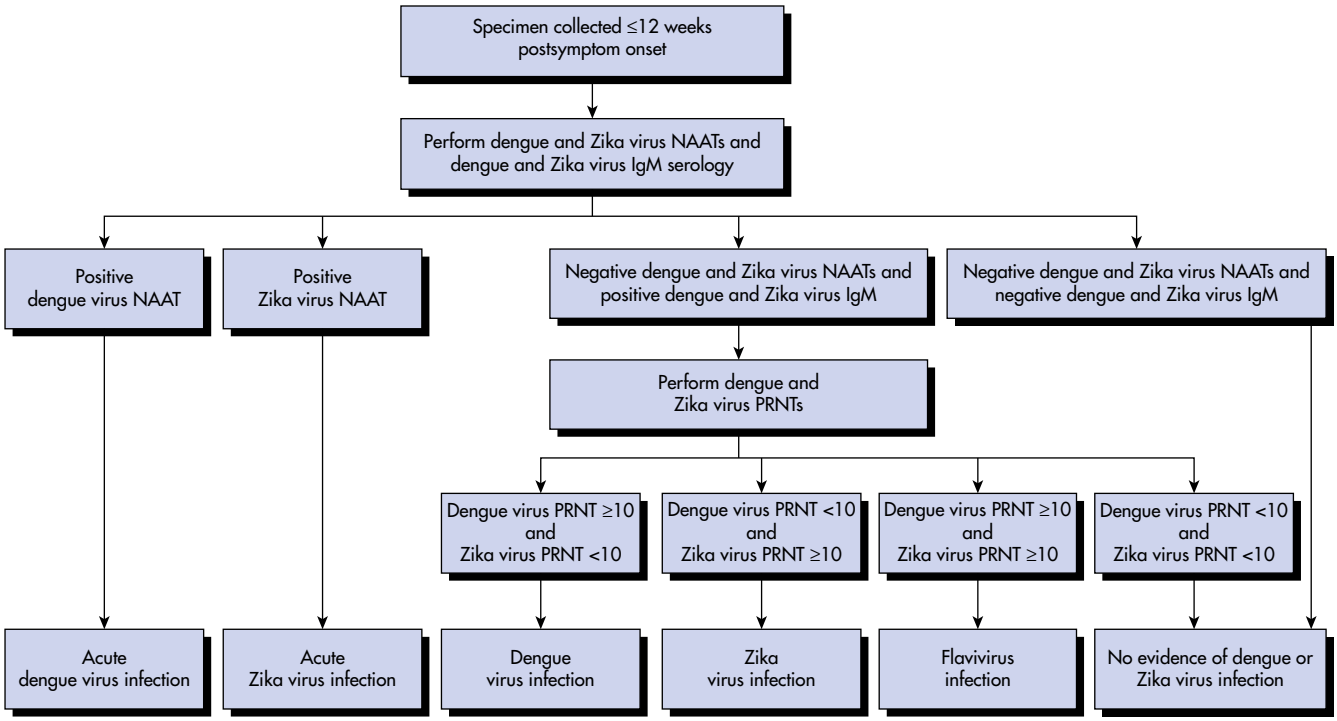

FIG. E4 Dengue and Zika virus testing recommendations for pregnant persons with a clinically compatible illness and risk for infection with both viruses. Specimen and test selection: Dengue and Zika virus NAATs, IgM antibody testing, and PRNTs should be performed on serum. Some NAATs also can be performed on plasma, whole blood, cerebrospinal fluid, or urine, and some antibody tests can be performed on plasma, whole blood, or cerebrospinal fluid. Dengue virus NAAT does not need to be performed on specimens collected >7 days after illness onset. Some laboratories may choose to perform dengue virus nonstructural protein-1 testing instead of dengue virus NAAT. Indications to repeat assay(s): If Zika virus NAAT is positive on a single specimen but IgM antibody tests are negative, repeat NAAT on newly extracted RNA from the same specimen. For indeterminate IgM antibody test results, repeat IgM antibody testing or perform PRNT on the same specimen. In areas where PRNTs are not performed, report the indeterminate results and request a second serum specimen for IgM antibody testing. Interpretation of results: Dengue and Zika virus IgM antibodies can be detected in serum for months after infection. The specific timing of infection cannot be determined. Data on the epidemiology of viruses known to be circulating at the location of exposure and clinical findings should be considered when interpreting the results of serologic diagnostic testing. *IgM,* Immunoglobulin M; *NAAT,* nucleic acid amplification test; *PRNT,* plaque reduction neutralization test. (From Sharp TM et al: Dengue and Zika virus diagnostic testing for patients with a clinically compatible illness and risk for infection with both viruses, *MMWR Recomm Rep* 68[RR-1]:1-10, 2019.)

Dependent Personality Disorder

BASIC INFORMATION

DEFINITION

Dependent personality disorder (DPD) is characterized by a pervasive and excessive need to be taken care of that leads to submissive and clinging behavior and fears of separation. DPD begins by early adulthood and causes significant distress or impairment in multiple domains of functioning. Individuals must meet five or more of the following criteria, each of which should be enduring and pervasive across contexts:

1. Difficulty making routine decisions without an excessive amount of advice and reassurance from others
2. Need others to assume responsibility for most major areas of their lives
3. Difficulty expressing disagreement with others because of fear of loss of support or approval
4. Difficulty initiating or completing projects on own because of a lack of self-confidence in abilities rather than lack of motivation or energy
5. Excessive attempts to obtain nurturance and support from others
6. Feeling uncomfortable or helpless when alone because of exaggerated fears of being unable to care for self
7. Urgently seeking another relationship when a close relationship ends
8. Unrealistically preoccupied with being left to take care of self

SYNONYMS

None

ICD-10CM CODE	
F60.7	Dependent personality disorder
DSM-5 CODE	
301.6	Dependent personality disorder

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 0.5% in general population. Dependent traits, as opposed to the disorder itself, are among the most frequently reported in outpatient mental health clinics.

PREDOMINANT SEX: Female (2:1) in clinical settings. There is concern about under-diagnosis in men.

CLINICAL PRESENTATION

- Early onset and chronic course. Impairment may be apparent only on close inspection.
- On interview, will defer excessively to partner or parent.
- Indecision in routine decisions.
- Depend on a parent or spouse to decide where they should live, work, and recreate and who they should befriend.
- Need for others to function for them goes beyond age-appropriate and situation-appropriate requests for assistance.
- Will agree with objectionable opinions, submit to unreasonable requests, and not express appropriate anger or disappointment for fear of alienating the person without whom they believe they cannot function.
- Convinced that they are not capable of independent function and present themselves as inept.
- Often do not develop independent living skills, perpetuating their dependency.
- Social relations tend to be limited to the few people on whom the person depends.

ETIOLOGY

Chronic physical illness or separation anxiety disorder may predispose for DPD.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dependency and personality changes arising as a consequence of another psychiatric disorder.
- Dependency arising as a consequence of a general medical condition.
- Most common comorbid psychiatric conditions are social anxiety disorder, panic disorder, agoraphobia, obsessive-compulsive disorder, major depressive disorder, and other personality disorders.
- Most common comorbid personality disorders are histrionic, avoidant, and borderline. Each of these disorders is characterized by dependent features. DPD is distinguished by its predominantly submissive, reactive, and clinging behavior.

WORKUP

- History: Collateral information is essential to establishing the presence of longstanding interpersonal pattern in multiple domains of the patient's life
- Physical examination
- Mental status examination

LABORATORY TESTS

Tests necessary to rule out medical causes of personality changes

IMAGING STUDIES

Tests necessary to rule out medical causes of personality changes

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cognitive-behavioral psychotherapy to diminish and better contain anxiety and to help patients develop sense of self as competent and learn requisite assertiveness skills.
- Psychodynamic psychotherapy to help develop improved self-concept and interpersonal functioning.
- Guidelines for general management of the patient with DPD:
  1. General strategy is to provide reassurance and allay fear of abandonment.
  2. Schedule frequent visits that occur regularly, regardless of how ill the patient feels (i.e., noncontingent care).
  3. Establish firm and realistic limits to availability as early as possible in treatment.
  4. Enlist other members of health care team for support.
  5. Encourage patient to develop additional "outside" support systems.

ACUTE GENERAL Rx

Benzodiazepines are used to control highly anxious states, although caution is warranted with regard to habituation and abuse potential in those with a dependent personality.

CHRONIC Rx

Selective serotonin reuptake inhibitors (SSRIs) and selective serotonin-norepinephrine reuptake inhibitors (SNRIs) for comorbid depression, social phobia, agoraphobia, and other anxiety disorders

COMPLEMENTARY & ALTERNATIVE MEDICINE

No evidence of efficacy in DPD

DISPOSITION

- Chronic course; severity is variable.
- At increased risk for major depression, social phobia, agoraphobia, and other anxiety disorders.
- Patients with DPD are at risk of victimization by partners. They are also at risk of suicidal or violent behavior if their relationships are threatened.

REFERRAL

- If pharmacotherapy or psychotherapy is indicated
- If patient's functioning is impaired

PEARLS & CONSIDERATIONS

COMMENTS

- Patients with DPD fear that a medical illness will lead to abandonment by others.
- This fear of simultaneous helplessness and abandonment intensifies neediness and may lead to dramatic demands for urgent medical attention.
- When physicians do not respond as wanted, angry outbursts may ensue.
- Medical care can also become a means by which dependency needs are met. As a result, some of these patients may unconsciously or consciously exaggerate their other illnesses (e.g., have primary gain from being sick). They may become high utilizers of health care.
- Physicians often react to the extreme neediness with avoidance or over-engagement, leading to burnout.

BASIC INFORMATION

DEFINITION

Major depression is an episodic, frequently recurring syndrome. The diagnosis requires that five of nine criteria be present for 2 wk. One of these nine criteria must be either a persistent depressed mood or pervasive anhedonia (loss of interest or pleasure in all, or almost all, usual interests or activities). Other symptoms include sleep disturbance (insomnia or hypersomnia), appetite loss/gain or weight loss/gain, fatigue, psychomotor retardation or agitation, difficulty concentrating or indecisiveness, feelings of guilt or worthlessness, and recurrent thoughts of death or suicidal ideation.

SYNONYMS

Unipolar affective disorder
Clinical depression
Melancholia
Manic-depressive illness, depressed type
Depressive episode

Codes depend on whether the episode is single or recurrent, and also on clinical severity.

ICD-10CM CODES

F32.9	Depressive episode, unspecified
F33.0	Recurrent depressive episode, current episode mild
F33.1	Recurrent depressive disorder, current episode moderate
F33.2	Recurrent depressive disorder, current episode severe without psychotic symptoms
F33.3	Recurrent depressive disorder, current episode severe with psychotic symptoms
F33.4	Recurrent depressive disorder, currently in remission
F33.9	Recurrent depressive disorder, unspecified

DSM-5 CODES

296.21	Single episode
296.22	Single episode, moderate
296.23	Single episode, severe
296.24	Single episode, with psychotic features
296.31	Recurrent, mild
296.32	Recurrent, moderate
296.33	Recurrent severe
296.34	Recurrent, with psychotic features

EPIDEMIOLOGY & DEMOGRAPHICS

LIFETIME RISK (IN U.S.): 10% of men, 20% of women

PREVALENCE (IN U.S.): Point prevalence in a community sample is 3% of men, 4.5% to 9.3% of women, and 1% of children. Prevalence of 20% to 40% in patients with comorbid medical conditions.

PREDOMINANT SEX: Female/male ratio 2:1

PREDOMINANT AGE: 25 to 44 yr; 5% of adolescents

PEAK INCIDENCE: 30 to 40 yr; 13% of postpartum women

GENETICS:

- Clear evidence of familial predominance.
- Prevalence is 2 to 3 times greater among first-degree relatives.
- Concordance among monozygotic twins approximately 50%.
- Several studies have documented associations between various genes and increased risk for major depressive disorder (MDD), but there remains no established pattern of inheritance.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical evaluation facilitated by organizing the major symptoms into four hallmarks: (1) Depressed mood, (2) anhedonia, (3) physical symptoms (sleep disturbance, appetite problem, fatigue, psychomotor changes), and (4) psychological symptoms (difficulty concentrating or indecisiveness, guilt or worthlessness, and suicidal ideation).
- A stressful life event, typically a serious loss, may trigger a depressive episode. DSM-5 recommends that clinical judgment be used to determine if depression in the context of a loss should be diagnosed as a major depressive episode.
- Patients often present with somatic complaints such as pain, fatigue, insomnia, dizziness, headache, or gastrointestinal problems. Somatic complaints may be reported more frequently among certain ethnic groups than depressed mood, increasing risk for underdetection in these groups.
- Comorbid psychiatric disorders are often present. Anxiety disorders are the most common comorbid conditions.
- May be associated with mood-congruent delusional thinking (paranoid and melancholic themes).
- May be associated with active or passive suicidal ideation.
- Serious misconduct may appear in adolescents.
- May be underdiagnosed in elderly patients, with signs and symptoms attributed to normal aging.
- May be underdiagnosed in medically ill patients, with signs and symptoms attributed to medical illness or considered appropriate reaction to medical condition.

ETIOLOGY

- A heterogeneous group of disorders probably arising from various etiologies.
- Genetic and environmental experiences, and their interaction, each contribute.
- Significant psychosocial stressors, including loss and history of childhood abuse or adversity, often trigger depression, particularly for first episodes.
- Numerous biologic correlates have been identified, though none is considered causative or diagnostic. Genes that influence the production and reuptake of serotonin, norepinephrine, dopamine, and glutamate, as well as nerve cell growth in brain regions underlying memory and emotional processing, are of greatest interest. Abnormalities in brain regions underlying executive functioning, emotion regulation, and reward processing, as well as irregularities in functional connectivity have been identified. Irregularities in cortisol responding and inflammation also may play a role.
- Cognitive risk factors include a pessimistic style of explaining negative events, a tendency to ruminate, and biases in processing emotional information and events.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anxiety disorders (e.g., social phobia, posttraumatic stress disorder [PTSD], obsessive compulsive disorder), substance abuse, and personality disorders often present with depressive symptoms.
- Important to determine if a depressive episode is part of major depression or part of bipolar disorder.
- Important to distinguish from adjustment disorder. Depression in the context of a stressful life event is diagnosed as major depressive disorder if the symptom criteria are met and adjustment disorder if the symptom criteria are not met. There is no evidence that medication is effective for adjustment disorder.
- Approximately 10% to 15% of depression caused by general medical illnesses, such as Alzheimer disease, Parkinson disease, stroke, end-stage renal failure, cardiac disease, HIV infection, and cancer.
- Some medical conditions present as depression (e.g., hypothyroidism, hyperthyroidism, pancreatic cancer, or neurosyphilis).
- Premenstrual dysphoric disorder.
- In elderly, depression often coexists with dementia.

WORKUP

- Careful medical history is required.
- Physical examination reveals no specific diagnostic signs of depression.
- Mental status examination.
- Self-report scales can assist in screening.
- Commonly used validated screening tools include the 15-item Geriatric Depression Scale in the elderly and the Patient Health Questionnaire (PHQ)-2 and PHQ-9. The PHQ-2 has a 97% sensitivity and 67% specificity in adults. If it is positive for depression, the PHQ-9 should be administered. The PHQ-9 has a 61% sensitivity and 94% specificity for depression in adults.

LABORATORY TESTS

- Research is underway to identify biomarkers that may be useful in diagnosis, but as of yet no laboratory studies are diagnostic.
- The following can assist in ruling out other confounding issues:
  1. Routine blood chemistry evaluation
  2. CBC with differential
  3. Thyroid function studies
  4. Vitamin B_{12} levels

IMAGING STUDIES

With unusual presentations (e.g., associated with new-onset severe headache, focal neurologic signs, a cognitive or sensory disturbance), the following may be performed:

- Electroencephalogram (EEG) (diffuse slowing indicates metabolic encephalopathy)
- Anatomic brain imaging (CT scan or MRI)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Good evidence that cognitive-behavioral therapy is as effective as antidepressant medication in achieving significant reduction or remission (Table 1).
- Problem solving and interpersonal psychotherapies are comparably efficacious.
- "New wave" cognitive-behavioral therapies (e.g., acceptance and commitment therapy, mindfulness-based cognitive-behavioral therapy [CBT]) have demonstrated efficacy in numerous studies. It is unclear as of yet whether new-wave versus traditional behavioral therapies differ in mechanisms of action. Individuals not responding adequately to traditional behavioral therapies may benefit.
- Growing evidence indicates that Internet-based CBT and brief therapy interventions integrated into primary care to expand access to therapy are efficacious, with some studies finding comparable efficacy to standard length interventions, but further research is needed.
- By 12 wk or earlier, psychotherapy and medication approaches are equally effective.
- Augmentation of standard depression treatment with CBT to address insomnia (CBT-I) was found to significantly improve response rates.
- Official treatment guidelines recommend that medication be used as the first-line treatment for patients with severe depression, although some studies have found equal efficacy of medication and psychotherapy in the treatment of severe depression.
- Evidence, although mixed, indicates that combined psychotherapy and medication may be more effective than either treatment alone. Various types of evidence-based psychotherapy or augmentation with psychotherapy, including CBT and mindfulness-based behavioral therapy, appear to reduce the risk for future recurrences compared to medication alone in some but not all studies, particularly when medication is discontinued after symptomatic remission.
- Factors, including history of childhood maltreatment, presence of precipitant stressful life events, family psychiatric history, the presence of anhedonia, and depression severity, may affect treatment response and risk of recurrence. Numerous genetic and neurobiologic variables that predict treatment response have been identified, particularly in combination with one another or with clinical characteristics. However, as of yet there are no universally accepted markers that can aid clinicians in matching individuals to particular medications or interventions.

ACUTE GENERAL Rx

- Concurrent medical or psychiatric illnesses, history of prior response, cost, patient preference, and side effects should be considered when selecting initial treatment.
- Antidepressants are helpful in approximately 60% to 70% of cases, though sustained remission rates are lower.
- Selective serotonin reuptake inhibitors (SSRIs) generally are first line. According to the Sequenced Treatment Alternatives to Relieve Depression (STAR-D) trial, approximately 30% achieve remission with the first prescribed medication after 3 mo of treatment. Another 25% to 30% respond to treatment but do not achieve remission. Treatment-refractory patients should be switched to another SSRI or to another class of medication, offered adjunctive medication such as bupropion, or referred for evidence-based counseling. Approximately 25% more patients will achieve remission with this secondary intervention.
- Response to antidepressants for many patients is seen as early as 2 wk, and among patients showing little to no response, the odds of later response decrease the longer patients remain unimproved. Conversely, rapid response to treatment predicted improved outcomes in multiple studies.
- To date no benefit of combining antidepressants as first-line treatment. Also no clear advantage has been identified for switching medications within vs. across different classes, or to switching vs. augmentation. The Veterans Affairs (VA) Augmentation and Switching Treatments for Improving Depression Outcomes (VAST-D) trial found that switching to the antipsychotic aripiprazole resulted in statistically significant, though modest, improvement in remission rates compared with switching or augmenting with an antidepressant, although greater side effects resulted. More research is needed.
- Therapy should be continued for 4 to 9 mo after the full remission of symptoms.
- Electroconvulsive therapy is the most effective means available for the treatment of severe, refractory depression. Transcranial magnetic stimulation has also shown evidence of efficacy though the magnitude of effects is more variable. To date electroconvulsive therapy has shown superior efficacy; research is under way to investigate mechanisms to increase the efficacy of transcranial magnetic stimulation (TMS).
- Antipsychotic medication should be added for psychotic depression. Antipsychotic medication has also been shown to be helpful in augmenting antidepressants for nonpsychotic depression, and it may be beneficial for individuals with mixed features, although more research is needed.
- Ketamine IV has been found to be rapidly effective in treatment-resistant and suicidal depression. Recently intranasal esketamine (Spravato) has been approved for use in treatment-resistant depression. Further research is needed to determine whether positive effects are maintained, because effectiveness appears to fade without repeated use.

CHRONIC Rx

Long-term treatment, in some cases lifelong, is recommended for multiple depressive episodes, an episode duration longer than 2 yr, a severe episode or significant suicidality, or a strong family history of severe depression or bipolar disorder.

DISPOSITION

- Major depression is often a relapsing and remitting illness.
- Physical symptoms may predict a favorable response to biologic intervention in some but not all studies.
- Additional episodes experienced by >50% after one episode, with each additional episode linked to increased risk for subsequent episodes.
- Without treatment, episodes last an average of 6 to 12 mo; risk of recurrence higher without treatment.
- For many depressed individuals, subthreshold residual symptoms are present between episodes and define the majority of an individual's course of depression. Such symptoms may lead to impairment and warrant prolonged treatment.
- Anxious distress, as defined by the DSM-5 specifier, was found in one recent study to predict greater clinical severity and functional impairment, above and beyond comorbid anxiety disorder diagnoses.

TABLE 1 Treatments of Depression

Name of Psychotherapy	Approach
Cognitive psychotherapy	Identify and correct negativistic patterns of thinking.
Interpersonal psychotherapy	Identify and work through role transitions or interpersonal losses, conflicts, or deficits.
Problem-solving therapy	Identify and prioritize situational problems; plan and implement strategies to deal with top-priority problems.
Psychodynamic psychotherapy	Use therapeutic relationship to maximize use of the healthiest defense mechanisms and coping strategies.

From Goldman L et al: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.

REFERRAL

- If treatment refractory
- If patient suicidal or psychotic
- For suspected bipolar depression

PEARLS & CONSIDERATIONS

COMMENTS

- All threats of suicide should be taken very seriously. Clinicians can use the mnemonic SAL: Is the method specific? Is it available? Is it lethal?
- Rule out bipolar affective disorder before initiating antidepressant medication. Screening scales for bipolar disorder can be helpful in primary care settings to identify patients at increased risk for bipolar disorder, although unclear benefit in mental health settings.
- Many patients and families reluctant to acknowledge depression because of stigma.
- A two-question screener is as effective as longer instruments. A positive answer to either question warrants a full assessment.
  1. Over the past 2 weeks, have you ever felt down, depressed, or hopeless?
  2. Over the past 2 weeks, have you felt little interest or pleasure in doing things?
- Depression screening programs without treatment programs are unlikely to improve depression outcomes.
- Strict monitoring of patients who initiate antidepressant therapy is necessary both for safety and to ensure optimal treatment. Use of self-report scales to measure symptom severity is helpful in monitoring outcome and may result in improved outcomes.
- St. John's wort *(Hypericum perforatum)* is sold as a dietary supplement in the United States and is used for depression in the community. It is not consistently effective and should not be used in combination with antidepressants given the possibility of severe serotonin-related side effects.

De Quervain Tenosynovitis PTG

BASIC INFORMATION

DEFINITION

De Quervain tenosynovitis is a tenosynovitis of the wrist's first dorsal extensor compartment, containing the abductor pollicis longus (APL) and extensor pollicis brevis (EPB) tendons.

SYNONYMS

Stenosing tenosynovitis of the radial styloid process
Stenosing tenovaginitis of the first dorsal compartment
Radial styloid tenosynovitis
Tenosynovitis of radial styloid
De Quervain disease
De Quervain stenosing tenosynovitis
De Quervain tendinitis
Washerwoman sprain/strain
Tendinosis
Styloid tenovaginitis

ICD-10CM CODES

M65.4	Radial styloid tenosynovitis [de Quervain]
M65.9	Synovitis and tenosynovitis, unspecified
M65.849	Other synovitis and tenosynovitis, unspecified hand

EPIDEMIOLOGY & DEMOGRAPHICS

- More common in women than in men (10:1)
- Usually occurs between the ages of 30 and 50
- May be associated with systemic inflammatory diseases (rheumatoid arthritis)
- Often seen in new mothers or day care providers due to holding the babies with an extended and abducted thumb
- Seen more frequently in certain occupations involving repetitive wrist motion

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Pain over the styloid process of the radius with grasping and resisted thumb abduction
- Tenderness with palpation over the radial styloid and first dorsal extensor compartment
- Pain may radiate up to the volar aspect of the wrist or to the thumb
- Swelling on the radial styloid
- Positive Finkelstein test (Fig. E1)
- Crepitance
- Rarely, numbness of dorsum of thumb
- Absence of local heat on examination

ETIOLOGY

- Repetitive use or overuse of the hand and thumb involving pinching with the thumb while moving wrist in radial and ulnar directions (e.g., typing, writing, nailing, golfing, fly-fishing)
- Acute trauma to the first dorsal extensor compartment
- Anatomic abnormality or variation
- Increased volume states or hormonal causes, such as occurring during pregnancy

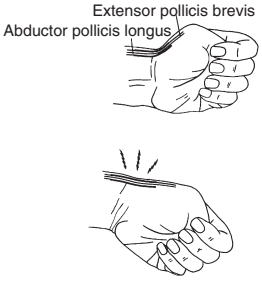

FIG. E1 Finkelstein test is positive in de Quervain stenosing synovitis. Ulnar flexion of the wrist produces pain over the dorsal compartment containing the extensor pollicis brevis and abductor pollicis longus.

DIAGNOSIS

- The diagnosis of de Quervain tenosynovitis is based on the clinical triad of:
  1. Tenderness over the radial styloid
  2. Pain over the first dorsal extensor compartment on resisted thumb abduction or extension
  3. Pain on ulnar movement of the wrist with the thumb adducted and flexed (Finkelstein test; see Fig. E1)
- Consideration can be given to injecting 1.5 ml of 1% Xylocaine into the tenosynovial sac, and if all three physical signs resolve, the diagnosis is confirmed, allowing for differentiation from carpometacarpal (CMC) osteoarthritis (OA)
- Finkelstein maneuver can also be present in first CMC joint OA

DIFFERENTIAL DIAGNOSIS

- Carpal tunnel syndrome
- Radiocarpal arthritis, thumb carpometacarpal arthritis
- Gout
- Infiltrative tenosynovitis
- Compression neuropathy (e.g., superficial branch of the radial nerve "bracelet syndrome")
- Ganglion cysts
- Infection (e.g., tuberculosis, bacterial)
- Radial styloid fracture

IMAGING STUDIES

- Imaging of the wrist and thumb is not necessary unless fracture or arthritis is suspected.
- Radiographs (three views) of the wrist should be obtained if fracture is suspected.
- Magnetic resonance imaging is helpful in selected cases. Tenosynovitis is seen as fluid signal on T2-weighted sequences within the tendon sheath as well as surrounding soft tissue edema with loss of adjacent fat planes (Fig. E2). Tendinosis represents a more advanced overuse injury manifested as an

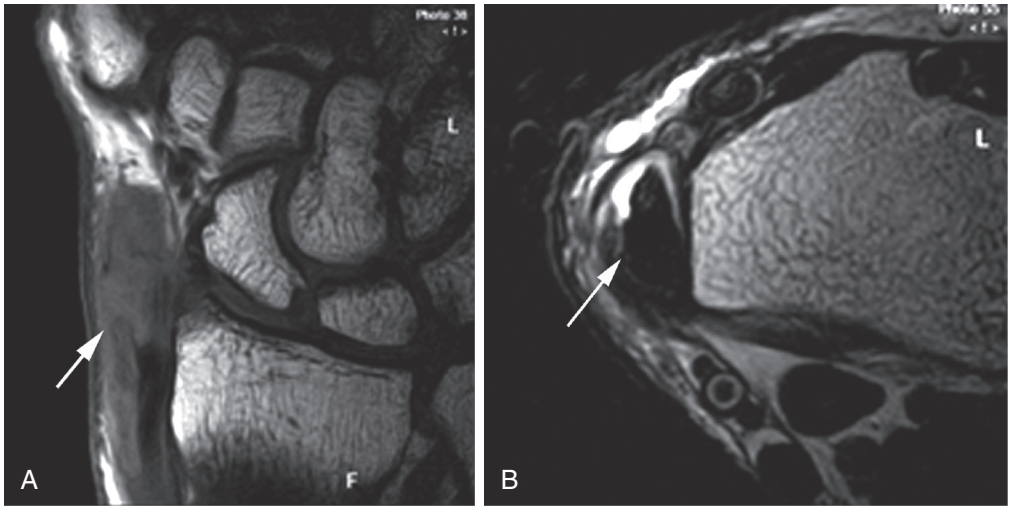

FIG. E2 De Quervain tenosynovitis. Coronal **(A)** and axial **(B)** T1-weighted MR images demonstrate thickening and synovial enlarged sheath of the first extensor compartment tendons *(arrows)*. (From Pope TL, et al.: *Musculoskeletal imaging*, ed 2, Philadelphia, 2015, Elsevier.)

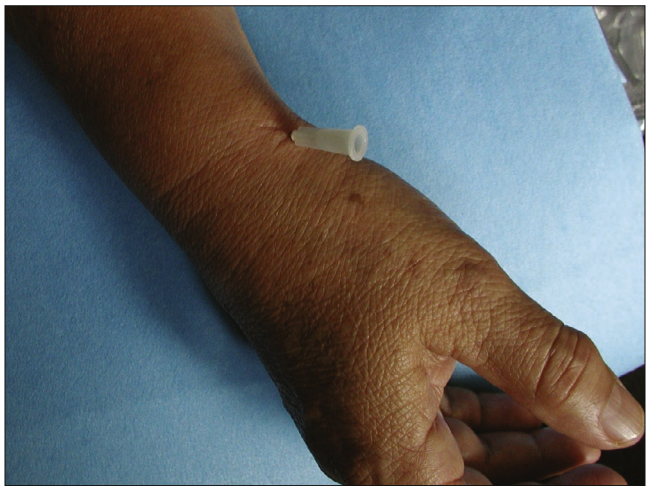

FIG. E3 Injection for right de Quervain tenosynovitis. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

enlarged tendon with internal increased signal intensity. Increased signal intensity within the tendon substance as an isolated sign is unreliable for de Quervain disease. Stenosing tenosynovitis appears as an intermediate–signal-intensity ring surrounding the tendons in both T1- and T2-weighted images.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoiding repetitive movements of hand or thumb
- Thumb spica splint
- Icing (4 to 6 times a day for 15 min)
- Physiotherapy

ACUTE GENERAL Rx

- Corticosteroid injection using 20 to 40 mg triamcinolone acetonide and 1% Xylocaine (Fig. E3) is often diagnostic and therapeutic
- Oral NSAIDs (ibuprofen 800 mg tid or naproxen 500 mg bid)
- Topical NSAIDs (Voltaren gel)

CHRONIC Rx

- Once signs of active inflammation have resolved after 3 to 4 wk, gentle stretching exercises involving abductor and extensor tendons usually help recovery.
- Maximum trial of three corticosteroid injections at minimum 3-mo intervals (one every 3 mo or more).
- Surgical intervention is generally reserved for those patients not responding to above treatments.
- Surgery includes first dorsal extensor compartment and subcompartment releases with or without tenosynovectomy.

DISPOSITION

- ~82% of patients have initial relief of symptoms with corticosteroid injection.
- ~52% of patients remain symptom-free at 12 mo after corticosteroid injection.
- ~73% of patients report successful results after two corticosteroid injections.
- Rarely, steroid injection can lead to infection, skin hypopigmentation, fat atrophy, and tendon rupture.
- Diabetics may experience mild temporary hyperglycemia after corticosteroid injection.
- Accidental injection of the corticosteroid in the subcutaneous tissue instead of the sheath of the extensor compartment should be avoided to prevent fat and dermal atrophy.
- If left untreated, can lead to fibrosis and decrease in mobility (stenosing tenosynovitis).
- Surgical resolution of symptoms achieved in 90% of referred cases.
- Complications of surgery include:
  1. Superficial branch of the radial nerve injury
  2. Paresthesia (10%)
  3. Neuroma formation
  4. Hypertrophic or painful scar
  5. Chronic regional pain syndrome
- Recovery rates with early treatment are at least 80% after 6 wk but <40% after 4 yr.

PEARLS & CONSIDERATIONS

- Steroid injection is generally recommended after failure of 2 to 6 wk of conservative treatment.
- Pain relief usually noted within 48 hours, with patient becoming asymptomatic 1 to 2 wk after corticosteroid injection.
- If no improvement 6 wk after second corticosteroid injection, consider referral to an orthopedic hand surgeon.
- Condition can recur if triggering activity continues.

Dermatitis Herpetiformis ALG

BASIC INFORMATION

DEFINITION

Dermatitis herpetiformis (DH) is an autoimmune blistering disease that is considered to be a cutaneous manifestation of celiac disease (CD). It is associated with gluten-sensitive enteropathy in nearly all cases, although only 20% of patients have gastrointestinal symptoms. 15% to 25% of patients with CD will have DH.

SYNONYMS

DH
Duhring disease

ICD-10CM CODE
L13.0 Dermatitis herpetiformis

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.): 11 cases per 100,000 persons per yr; prevalence for CD is one in 133 adults
PREDOMINANT SEX: Male predominance (2:1); however, female predominance in children
PREDOMINANT AGE: Fourth decade of life, but can occur at any age
PREDOMINANT RACE: Most common in Caucasians of Northern European ancestry
GENETICS: Both CD and DH have a strong genetic component. 10% to 15% of patients with DH have a first-degree relative with either DH or CD. Specific HLA genes (involved in processing gliadin antigen in genetically susceptible individuals) have also been shown to predispose to developing DH (HLA-DQ2 in 90%, DQ8 in the remaining 10%). However, less than 50% of genetic predisposition is attributed to HLA genes.

PHYSICAL FINDINGS & CLINICIAL PRESENTATION

- Classically, the lesions of DH are small, grouped, "herpetiform" vesicles that are distributed symmetrically on extensor surfaces (elbows, knees [Fig. E1], scalp, back, and buttocks). However, due to intense pruritus and scratching, pinpoint erosions and excoriations in the above distribution are often the most prominent findings on examination, with intact vesicles rarely seen.
- Spontaneous improvement with cyclic exacerbations is common.
- Celiac-type enamel defects to permanent teeth, oral vesicles, or palmoplantar purpura have been reported as potential associated findings.

PATHOGENESIS

CD and DH are both autoimmune-mediated by immunoglobulin A (IgA) class autoantibodies. Dietary gluten is central to the pathogenesis in both. In genetically predisposed individuals, it is hypothesized that the gluten by-product, gliadin, complexes with tissue transglutaminase (tTG) in the gut, binding as an antigen to HLA-DQ2 on T cells, creating an immune response that results in anti-tTG IgA antibodies (i.e., antiendomysial antibodies) in the blood. tTG cross-reacts with epidermal TG (eTG). The blood of CD patients with and without skin disease is found to have both skin and gut anti-TG IgA antibodies. Yet, it is thought that the high-affinity IgA against eTG form complexes that are responsible for DH. The deposition of IgA-eTG complexes in the papillary dermis triggers an immunologic cascade resulting in neutrophil recruitment and complement activation.

DIAGNOSIS

Physical examination and routine histopathology are often suggestive of DH; however, direct immunofluorescence (DIF) of a perilesional skin biopsy has pathognomonic findings and is the gold standard for diagnosis. Fig. 2 describes an approach to the patient with suspected dermatitis herpetiformis.

DIFFERENTIAL DIAGNOSIS

- Clinically and histologically, the differential diagnosis includes:
  1. Linear IgA dermatosis
  2. Bullous pemphigoid
  3. Bullous lupus

  These diagnoses can be differentiated by DIF on perilesional skin biopsy.
- Other clinical diagnoses to consider:
  1. Scabies (check for interdigital burrows and involvement of genitalia)
  2. Arthropod bite (papular urticaria over exposed areas)
  3. Eczematous dermatitis (ill-defined, weeping erythematous plaques)
  4. Herpes simplex or zoster infection (painful, not symmetric)
  5. Generalized pruritus (no blister history)

WORKUP AND LABORATORY TESTS

- Evaluation for gastrointestinal symptoms, family history of DH or CD, and pruritus should be sought in patients with suspected DH.
- **Lesional skin biopsy:** Will demonstrate a neutrophil-rich subepidermal bulla and rule out many conditions.
- **DIF of normal-appearing perilesional skin biopsy:** Will demonstrate pathognomonic IgA deposits localized to the dermal papillae and dermal-epidermal junction in a granular pattern.
- Serology (enzyme-linked immunosorbent assay [ELISA]) for IgA tissue transglutaminase, ELISA for IgA epidermal transglutaminase, if available, and indirect immunofluorescence for IgA endomysial antibodies (total IgA) can be used to aid in the diagnosis of DH in cases where the DIF is negative or equivocal, or for monitoring disease activity response to treatment. Although these circulating antibodies in the blood exist, there is a high false-positive rate for antitissue TG and for antiendomysial antibodies (one third of DH patients are negative for antiendomysial antibodies), and their absence does not exclude the diagnosis. Also, IgA-deficient DH patients may also have negative serologic results. Those with the presence of circulating antibodies will have a reduction in levels in response to treatment adherence.

TREATMENT

A gluten-free diet (GFD) and dapsone are considered first-line therapy and are often started in conjunction.

- GFD improves symptoms of both GI and skin disease, with GI responding quicker (skin responds after 2 mo). A retrospective study showed remission (2 yr without symptoms) in 12%.
- Dapsone results in improvement of skin manifestations within days but does not treat GI manifestations. Dapsone is typically tapered over time, while lifelong gluten avoidance is often necessary.
- One study demonstrated GFD alone was comparable to GFD plus dapsone in the treatment of DH; hence GFD is an essential component in the treatment of DH.

NONPHARMACOLOGIC THERAPY

- First line: GFD:
  1. Avoid barley, rye, wheat (can consume rice, corn, and oats).
  2. Consultation with a dietitian is recommended.
  3. Most patients need to follow diet indefinitely; however, cases of spontaneous remission have been reported.
- Second line: Elemental diet (controversial):
  1. Can consider elemental diet (avoidance of whole proteins) in those patients who do not adequately respond to a strict GFD; however, data are limited.

ACUTE GENERAL Rx

- First line: Dapsone:
  1. Initial dose 25 to 50 mg PO daily with gradual increase to an average maintenance dose of 0.5 to 1 mg/kg daily (often maintenance dose of 100 mg daily).
  2. Clinical monitoring weekly is recommended to optimize dose (optimal dose is when 1 to 2 new lesions/wk).
  3. Caution: Dapsone may produce hemolysis (especially if G6PD deficiency), agranulocytosis, methemoglobinemia, systemic drug hypersensitivity reaction (DRESS), and a peripheral neuropathy.
  4. Baseline labs: CBC, LFTs, G6PD levels. After the initiation of therapy, monitor CBC every wk ×1 mo, then every other wk ×2 mo, monthly ×3 mo, then every 3 to 4 mo. Monitor LFTs every 3 to 4 mo.
- Second-line alternatives:
  1. Sulfapyridine (500 to 1500 mg/day, compounded medication) or sulfasalazine (500 to 1000 mg bid) may be substituted in cases of dapsone intolerance or in the rare case that neuropathy develops.
  2. Case reports of efficacy using topical dapsone 5% twice daily in patients who do not tolerate oral dapsone; also report-

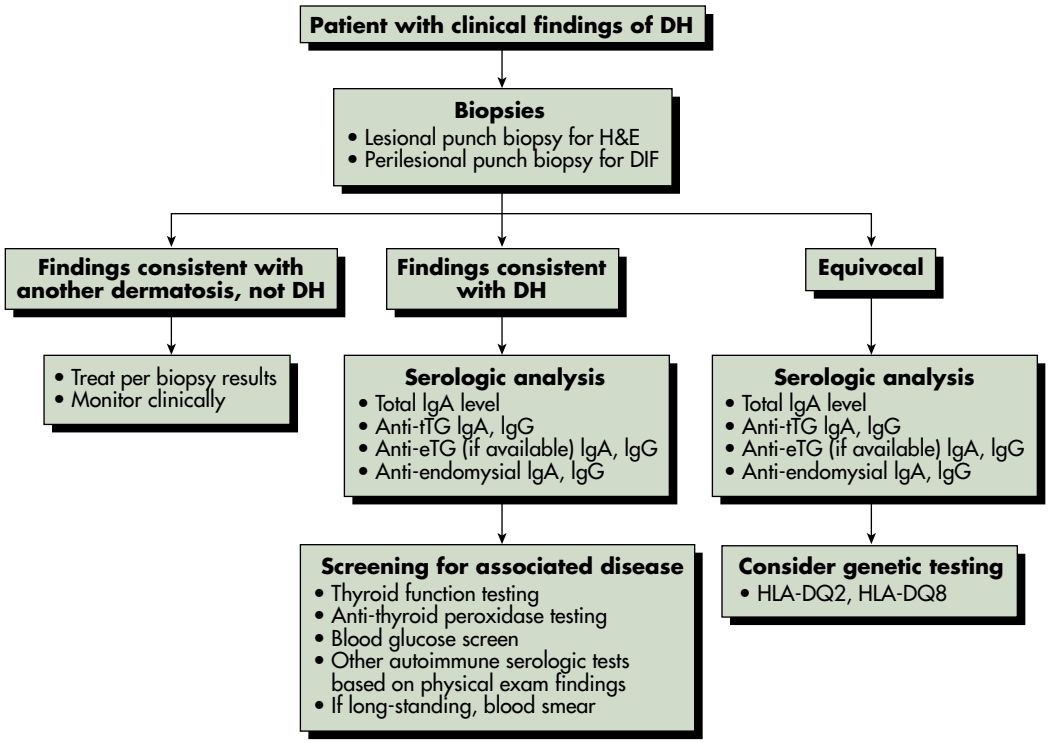

FIG. 2 Approach to the patient with suspected dermatitis herpetiformis. *DH,* Dermatitis herpetiformis; *DIF,* direct immunofluorescence; *eTG,* epidermal transglutaminase; *H&E,* hematoxylin and eosin; *HLA-DQ2,* histocompatibility locus antigen haplotype DQ2; *HLA-DQ8,* histocompatibility locus antigen haplotype DQ8; *Ig,* immunoglobulin; *tIG,* tetanus immune globulin. (From Bolotin D, Petronic-Rosic V: Dermatitis herpetiformis: part II. Diagnosis, management, and prognosis, *J Am Acad Dermatol* 64:1027-1033, 2011.)

ed to be efficacious as an adjuvant to oral dapsone.
3. Uncontrolled studies and case reports have suggested efficacy with tetracyclines, nicotinamide, cyclosporine, colchicine, and heparin.

- Symptomatic relief for pruritus:
1. Potent and superpotent topical corticosteroids (atrophy with prolonged use, limit to 14 days per mo), nonsedating antihistamines twice daily, sedating antihistamines at bedtime, mentholated lotion

CHRONIC Rx

- As DH is considered to represent the cutaneous manifestations of CD, lifelong avoidance of gluten is typically recommended. Information about educational resources, such as national and local support groups, should be provided (www.celiac.org).
- Patients with DH and CD have an increased risk of developing Hashimoto thyroiditis (50% with thyroid disease), non-Hodgkin lymphoma, and GI lymphomas. An increased incidence of other autoimmune disorders (type 1 diabetes mellitus, pernicious anemia, Addison disease, vitiligo, systemic lupus erythematosus, rheumatoid arthritis, and Sjögren syndrome) and osteoporosis have also been reported.
1. Screening for thyroid disease (TSH, antithyroid peroxidase antibody titers) is typically recommended.
2. Screening for autoimmune connective tissue diseases should be considered if there are suspicious signs or symptoms.
3. Routine screening for GI lymphomas is controversial.

REFERRAL

- Dermatologist for skin biopsy and management of cutaneous disease
- Gastroenterologist for evaluation of CD
- Nutritionist to educate patients about gluten-free diet
- National support groups (www.celiac.org) and local support groups

PEARLS & CONSIDERATIONS

- Classic areas involved are those that are exposed if in a "fetal position."
- Lesions may be worsened by iodides and certain NSAIDs; systemic steroids ineffective.
- Location of biopsies is IMPORTANT: False-negative DIF can result if biopsies are taken from lesional skin (should be taken from normal-appearing skin adjacent to lesion) as diagnostic IgA deposits are usually destroyed by the blistering process.
- GFD results in reduced IgA in skin on DIF (with eventual disappearance) and reduced antiendomysial antibodies in the blood. Hence, serologies (e.g., antiendomysial antibodies) can be used to monitor degree of compliance to dietary gluten restriction.
- Some studies have suggested a possible protective effect of GFD against intestinal lymphoma. First-degree relatives do not appear to be at increased risk for GI or systemic lymphomas in the absence of DH or CD.

Diabetes Insipidus (ALG) (PTG)

BASIC INFORMATION

DEFINITION

Diabetes insipidus (DI) is a disorder involving insufficient production and secretion of arginine vasopressin (AVP), also known as antidiuretic hormone (ADH). Decreased sensitivity to AVP also results in polyuria of hypotonic urine. The former condition is known as central DI (CDI), and the latter is referred to as nephrogenic DI (NDI). The main presentation of DI is hypernatremia from the loss of large amounts of hypotonic urine.

ICD-10CM CODE
E23.2 Diabetes insipidus

EPIDEMIOLOGY & DEMOGRAPHICS

GENETICS: The annual incidence of DI is 3 in 100,000. CDI usually manifests between the ages of 10 and 20 yr, with no sex predilection. NDI can begin at any age. During childhood, the most common cause is attributed to a vasopressin receptor-2 mutation, which is an X-linked mutation in the AVP receptor-2 gene. Less common hereditary forms of nephrogenic DI involve mutations in the aquaporin-2 water channel gene that affect the AVP-sensitive water channel and that may be autosomal dominant or recessive. The most common cause of CDI is idiopathic and likely related to autoimmune disorders.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The physical findings and clinical manifestations are generally not evident until AVP secretion capacity is <20% of normal.

- Unexplained nocturia (often the first manifestation of DI)
- Polyuria
- Polydipsia
- Neurologic manifestations (seizures, headaches, visual field defects)
- Symptoms of dehydration

ETIOLOGY

Central DI

- Idiopathic: Most common cause of CDI (destruction of AVP-secreting cells) likely due to an autoimmune mechanism.
- Hereditary (familial neurohypophyseal): Multiple genetic causes have been identified. An autosomal dominant form affects neurophysin II, a carrier protein for vasopressin. Wolfram syndrome involves an autosomal recessive form of DI that may be accompanied by childhood-onset diabetes mellitus, optic atrophy, and deafness (DIDMOAD).
- Malignancy: Neoplasms of the brain or pituitary fossa. They may be primary, as with craniopharyngiomas, or secondary to metastatic diseases, such as leukemia, lymphoma, breast cancer, or lung cancer.
- Hypoxic encephalopathy.
- Infiltrative disease: Histiocytosis, sarcoidosis, granulomatosis with polyangiitis, or tuberculosis.
- Other: Intraventricular hemorrhage, aneurysms, meningitis, postencephalitis complication, multiple sclerosis, Guillain-Barré syndrome, IgG4-related disease, and lymphocytic hypophysitis.

Nephrogenic diabetes insipidus:

- Familial: X-linked (~90%), autosomal dominant and recessive (<10%)
- Toxic (drugs): Lithium via downregulation of aquaporin-2 water channel production. Other medications: Aminoglycosides, antivirals (foscarnet, didanosine), amphotericin B, demeclocycline, ifosfamide, and methoxyflurane
- Metabolic: Hypercalcemia and hypokalemia. Both conditions are reversible after correction of the respective metabolic abnormality
- Renal disorders: Medullary interstitial diseases resulting in hypoxia (e.g., sickle cell disease) and infiltration (e.g., sarcoidosis) lead to loss of the corticomedullary concentration gradient with inability to produce an appropriately concentrated urine
- Other: Urinary tract infection, Sjögren syndrome, pyelonephritis, nephronophthisis, polycystic disease, postobstructive, and low-protein diets (protein malnutrition), which prevents development of a maximal corticomedullary concentration gradient, with inability to produce an appropriately concentrated urine

Gestational DI due to a circulating vasopressinase.

- A third-trimester or early postpartum disorder of accelerated vasopressin degradation from elevated placental production and circulation of a cysteine aminopeptidase. Placental abruption or retained necrotic placenta may produce postpartum DI following release of large amounts of vasopressinase into the bloodstream. This disorder may occur after extensive tissue injury (e.g., large abscesses). Gestational DI demonstrates a salutary response to the administration of the synthetic AVP analogue, 1-desamino-8-D-arginine vasopressin (dDAVP), resistant to placental enzyme degradation.

TABLE E1 Differential Diagnosis of Nephrogenic Diabetes Insipidus

Hereditary causes	Aquaporin-2 mutations
	Arginine vasopressin receptor mutations
Drug-related causes	
V_2 -receptor antagonists	Lithium
	Demeclocycline
Antibiotic agents	Ofloxacin
	Rifampin
	Netilmicin
	Antifungal agent amphotericin B
Antiviral agents	
	Cidofovir
	Foscarnet
	Indinavir
	Tenofovir
Antineoplastic agents	
	Cyclophosphamide
	Ifosfamide
	Methotrexate
Other drugs	
	Radiocontrast agents
	Colchicine
	Ethanol
	Orlistat
Metabolic	Hypokalemia
Other conditions	Hypercalcemia
	Sjögren syndrome
	Sickle cell disease
	Release of urinary tract obstruction
	Amyloidosis
	Pregnancy

From Ronco C et al: *Critical care nephrology*, ed 3, Philadelphia, 2019, Elsevier.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diabetes mellitus, nephropathies
- Primary polydipsia, medications (e.g., chlorpromazine)
- Osmotic diuresis, including glucose, mannitol, anticholinergics
- Primary polydipsia and electrolyte disturbances

WORKUP

- The diagnostic workup is aimed at demonstrating polyuria due to an inability to appropriately concentrate urine and determine whether the polyuria results from decreased vasopressin availability or insensitivity to its action. This may be carried out by a water restriction test (Table E2) when the plasma sodium is <145 mmol/L or plasma osmolality is <295 mOsm/kg of water (Table E3):
  1. The diagnostic workup is aimed at demonstrating that polyuria is caused by an inability to concentrate urine and determining whether the problem results from reduced circulating vasopressin or insensitivity to this hormone. A water restriction test may be conducted if the plasma sodium is <145 mmol/L and plasma osmolality is <295 mOsm/kg of water (Table E3).
  2. After baseline measurement of body weight, vasopressin, plasma sodium, and urine and plasma osmolalities, the patient is deprived of fluids under medical supervision.
  3. Plasma and urine osmolalities are monitored every 2 hr.
  4. Test is generally terminated when plasma osmolality is >295 mOsm/kg of water or body weight decreases by >3.5% of baseline body weight.
  5. DI is confirmed if plasma osmolality is >295 mOsm/kg of water and urine osmolality is <500 mOsm/kg of water.

TABLE E2 Fluid Deprivation Test for the Diagnosis of Diabetes Insipidus

Procedure

1. Initiation of the deprivation period depends on the severity of the DI; in routine cases, the patient is made NPO after dinner. In patients with more severe polyuria and polydipsia, this interval may be not be tolerable. If this is the case, water deprivation should proceed in the early morning (e.g., 6:00 AM).
2. Obtain plasma and urine osmolalities, plasma electrolytes, and plasma AVP levels at the start of the test.
3. Measure urine volume and osmolality hourly or with each voided urine.
4. Stop the test when body weight decreases by ≥3%, orthostatic blood pressure changes appear, the urine osmolality plateaus (i.e., <10% change over two or three consecutive measurements), or the plasma sodium concentration increases to >145 mmol/L.
5. Obtain plasma and urine osmolalities, plasma electrolytes, and plasma AVP levels at the end of the test, when the plasma osmolality is elevated, preferably >300 mOsm/kg of water.
6. If plasma Na^+ <146 mmol/L or plasma osmolality <300 mOsm/kg of water when the test is stopped, then consider a short infusion of hypertonic saline (3% NaCl at a rate of 0.1 ml/kg/min for 1 to 2 hours) to reach these end points.
7. If hypertonic saline infusion is not required to achieve hyperosmolality, administer AVP (5 U) or desmopressin (dDAVP; 1 μg) subcutaneously and continue following urine osmolality and volume for an additional 2 hours.

Interpretation

1. An unequivocal urine concentration after AVP or dDAVP (>50% increase) indicates central diabetes insipidus (CDI); an unequivocal absence of urine concentration (<10%) strongly suggests nephrogenic DI (NDI) or primary polydipsia (PP).
2. Differentiating between NDI and PP, as well as cases in which the increase in urine osmolality after AVP or dDAVP administration is more equivocal (e.g., 10%-50%), is best done using the relation between plasma AVP levels and plasma osmolality obtained at the end of the dehydration period and/or hypertonic saline infusion and the relation between plasma AVP levels and urine osmolality determined under basal conditions.

From Skorecki K et al: *Brenner & Rector's the kidney*, ed 10, Philadelphia, 2016, Elsevier.

TABLE E3 Water Deprivation Test

Diagnosis	U_{Osm} with Water Deprivation (mOsm/kg of Water)	Plasma AVP after Dehydration	Increase in U_{Osm} with Exogenous AVP
Normal	>800	>2 pg/ml	Little or none
Complete central diabetes insipidus	<300	Undetectable	Substantial
Partial central diabetes insipidus	300-800	<1.5 pg/ml	>10% of U_{Osm} after water deprivation
Nephrogenic diabetes insipidus	<300-500	>5 pg/ml	Little or none
Primary polydipsia	>500	<5 pg/ml	Little or none

AVP, Arginine vasopressin.
Adapted from Lanese D, Teitelbaum I: Hypernatremia. In Jacobson HR et al [eds]: *The principles and practice of nephrology*, Philadelphia, 1998, Mosby.

6. To distinguish NDI from CDI, the change in urine osmolality is measured after a vasopressin dose of 5 units. A significant increase (>50%) in urine osmolality after administration of vasopressin is consistent with the diagnosis of CDI.
7. Copeptin is a surrogate of ADH and is cleaved from the C-terminal segment of the arginine vasopressin prohormone. A recent study in 2018 evaluated direct measurement of hypertonic saline-stimulated plasma copeptin and was found to be more accurate than the indirect water deprivation test.
8. A diagnostic algorithm for diabetes insipidus is displayed in Fig. E1.

LABORATORY TESTS

- Decreased urinary specific gravity (≤1.005).
- Baseline plasma osmolality >295 mOsm/kg of water suggests CDI. Levels <270 mOsm/kg of water favor compulsive water drinking.
- Hypernatremia, increased plasma osmolality, hypercalcemia, and hypokalemia from water-induced potassium losses.

IMAGING STUDIES

Pituitary MRI if CDI is confirmed

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient education regarding control of fluid balance, low-solute diet, and prevention of dehydration with adequate fluid intake or intravenous D_5W solution
- Daily weight

ACUTE GENERAL Rx

Therapy varies with degree and type of DI (Table E4). Initial therapy is directed toward alleviating nocturia with bedtime desmopressin followed by partial control of diuresis. Care must be given to avoid an abrupt onset of hyponatremia with potential cerebral edema by careful dDAVP titration.

- Central diabetes insipidus:
  1. Desmopressin (dDAVP): Intranasal route is preferred due to better bioavailability. First dose is 5 to 10 mcg intranasally or 0.1 to 0.2 mg by mouth at bedtime. Daytime dosing is dictated by the response to the evening dose. Typical maintenance doses are 10 to 20 mcg intranasally once or twice daily. The oral form has poor absorption from the gut with approximately 5% absorbed, with relative potency of just 5% to 10% of the intranasal formulation. A 0.1 mg tablet is equivalent to 2.5 to 5 mcg of the nasal spray. A sublingual form is available in 60, 120, and 240 mcg with improved bioavailability of approximately 60%. If intranasal or oral desmopressin cannot be administered, an injectable subcutaneous form can be given with typical doses of 1 mcg administered every 12 hours.
  2. Chlorpropamide enhances the effects of AVP or desmopressin. The efficacy of this agent is limited by the risk of inducing hypoglycemia.
  3. In mild cases of central DI, polyuria may be controlled with hydrochlorothiazide at daily doses of 25 to 50 mg.
  4. Carbamazepine at doses of 100 to 300 mg twice daily enhances tubular responsiveness to AVP, but is a rarely employed treatment.
  5. Clofibrate administered at 500 mg every 6 hours can lower urine output by enhancing AVP release.
  6. NSAIDs inhibit the synthesis of prostaglandins and antagonize AVP. Potential nephrotoxic effects of NSAIDs must be balanced against efficacy of this adjunctive therapy.
- Nephrogenic diabetes insipidus:
  1. Remove the underlying cause. In the case of prolonged lithium therapy, NDI may be permanent despite withdrawal of the offending agent.
  2. Amiloride can antagonize lithium-induced NDI.
  3. A low-sodium diet and thiazide diuretic represent additive therapies for NDI.

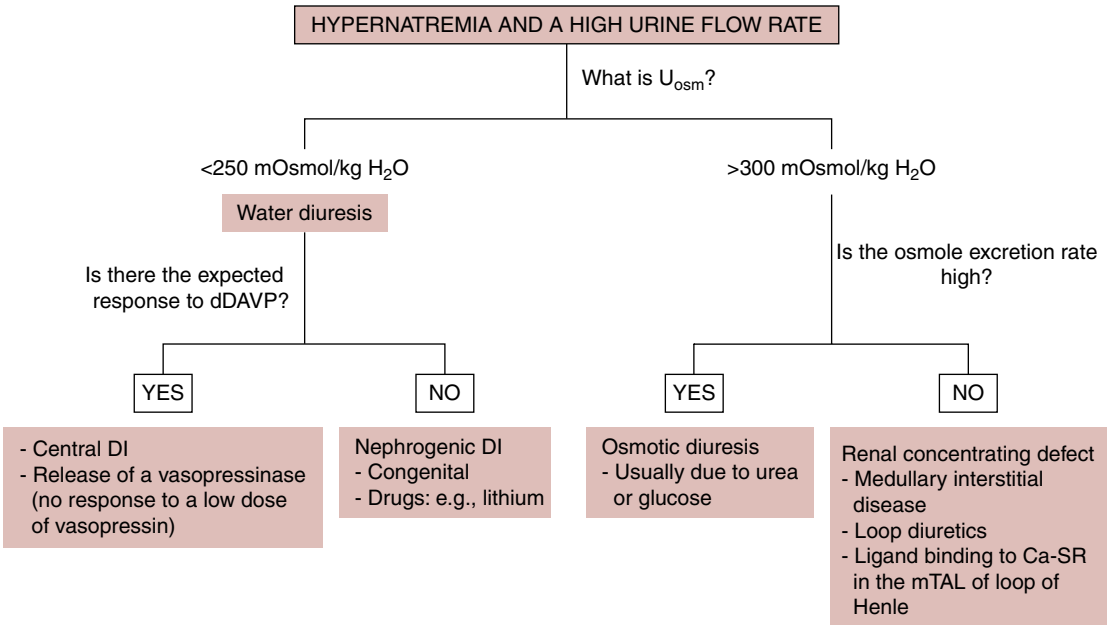

FIG. E1 Diagnostic flowchart for diabetes insipidus. The first step is to determine whether the water loss is caused by a water diuresis or an osmotic diuresis, or whether there is a renal concentrating defect. The principal tools are assessment of the U_{0sm} and calculation of the osmole excretion rate. In a patient with central diabetes insipidus (DI) or a water diuresis caused by the release of a vasopressinase, U_{0sm} should rise to a value that is higher than the P_{0sm} in response to the administration of desamino-D-arginine vasopressin (dDAVP). If not, nephrogenic DI is the basis of the water diuresis. A value of the U_{0sm} that is higher than 300 mOsm/kg of water suggests that the basis of hypernatremia is an osmotic diuresis if the osmole excretion rate is appreciably higher than 1000 mOsm/day or a renal concentrating defect if the osmole excretion rate is not high. Examples of ligand binding to the calcium sensing receptor (Ca-SR) in the medullary thick ascending limb (mTAL) of the loop of Henle include calcium ions in a patient with hypercalcemia and cationic drugs (e.g., gentamicin, cisplatin). (From Kamel et al: *Fluid, electrolyte, and acid-base physiology: a problem-based approach*, ed 5, Philadelphia, 2017, Elsevier, p 325.)

TABLE E4 Treatments for Diabetes Insipidus

Type of Diabetes Insipidus	Drug	Dose
Complete central	dDAVP	10-20 g intranasally every 12-24 hr
Partial central	Aqueous vasopressin	5-10 U subcutaneously every 4-6 hr
	Chlorpropamide	250-500 mg/day
	Clofibrate	500 mg 3-4× daily
	Carbamazepine	400-600 mg/day
Nephrogenic	Thiazide diuretics	5 mg/day
	NSAIDs	
	Amiloride (for lithium-related disease)	
Gestational	dDAVP	As for complete central

dDAVP, Desmopressin; *NSAIDs,* nonsteroidal anti-inflammatory drugs.
Adapted from Lanese D, Teitelbaum I: Hypernatremia. In Jacobson HR et al [eds]: *The principles and practice of nephrology*, Philadelphia, 1998, Mosby.

CHRONIC Rx

Patients should be aware of the danger of dehydration and need for liberal water intake.

REFERRAL

Endocrinology consultation for diagnostic testing

PEARLS & CONSIDERATIONS

COMMENTS

- Suspect DI when urine osmolality is lower than plasma osmolality in the setting of hypernatremia.
- Patients should be instructed to wear a medical identification tag or bracelet identifying their medical illness.
- In CDI, dDAVP represents the standard-of-care and is safe with prolonged use.
- The treatment of NDI is more complicated than CDI. Consultation with a specialist is always recommended in this setting.

PATIENT & FAMILY EDUCATION

BASIC INFORMATION

DEFINITION

- Diabetes mellitus (DM) refers to a syndrome of hyperglycemia resulting from many different causes (see "Etiology"). It is broadly classified into type 1 (T1DM) and type 2 DM (T2DM). The terms *insulin-dependent* and *non–insulin-dependent* diabetes are obsolete because when a person with type 2 diabetes needs insulin, he or she remains labeled as type 2 and is not reclassified as type 1. Immune-mediated type 1 DM (type 1A) represents 5% to 10% of newly diagnosed diabetics. Table 1 provides a general comparison of the two types of DM. One difference is that type 1 has usually complete or near-total knockout of insulin reserves mediated solely by immunogenic responses from carriers of certain genotypes, whereas type 2 is of polygenetic origin and may have patients who may start with hyperinsulinemia but have insulin resistance and through environmental factors such as diet and sedentary lifestyle leads to an imbalance between glucagon and insulin levels, resulting in combination of causes toward hyperglycemia.
- Some type 1 diabetics also may exhibit high levels of glucagon and not all type 1 diabetics have complete islet cell destruction.
- The classification of diabetes also includes:
  1. **LADA**: Latent autoimmune diabetes of adult onset (sometimes called type 1.5 DM). These individuals are typically not insulin dependent initially and are often misclassified as having type 2 DM.
  2. **MODY**: Maturity onset diabetes of youth. These have various genetic expressions and can be classified into various subtypes:
     a. MODY 1, 2, 3, 4, and 5 (with 3 being most prevalent: 70% incidence with HNF-1-alpha [12q24] genetic expression)
     b. MODY 7 and 8 (rare)
  3. Ketosis-prone diabetes: Relapsing/remitting beta cell function with slow deterioration over time. It presents with ketoacidosis requiring insulin, then regains beta cell function and patient is able to discontinue insulin. This form is most common under age 40, in those of African or Afro-Caribbean origin, and in obese or overweight patients.
  4. Secondary diabetes:
     a. Pancreatic disease or resection (e.g., cystic fibrosis)
     b. Chronic excessive corticosteroid exposure or Cushing syndrome
     c. Glucagonoma
     d. Acromegaly
     e. Other rare genetic disorders (e.g., mitochondrial diabetes MELAS syndrome)
  5. Rare autoimmune (e.g., type A and B insulin resistance syndrome)
- Diabetes mellitus can be diagnosed by the following tests:
  1. A hemoglobin A_{1c} (HbA_{1c}) value ≥6.5% is considered diagnostic for diabetes. This test is preferred because of ease of administration and reliability.
  2. A fasting plasma glucose (FPG) ≥126 mg/dl, which should be confirmed with repeat testing on a different day. Fasting is defined as no caloric intake for at least 8 hr.
  3. An oral glucose tolerance test (OGTT) with a plasma glucose ≥200 mg/dl 2 hr after a 75 g (100 g for pregnant women) glucose load.
  4. Symptoms of hyperglycemia and a casual (random) plasma glucose ≥200 mg/dl are also indicative of DM. Classic symptoms of hyperglycemia include polyuria, polydipsia, and unexplained weight loss. At the time of diagnosis as a diabetic, B-cell function is at 25% to 30%.
- Individuals with glucose levels higher than normal but not high enough to meet the criteria for diagnosis of DM are considered to have "prediabetes," the diagnosis of which is made as follows:
  1. A fasting plasma glucose 100 to 125 mg/dl; this is referred to as ***impaired fasting glucose.***
  2. After OGTT, a 2-hr plasma glucose of 140 to 199; this is referred to as ***impaired glucose tolerance.*** Patients with impaired glucose tolerance or prediabetes have B-cell function at 50% of normal.
  3. A hemoglobin A_{1c} value of 5.7% to 6.4%.
- Table 2 describes diagnostic categories for DM and at-risk states.

SYNONYMS

IDDM (insulin-dependent diabetes mellitus)
NIDDM (non–insulin-dependent diabetes mellitus)
Type 1 diabetes mellitus (insulin-dependent diabetes mellitus)
Type 2 diabetes mellitus (non–insulin-dependent diabetes mellitus)
LADA (latent autoimmune diabetes of adult)
MODY (mature onset diabetes of youth)

ICD-10CM CODES

E11.5	Type 2 diabetes mellitus with peripheral circulatory complications
E11.7	Type 2 diabetes mellitus with multiple complications
E11.8	Type 2 diabetes mellitus with unspecified complications
E11.9	Type 2 diabetes mellitus without complications
E10.69	Type 1 diabetes mellitus with other specified complication
E10.8	Type 1 diabetes mellitus with unspecified complications
E10.9	Type 1 diabetes mellitus without complications
E11.69	Type 2 diabetes mellitus with other specified complication
E11.8	Type 2 diabetes mellitus with unspecified complications
E11.9	Type 2 diabetes mellitus without complications

TABLE 1 General Comparison of the Two Types of Diabetes Mellitus

	Type 1	Type 2
Previous terminology	Insulin-dependent diabetes mellitus (IDDM), type I, juvenile-onset diabetes	Non–insulin-dependent diabetes mellitus, type II, adult-onset diabetes
Age of onset	Usually <30 yr, particularly childhood and adolescence, but any age	Usually >40 yr, but any age
Genetic predisposition	Moderate; environmental factors required for expression; 35%-50% concordance in monozygotic twins; several candidate genes proposed	Strong; 60%-90% concordance in monozygotic twins; many candidate genes proposed; some genes identified in maturity-onset diabetes of the young
Human leukocyte antigen associations	Linkage to DQA and DQB, influenced by DRB (3 and 4) (DR2 protective)	None known
Other associations	Autoimmune; Graves disease, Hashimoto thyroiditis, vitiligo, Addison disease, pernicious anemia	Heterogeneous group, ongoing subclassification based on identification of specific pathogenic processes and genetic defects
Precipitating and risk factors	Largely unknown; microbial, chemical, dietary, other	Age, obesity (central), sedentary lifestyle, previous gestational diabetes
Findings at diagnosis	85%-90% of patients have one and usually more autoantibodies to ICA512/IA-2/IA-2b, GAD_{65}, insulin (IAA)	Possibly complications (microvascular and macrovascular) caused by significant preceding asymptomatic period
Endogenous insulin levels	Low or absent	Usually present (relative deficiency), early hyperinsulinemia
Insulin resistance	Only with hyperglycemia	Mostly present
Prolonged fast	Hyperglycemia, ketoacidosis	Euglycemia
Stress, withdrawal of insulin	Ketoacidosis	Nonketotic hyperglycemia, occasionally ketoacidosis

GAD, Glutamic acid decarboxylase; *IA-2/IA-2b,* tyrosine phosphatases; *IAA,* insulin autoantibodies; *ICA,* islet cell antibody; *ICA512,* islet cell autoantigen 512 (fragment of IA-2).
From Andreoli TE (ed): *Cecil essentials of medicine,* ed 6, Philadelphia, 2005, WB Saunders.

TABLE 2 Diagnostic Categories*: Diabetes Mellitus and At-Risk States

Fasting Plasma Glucose Level	2-Hour (75-g) OGTT Result		
	<140 mg/dl	**140-199 mg/dl**	**≥200 mg/dl**
<100 mg/dl	Normal	IGT†	DM
100-125 mg/dl	IFG†	IGT† *and* IFG†	DM
≥126 mg/dl	DM	DM	DM
HbA_{1C} Level	**<5.7%**	**5.7-6.4%**	**≥6.5%**
	Normal	High-risk†	DM

*These diagnostic categories are based on the combined fasting plasma glucose level and a 2-hour, 75-g oral glucose tolerance test (OGTT) result. Note that a confirmed random plasma glucose level of 200 mg/dl or higher in the appropriate clinical setting is diagnostic of diabetes and precludes the need for further testing.
†May be referred to as prediabetes.
DM, Diabetes mellitus; *IFG,* impaired fasting glucose; *IGT,* impaired glucose tolerance; *OGTT*, oral glucose tolerance test.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

EPIDEMIOLOGY & DEMOGRAPHICS

- DM affects 9% to 10% of the U.S. population. Prevalence rates vary considerably by race/ethnicity. T1DM accounts for approximately 5% of diagnosed diabetes cases and is defined by the presence of one or more autoimmune markers. While incidence of diabetes in adolescents is mostly type 1, the rate of type 2 being diagnosed in adolescents has increased by 1.5 times in certain given areas. This seems to correlate with the epidemic of pediatric obesity.
- Incidence rate increases with age, varying from 2% in persons age 20 to 44 yr to 18% in persons 65 to 74 yr. T2DM can have a long presymptomatic phase, leading to a 4- to 7-yr delay in diagnosis. In the U.S. 1.2 million new cases of diabetes are diagnosed each yr, and 86 million have prediabetes. Currently, 30 million Americans have diabetes; with this current trend, it is predicted that by 2050 1 out of 3 Americans will be diabetic.
- Diabetes accounts for 8% of all legal blindness in the U.S. and is the leading cause of end-stage renal disease (ESRD). Approximately 40% of patients in a given dialysis center are diabetic.
- Patients with diabetes are 2 to 4 times more likely than nondiabetic patients to experience development of cardiovascular disease (CVD).

PHYSICAL FINDINGS & CLINCIAL PRESENTATION

- Physical examination varies with the presence of complications and may be normal in early stages.
- Diabetic retinopathy:
  1. Nonproliferative (background diabetic retinopathy):
     a. Initially: Microaneurysms, capillary dilation, waxy or hard exudates, dot and flame hemorrhages, arteriovenous shunts
     b. Advanced stage: Microinfarcts with cotton wool exudates, macular edema
  2. Proliferative retinopathy: Characterized by formation of new vessels, vitreous hemorrhages, fibrous scarring, and retinal detachment
- Cataracts and glaucoma occur with increased frequency in patients with diabetes.
- Diabetic macular edema: Swelling of the macula leading to loss of sharp vision in this part of the eye. People with this disorder usually already have retinopathy but may present separately as well.
- Diabetic neuropathy:
  1. Distal sensorimotor polyneuropathy:
     a. Symptoms include paresthesia, hyperesthesia, or burning pain involving bilateral distal extremities in a "stocking glove" distribution. This can progress to motor weakness and ataxia.
     b. Physical examination may reveal decreased pinprick sensation, decreased sensation to light touch, decreased vibration sense, and loss of proprioception. Motor disturbances such as decreased deep tendon reflexes and atrophy of interosseous muscles can also be seen.
  2. Autonomic neuropathy:
     a. GI disturbances: Esophageal motility abnormalities, gastroparesis, diarrhea (usually nocturnal):
        (1) Increased gastric emptying seen in type 2
        (2) Decreased gastric emptying seen in type 1
     b. Genitourinary (GU) disturbances: Neurogenic bladder (hesitancy, weak stream, and dribbling), impotence
     c. Cardiovascular (CV) disturbances: Orthostatic hypotension, tachycardia, decreased heart rate variability (HRV). Decreased heart rate variability is associated with increased cardiac mortality, independent of ejection fraction.
  3. Polyradiculopathy: Painful weakness and atrophy in the distribution of ≥1 contiguous nerve root.
  4. Mononeuropathy involving cranial nerves III, IV, or VI or peripheral nerves can also occur.
- Diabetic nephropathy: Pedal edema, pallor, weakness, uremic appearance
- Nephrotic syndrome: Proteinuria, hypertriglyceridemia, edema
